- Ignition off
- Disconnect the battery negative lead
- Reinstall the connectors, components etc.
- Ignition on
- Connect the battery negative lead.

> WARNING: **There must not be anyone inside the passenger compartment when the battery is connected.**

- Read off diagnostic trouble codes (DTCs).

The fault is no longer present if the diagnostic trouble code (DTC) status is intermittent.

Fig. 143: Identifying VCT2000 Diagnostic Tool Symbol In VIDA
Courtesy of VOLVO CARS CORPORATION

Is the diagnostic trouble code (DTC) intermittent?

- **YES**

  VERIFIED: Troubleshooting has been completed.

- **NO**

  See: **INFORMATION**

INFORMATION

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

SRS-0236: SWITCH FOR THE PASSENGER AIRBAG. FAULTY FUNCTION

(2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-0236

Condition

Fig. 144: Identifying Passenger Airbag Switch
Courtesy of VOLVO CARS CORPORATION

The supplemental restraint system module (SRS) checks the signal from the switch for the passenger airbag.

The diagnostic trouble code (DTC) is stored if the control module registers that the switch has an internal fault which causes incorrect operation.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I, II and III.

Substitute Value

- None.

Possible Source

- Fault in the switch for the passenger airbag.

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.

FAULTY FUNCTION

CHECKING THE COMPONENT

Fig. 145: Identifying Ignition OFF
Courtesy of VOLVO CARS CORPORATION

Fig. 146: Disconnecting Connector
Courtesy of VOLVO CARS CORPORATION

- Switch off the ignition. Wait 10 seconds
- Set the switch to the **ON** position
- Switch on the ignition. Wait 10 seconds.

  Check the current running through sensors A and B in the switch.

  When the switch is in the **ON** position, the current level in sensor A must be in the range of 1.6-6.4 mA and the current level in sensor B must be in the range of 12.8-20.1 mA.

  Use the VCT2000 (or appropriate scan tool) to read off the current level.

  Replace the switch if any of the current levels are outside the listed ranges.

- Switch off the ignition. Wait 10 seconds
- Set the switch to the **OFF** position
- Switch on the ignition. Wait 10 seconds.

Check the current running through sensors A and B in the switch.

When the switch is in the **OFF** position, the current level in sensor A must be in the range of 12.8-20.1 mA and the current level in sensor B must be in the range of 1.6-6.4 mA.

Use the VCT2000 (or appropriate scan tool) to read off the current level.

Replace the switch if any of the current levels are outside the listed ranges.

Erase the diagnostic trouble code (DTC) if fault is not found.

Other information

- see **CONTACT BREAKER PASSENGER AIRBAG (SRS), REPLACING** .

- **YES**

  VERIFIED: Troubleshooting has been completed.

- **NO**

  See: **INFORMATION**

INFORMATION

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

SRS-0237: SWITCH FOR THE PASSENGER AIRBAG. FAULTY SIGNAL (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-0237

Condition

Fig. 150: Identifying Passenger Airbag Switch
Courtesy of VOLVO CARS CORPORATION

The supplemental restraint system module (SRS) checks the signal from the switch for the passenger airbag.

The diagnostic trouble code (DTC) is stored if the control module registers a configuration fault.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- Incorrect switch installed
- Faulty software in the supplemental restraint system module (SRS).

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.

FAULTY SIGNAL

REPLACING THE COMPONENT

CAUTION: Do not touch the terminal pins in the supplemental restraint system module (SRS). There is a risk of static discharge. This could damage the supplemental restraint system module (SRS).

Fig. 151: Identifying Ignition OFF
Courtesy of VOLVO CARS CORPORATION

Fig. 152: Disconnecting Connector
Courtesy of VOLVO CARS CORPORATION

- Switch off the ignition. Wait 10 seconds
- Replace the switch for the passenger airbag.

Check the status of the diagnostic trouble code (DTC).

- Reinstall the connectors, components etc.
- Switch on the ignition. Wait 10 seconds
- Read off using the VCT2000 (or appropriate scan tool).

Read off the status of the diagnostic trouble code (DTC) using the VCT2000 (or appropriate scan tool).

The fault has been remedied if the diagnostic trouble code (DTC) is intermittent.

If the fault is still permanent, replace the supplemental restraint system module (SRS).

Remedy as necessary.

Other information

- To access or replace the switch for the passenger airbag and the connectors, see: **CONTACT BREAKER PASSENGER AIRBAG (SRS), REPLACING**
- see **SUPPLEMENTAL RESTRAINT SYSTEM MODULE (SRS), REPLACING**

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

SRS-0238: SWITCH FOR THE PASSENGER AIRBAG. FAULTY SIGNAL

(2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-0238

Condition

Fig. 156: Identifying Passenger Airbag Switch
Courtesy of VOLVO CARS CORPORATION

The supplemental restraint system module (SRS) checks the signal from the switch for the passenger airbag.

The diagnostic trouble code (DTC) is stored if the control module registers a faulty status signal.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- Fault in the switch for the passenger airbag
- Internal fault in the supplemental restraint system module (SRS).

Fault symptom[s]

- The SRS indicator lamp is lit
- PAD lamp lit.

FAULTY SIGNAL

REPLACING THE COMPONENT

CAUTION: Do not touch the terminal pins in the supplemental restraint system module (SRS). There is a risk of static discharge. This could damage the supplemental restraint system module (SRS).

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

SRS-0239: SWITCH FOR THE PASSENGER AIRBAG. CONFIGURATION

FAULT (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-0239

Condition

Fig. 162: Identifying Passenger Airbag Switch
Courtesy of VOLVO CARS CORPORATION

The supplemental restraint system module (SRS) checks the signal from the switch for the passenger airbag.

The diagnostic trouble code (DTC) is stored if the control module receives a signal to deactivate the passenger airbag.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- The supplemental restraint system module (SRS) receives a signal from the switch requesting

deactivation of the passenger airbag, even though the control module is programmed that there is no switch for the passenger airbag installed.

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.

FAULT-TRACING

see **FAULT-TRACING**

SRS-023A: SWITCH FOR THE PASSENGER AIRBAG. CONFIGURATION FAULT (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-023A

Condition

Fig. 163: Identifying Passenger Airbag Switch
Courtesy of VOLVO CARS CORPORATION

The supplemental restraint system module (SRS) checks the signal from the switch for the passenger airbag.

The diagnostic trouble code (DTC) is stored if the control module registers a configuration fault in the signal cable.

The diagnostic trouble code (DTC) can only be diagnosed when the ignition is switched on (12 V). In other words, the diagnostic trouble code (DTC) can only be diagnosed when the ignition is switched from position 0 to positions I, II or III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- The supplemental restraint system module (SRS) identifies that the switch for the passenger airbag is installed, despite the control module being programmed that it should not be installed.

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.

FAULT-TRACING

see **FAULT-TRACING**

SRS-0240: PASSENGER AIRBAG. ACTIVATION (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-0240

Condition

The supplemental restraint system module (SRS) checks the activation signal to the passenger airbag.

The diagnostic trouble code (DTC) is stored if the control module registers a fault in the activation signal.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- The supplemental restraint system module (SRS) identifies that the passenger airbag cannot be activated.

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.

ACTIVATION

REPLACING THE COMPONENT

CAUTION: Do not touch the terminal pins in the supplemental restraint system module (SRS). There is a risk of static discharge. This could damage the supplemental restraint system module (SRS).

Fig. 164: Identifying Ignition OFF
Courtesy of VOLVO CARS CORPORATION

Fig. 165: Disconnecting Connector
Courtesy of VOLVO CARS CORPORATION

- Switch off the ignition. Wait 10 seconds.

  For vehicles with a switch for the passenger airbag:

  - Replace the switch for the passenger airbag.

  Then check the status of the diagnostic trouble code (DTC).

  - Reinstall the connectors, components etc.
  - Switch on the ignition. Wait 10 seconds
  - Read off using the VCT2000 (or appropriate scan tool).

Read off the status of the diagnostic trouble code (DTC) using the VCT2000 (or appropriate scan tool).

The fault has been remedied if the diagnostic trouble code (DTC) is intermittent.

If the fault is still permanent, replace the supplemental restraint system module (SRS).

Remedy as necessary.

On vehicles that do not have a switch for the passenger airbag, replace the supplemental restraint system module (SRS).

Other information

- To access or replace the switch for the passenger airbag and the connectors, see: **CONTACT BREAKER PASSENGER AIRBAG (SRS), REPLACING**

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

SRS-0253: OCCUPANT WEIGHT SENSOR (OWS). COMMUNICATION FAULT (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-0253

Condition

Fig. 186: Identifying Occupant Weight Sensor (OWS) Assembly
Courtesy of VOLVO CARS CORPORATION

The supplemental restraint system module (SRS) checks the signal from the occupant weight sensor (OWS).

The diagnostic trouble code (DTC) is stored if the control module registers a communication fault.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- Open-circuit in the signal cable or in the connectors between the occupant weight sensor (OWS) and supplemental restraint system module (SRS)
- Damaged occupant weight sensor (OWS).

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.

COMMUNICATION FAULT

CHECKING THE COMPONENT

Fig. 187: Identifying Ignition OFF
Courtesy of VOLVO CARS CORPORATION

Fig. 188: Disconnecting Connector
Courtesy of VOLVO CARS CORPORATION

- Switch off the ignition. Wait 10 seconds
- Disconnect the 10-pin connector from the occupant weight sensor (OWS)
- Disconnect the connector from the supplemental restraint system module (SRS).

CAUTION: Do not touch the terminal pins in the supplemental restraint system module (SRS) and the occupant weight sensor (OWS). There is a risk of static discharge. This could damage the supplemental restraint system module (SRS) and the occupant weight sensor (OWS).

Check the connectors for the supplemental restraint system module (SRS) and the occupant weight sensor (OWS). Check for damage to pins and terminals in the connectors. Check for contact resistance.

Also check the other connectors that connect the communication cable between the supplemental restraint system module (SRS) and the occupant weight sensor (OWS).

Remedy as necessary.

Check the communication cable (LIN-bus) between the supplemental restraint system module (SRS) and the 10-pin connector for the occupant weight sensor (OWS). Check for an open-circuit.

Check the cable between supplemental restraint system module (SRS) terminal #57 and the 10-pin connector for occupant weight sensor (OWS) terminal #10.

Remedy as necessary.

Replace the pressure sensor and the occupant weight sensor module (OWS) if no fault is detected. The pressure sensor and occupant weight sensor (OWS) module are included in the occupant weight sensor (OWS) system.

NOTE: **After replacing the pressure sensor and the occupant weight sensor (OWS) module in the occupant weight sensor (OWS) system, the supplemental restraint system module (SRS) must be configured. This is done by storing the ID number for the occupant weight sensor (OWS).**

The occupant weight sensor (OWS) must also be calibrated.

- Switch off the ignition. Wait 10 seconds
- Disconnect the 10-pin connector from the occupant weight sensor (OWS)
- Disconnect the connector from the supplemental restraint system module (SRS).

CAUTION: Do not touch the terminal pins in the supplemental restraint system module (SRS) and the occupant weight sensor (OWS). There is a risk of static discharge which could damage the control modules.

Check the connectors for the supplemental restraint system module (SRS) and the occupant weight sensor (OWS). Check for damage to pins and terminals in the connectors. Check for contact resistance.

Also check the other connectors that connect the communication cable between the supplemental restraint

system module (SRS) and the occupant weight sensor (OWS).

Remedy as necessary.

Check the communication cable (LIN-bus) between the supplemental restraint system module (SRS) and the 10-pin connector for the occupant weight sensor (OWS). Check for an open-circuit.

Check the cable between supplemental restraint system module (SRS) terminal #57 and the 10-pin connector for occupant weight sensor (OWS) terminal #10.

Remedy as necessary.

Replace the pressure sensor and the occupant weight sensor module (OWS) if no fault is detected. The pressure sensor and occupant weight sensor (OWS) module are included in the occupant weight sensor (OWS) system.

NOTE: **After replacing the pressure sensor and the occupant weight sensor (OWS) module in the occupant weight sensor (OWS) system, the supplemental restraint system module (SRS) must be configured. This is done by storing the ID number for the occupant weight sensor (OWS).**

The occupant weight sensor (OWS) must also be calibrated.

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

SRS-0256: OCCUPANT WEIGHT SENSOR (OWS). INTERNAL FAULT (2005-

2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-0256

Condition

Fig. 198: Identifying Occupant Weight Sensor (OWS) Assembly
Courtesy of VOLVO CARS CORPORATION

The supplemental restraint system module (SRS) checks the signal from the occupant weight sensor (OWS).

The diagnostic trouble code (DTC) is stored if the control module registers an internal fault in the occupant weight sensor (OWS).

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- Internal fault in the occupant weight sensor (OWS).

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.

INTERNAL FAULT

REPLACING THE COMPONENT

Fig. 199: Identifying Ignition OFF
Courtesy of VOLVO CARS CORPORATION

- Switch off the ignition. Wait 10 seconds.

CAUTION: Avoid touching the terminal pins in the occupant weight sensor

(OWS). There is a risk of static discharge which could damage the occupant weight sensor (OWS).

Replace the pressure sensor and the occupant weight sensor (OWS) module. The pressure sensor and occupant weight sensor (OWS) module are included in the occupant weight sensor (OWS) system.

NOTE: **After replacing the pressure sensor and the occupant weight sensor (OWS) module in the occupant weight sensor (OWS) system, the supplemental restraint system module (SRS) must be configured. This is done by storing the ID number for the occupant weight sensor (OWS).**

The occupant weight sensor (OWS) must also be calibrated.

SRS-0258: OCCUPANT WEIGHT SENSOR (OWS). CALIBRATION FAULT

(2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-0258

Condition

Fig. 202: Identifying Occupant Weight Sensor (OWS) Assembly
Courtesy of VOLVO CARS CORPORATION

The supplemental restraint system module (SRS) checks the signal from the occupant weight sensor (OWS).

The diagnostic trouble code (DTC) is stored if the control module registers a calibration fault.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- Incorrect calibration of the occupant weight sensor (OWS).

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.

CALIBRATION FAULT

REPLACING THE COMPONENT

Fig. 203: Identifying Ignition OFF
Courtesy of VOLVO CARS CORPORATION

- Switch off the ignition. Wait 10 seconds

CAUTION: Avoid touching the terminal pins in the occupant weight sensor

(OWS). There is a risk of static discharge which could damage the occupant weight sensor (OWS).

If this diagnostic trouble code (DTC) is generated after unsuccessful calibration of the occupant weight sensor (OWS):

- Recalibrate the occupant weight sensor (OWS).

If the diagnostic trouble code (DTC) was set at another point:

- Replace the pressure sensor and the occupant weight sensor (OWS) module. The pressure sensor and occupant weight sensor (OWS) module are included in the occupant weight sensor (OWS) system.

NOTE: **After replacing the pressure sensor and the occupant weight sensor (OWS) module in the occupant weight sensor (OWS) system, the supplemental restraint system module (SRS) must be configured. This is done by storing the ID number for the occupant weight sensor (OWS).**

The occupant weight sensor (OWS) must also be calibrated.

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

SRS-0259: OCCUPANT WEIGHT SENSOR. SIGNAL MISSING (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-0259

Condition

Fig. 206: Identifying Occupant Weight Sensor (OWS) Assembly
Courtesy of VOLVO CARS CORPORATION

The supplemental restraint system module (SRS) checks the LIN signal from the occupant weight sensor (OWS).

The diagnostic trouble code (DTC) is stored if the control module detects that:

The voltage from the Occupant weight sensor (OWS) is too low or is missing.

The control module's test for the diagnostic trouble code (DTC) starts in the event of:

Ignition position I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- Open-circuit in the signal cable (LIN-bus) or in the connectors between the supplemental restraint system module (SRS) and the occupant weight sensor (OWS).
- Damaged occupant weight sensor (OWS).

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.
- SRS warning message displayed

FAULTY COMMUNICATION

CHECKING THE COMPONENT

Fig. 207: Identifying Ignition OFF

Courtesy of VOLVO CARS CORPORATION

Fig. 208: Disconnecting Connector
Courtesy of VOLVO CARS CORPORATION

- Switch off the ignition. Wait 10 seconds
- Disconnect the 10-pin connector from the occupant weight sensor (OWS)
- Disconnect connector A from the central electronic module (CEM).

CAUTION: Do not touch the terminal pins in the supplemental restraint system module (SRS), the central electronic module (CEM) and the occupant weight sensor (OWS). There is a risk of static discharge which could damage the control modules.

Check the connectors for the central electronic module (CEM) and the occupant weight sensor (OWS).

Check for damage to pins and terminals in the connectors. Check for contact resistance.

Also check the other connectors that connect the power supply cable between the central electronic module (CEM) and the occupant weight sensor (OWS).

Remedy as necessary.

Check the power supply cable between the central electronic module (CEM) and the connector for the occupant weight sensor (OWS). Check for an open-circuit. Check the fuse.

Check the cable between:

- Central electronic module (CEM) terminal #A10 and the 10-pin connector for occupant weight sensor (OWS) terminal #2.

Remedy as necessary.

Check the ground connection for the occupant weight sensor (OWS). Check for an open-circuit. Check for contact resistance.

Check the cable between the 10-pin connector for the occupant weight sensor (OWS) terminal #9 and the ground terminal.

Remedy as necessary.

Disconnect the connector from the supplemental restraint system module (SRS). Check the communication cable (LIN-bus) between the supplemental restraint system module (SRS) and the 10-pin connector for the occupant weight sensor (OWS). Check for an open-circuit.

Check the cable between:

- Supplemental restraint system module (SRS) terminal #57 and the 10-pin connector for occupant weight sensor (OWS) terminal #10.

Remedy as necessary.

Replace the pressure sensor and the occupant weight sensor module (OWS) if no fault is detected. The pressure sensor and occupant weight sensor (OWS) module are included in the occupant weight sensor (OWS) system.

NOTE: **After replacing the pressure sensor and the occupant weight sensor (OWS) module in the occupant weight sensor (OWS) system, the supplemental restraint system module (SRS) must be configured. This is done by storing the ID number for the occupant weight sensor (OWS).**

The occupant weight sensor (OWS) must also be calibrated.

SRS-025F: OCCUPANT WEIGHT SENSOR (OWS). SIGNAL TOO LOW (2005-

2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-025F

Condition

Fig. 240: Identifying Occupant Weight Sensor (OWS) Assembly
Courtesy of VOLVO CARS CORPORATION

The supplemental restraint system module (SRS) checks the signal from the occupant weight sensor (OWS).

The diagnostic trouble code (DTC) is stored if the control module receives a message indicating that the voltage is too low in the occupant weight sensor (OWS).

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- Damaged occupant weight sensor (OWS).

- Short-circuit to ground in the signal cable or in the connectors between the components in the occupant weight sensor (OWS).

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.

SIGNAL TOO LOW

CHECKING THE COMPONENT AND WIRING

Fig. 241: Identifying Ignition OFF
Courtesy of VOLVO CARS CORPORATION

- Switch off the ignition. Wait 10 seconds.
- Unplug the 10-pin connector from the occupant weight sensor (OWS).
- Unplug the 3-pin connector from the pressure sensor.

CAUTION: Avoid touching the terminal pins in the occupant weight sensor (OWS). There is a risk of static discharge which could damage the occupant weight sensor (OWS).

Check the connectors between the pressure sensor and the occupant weight sensor (OWS) for damaged pins and connections.

Remedy as necessary.

Check the leads between pressure sensor and the occupant weight sensor (OWS) for short-circuiting to voltage/ground and open circuit.

Remedy as necessary.

INFORMATION

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

SRS-0260: OCCUPANT WEIGHT SENSOR (OWS). SIGNAL TOO HIGH (2005-

2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-0260

Condition

Fig. 244: Identifying Occupant Weight Sensor (OWS) Assembly
Courtesy of VOLVO CARS CORPORATION

The supplemental restraint system module (SRS) checks the signal from the occupant weight sensor (OWS).

The diagnostic trouble code (DTC) is stored if the control module receives a message indicating that the voltage is too high in the occupant weight sensor (OWS).

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- Damaged occupant weight sensor (OWS).

- Short-circuit to supply voltage in the signal cable or in the connectors between the components in the occupant weight sensor (OWS).

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.

SIGNAL TOO HIGH

CHECKING THE WIRING AND TERMINALS

- Ignition off, wait for 15 seconds.
- Unplug the 10-pin connector from the occupant weight sensor (OWS).
- Unplug the 3-pin connector from the pressure sensor.

CAUTION: Avoid touching the contact pin of the occupant weight sensor (OWS). Risk of electrostatic discharge that may cause damage in occupant weight sensor (OWS).

Check the connectors between the pressure sensor and the occupant weight sensor (OWS) for damaged pins and connections.

Remedy as necessary.

Check the leads between pressure sensor and the occupant weight sensor (OWS) for short-circuiting to voltage/ground and open circuit.

Remedy as necessary.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

SRS-0261: OCCUPANT WEIGHT SENSOR. SIGNAL MISSING (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-0261

Condition

Fig. 248: Identifying Occupant Weight Sensor (OWS) Assembly
Courtesy of VOLVO CARS CORPORATION

The supplemental restraint system module (SRS) checks the LIN signal from the occupant weight sensor (OWS).

The diagnostic trouble code (DTC) is stored if the control module detects that:

The voltage from the Occupant weight sensor (OWS) is too low or is missing.

The control module's test for the diagnostic trouble code (DTC) starts in the event of:

Ignition position I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- Open-circuit in the signal cable (LIN-bus) or in the connectors between the supplemental restraint system module (SRS) and the occupant weight sensor (OWS).
- Damaged occupant weight sensor (OWS).

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.
- SRS warning message displayed

SIGNAL TOO LOW

see **SIGNAL TOO LOW**

SRS-0262: OCCUPANT WEIGHT SENSOR (OWS). INCORRECT DATA (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-0262

Condition

Fig. 249: Identifying Occupant Weight Sensor (OWS) Assembly

Courtesy of VOLVO CARS CORPORATION

The supplemental restraint system module (SRS) checks the signal from the occupant weight sensor (OWS).

The diagnostic trouble code (DTC) is stored if the control module receives a message containing incorrect data.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- Damaged component in the occupant weight sensor (OWS).

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.

INCORRECT DATA

REPLACING THE COMPONENT

Fig. 250: Identifying Ignition OFF
Courtesy of VOLVO CARS CORPORATION

- Switch off the ignition. Wait 10 seconds.

CAUTION: Avoid touching the terminal pins in the occupant weight sensor (OWS). There is a risk of static discharge which could damage the occupant weight sensor (OWS).

Replace the pressure sensor and the occupant weight sensor (OWS) module. The pressure sensor and occupant weight sensor (OWS) module are included in the occupant weight sensor (OWS) system.

NOTE: After replacing the pressure sensor and the occupant weight sensor (OWS) module in the occupant weight sensor (OWS) system, the supplemental restraint system module (SRS) must be configured. This is

done by storing the ID number for the occupant weight sensor (OWS).

The occupant weight sensor (OWS) must also be calibrated.

INFORMATION

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

SRS-DD00: CONTROL MODULE COMMUNICATION. FAULTY

COMMUNICATION (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-DD00

Condition

The supplemental restraint system module (SRS) checks communication between the control module and the occupant weight sensor (OWS).

The diagnostic trouble code (DTC) is stored if the control module registers a communication fault.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- Damage to the signal cable (LIN-bus) or in the connectors between the supplemental restraint system module (SRS) and the occupant weight sensor (OWS)
- Damaged occupant weight sensor (OWS).

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.

FAULTY COMMUNICATION

CHECKING THE COMPONENT

Fig. 253: Identifying Ignition OFF
Courtesy of VOLVO CARS CORPORATION

Fig. 254: Disconnecting Connector
Courtesy of VOLVO CARS CORPORATION

- Switch off the ignition. Wait 10 seconds
- Disconnect the 10-pin connector from the occupant weight sensor (OWS)
- Disconnect the connector from the supplemental restraint system module (SRS).

CAUTION: Do not touch the terminal pins in the supplemental restraint system module (SRS) and the occupant weight sensor (OWS). There is a risk of static discharge which could damage the control modules.

Check the connectors for the supplemental restraint system module (SRS) and the occupant weight sensor (OWS). Check for damage to pins and terminals in the connectors. Check for contact resistance.

Also check the other connectors that connect the communication cable between the supplemental restraint

system module (SRS) and the occupant weight sensor (OWS).

Remedy as necessary.

Check the communication cable (LIN-bus) between the supplemental restraint system module (SRS) and the 10-pin connector for the occupant weight sensor (OWS). Check for an open-circuit.

Check the cable between supplemental restraint system module (SRS) terminal #57 and the 10-pin connector for occupant weight sensor (OWS) terminal #10.

Remedy as necessary.

If no fault is found, replace the supplemental restraint system module (SRS).

Remedy as necessary.

Replace the pressure sensor and the occupant weight sensor module (OWS) if a fault is still not detected. The pressure sensor and occupant weight sensor (OWS) module are included in the occupant weight sensor (OWS) system.

NOTE: **After replacing the pressure sensor and the occupant weight sensor (OWS) module in the occupant weight sensor (OWS) system, the supplemental restraint system module (SRS) must be configured. This is done by storing the ID number for the occupant weight sensor (OWS).**

The occupant weight sensor (OWS) must also be calibrated.

  See: **INFORMATION**

INFORMATION

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

SRS-DD01: COMMUNICATION CONTROL MODULE. SIGNAL TOO HIGH /

SIGNAL TOO LOW (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-DD01

Condition

The supplemental restraint system module (SRS) checks communication between the control module and the occupant weight sensor (OWS).

The diagnostic trouble code (DTC) is stored if the control module registers a communication fault.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- Short-circuit to supply voltage or ground in the signal cable (LIN-bus) or in the connectors between the supplemental restraint system module (SRS) and the occupant weight sensor (OWS).

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.

SIGNAL TOO HIGH / SIGNAL TOO LOW

CHECKING THE COMPONENT

Fig. 258: Identifying Ignition OFF
Courtesy of VOLVO CARS CORPORATION

Fig. 259: Disconnecting Connector
Courtesy of VOLVO CARS CORPORATION

- Switch off the ignition. Wait 10 seconds
- Disconnect the 10-pin connector from the occupant weight sensor (OWS)
- Disconnect the connector from the supplemental restraint system module (SRS).

CAUTION: Do not touch the terminal pins in the supplemental restraint system module (SRS) and the occupant weight sensor (OWS). There is a risk of static discharge which could damage the control modules.

Check the connectors for the occupant weight sensor (OWS) and the supplemental restraint system module (SRS). Check for damage to pins and terminals in the connectors.

Also check the other connectors that connect the communication cable between the supplemental restraint

system module (SRS) and the occupant weight sensor (OWS).

Remedy as necessary.

Check the communication cable (LIN-bus) between the supplemental restraint system module (SRS) and the 10-pin connector for the occupant weight sensor (OWS). Check for a short-circuit to ground. Check for a short-circuit to supply voltage.

Check the cable between supplemental restraint system module (SRS) terminal #57 and the 10-pin connector for occupant weight sensor (OWS) terminal #10.

Remedy as necessary.

If no fault is found, replace the supplemental restraint system module (SRS).

Remedy as necessary.

Replace the pressure sensor and the occupant weight sensor module (OWS) if a fault is still not detected. The pressure sensor and occupant weight sensor (OWS) module are included in the occupant weight sensor (OWS) system.

NOTE: **After replacing the pressure sensor and the occupant weight sensor (OWS) module in the occupant weight sensor (OWS) system, the supplemental restraint system module (SRS) must be configured. This is done by storing the ID number for the occupant weight sensor (OWS).**

The occupant weight sensor (OWS) must also be calibrated.

  See: **INFORMATION**

INFORMATION

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

SRS-DD02: COMMUNICATION CONTROL MODULE. FAULTY

COMMUNICATION (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-DD02

Condition

The supplemental restraint system module (SRS) checks communication between the control module and the occupant weight sensor (OWS).

The diagnostic trouble code (DTC) is stored if the control module registers a communication fault.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- Damage to the signal cable (LIN-bus) or in the connectors between the supplemental restraint system module (SRS) and the occupant weight sensor (OWS)
- Damaged occupant weight sensor (OWS).

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.

FAULTY COMMUNICATION

CHECKING THE COMPONENT

Fig. 263: Identifying Ignition OFF
Courtesy of VOLVO CARS CORPORATION

Fig. 264: Disconnecting Connector
Courtesy of VOLVO CARS CORPORATION

- Switch off the ignition. Wait 10 seconds
- Disconnect the 10-pin connector from the occupant weight sensor (OWS)
- Disconnect the connector from the supplemental restraint system module (SRS).

CAUTION: Do not touch the terminal pins in the supplemental restraint system module (SRS) and the occupant weight sensor (OWS). There is a risk of static discharge which could damage the control modules.

Check the connectors for the supplemental restraint system module (SRS) and the occupant weight sensor (OWS). Check for damage to pins and terminals in the connectors. Check for contact resistance.

Also check the other connectors that connect the communication cable between the supplemental restraint

system module (SRS) and the occupant weight sensor (OWS).

Remedy as necessary.

Check the communication cable (LIN-bus) between the supplemental restraint system module (SRS) and the 10-pin connector for the occupant weight sensor (OWS). Check for an open-circuit.

Check the cable between supplemental restraint system module (SRS) terminal #57 and the 10-pin connector for occupant weight sensor (OWS) terminal #10.

Remedy as necessary.

Replace the pressure sensor and the occupant weight sensor module (OWS) if no fault is detected. The pressure sensor and occupant weight sensor (OWS) module are included in the occupant weight sensor (OWS) system.

NOTE: **After replacing the pressure sensor and the occupant weight sensor (OWS) module in the occupant weight sensor (OWS) system, the supplemental restraint system module (SRS) must be configured. This is done by storing the ID number for the occupant weight sensor (OWS).**

The occupant weight sensor (OWS) must also be calibrated.

INFORMATION

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

SRS-DD10: COMMUNICATION CONTROL MODULE. FAULTY

COMMUNICATION (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-DD10

Condition

The supplemental restraint system module (SRS) checks communication between the control module and the occupant weight sensor (OWS).

The diagnostic trouble code (DTC) is stored if the control module registers a communication fault.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I, II and III.

Substitute Value

- Passenger airbag is deactivated.

Possible Source

- Open-circuit in the signal cable (LIN-bus) or in the connectors between the supplemental restraint system module (SRS) and the occupant weight sensor (OWS).

Fault symptom[s]

- SRS indicator lamp lit
- PAD lamp lit.

FAULTY COMMUNICATION

see **FAULTY COMMUNICATION**

SRS-E001: CONTROL MODULE COMMUNICATION. FAULTY COMMUNICATION (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-E001

Condition

Fig. 268: Identifying SRS Control Module
Courtesy of VOLVO CARS CORPORATION

The control modules transmit and receive information via a standardized serial communication method - CAN (Controller Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference (CAN communication blocked).

NOTE: In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the fault if it is intermittent.

Substitute Value

- The control module shuts itself off ("bus-off").

  HINT: The control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

Possible Source

- Short-circuit between the control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Internal fault in the control module

- Internal fault in another control module in the same part of the control area network (CAN).

Fault symptom[s]

- The SRS indicator lamp is lit.

SIGNAL MISSING

SRS-E003: CONFIGURATION FAULT. FAULTY CONFIGURATION (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION SRS-E003

Condition

Fig. 269: Identifying SRS Control Module
Courtesy of VOLVO CARS CORPORATION

The control module compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the control module and the central electronic module (CEM) is interrupted.

NOTE: **In the event of open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic command, however normal control area network (CAN) communication does not work. ("Expulsion mode")**

Substitute Value

- None.

Possible Source

- Faulty control area network (CAN) configuration ID. (The node is not intended for this car, for example a used control module with different software/hardware.)

- Open-circuit in the control area network (CAN) wiring between the control module and the central electrical module (CEM).

Fault symptom[s]

- The SRS indicator lamp is lit.

SIGNAL MISSING

ACCESSORIES AND BODY, CAB

Interior Equipment - Installation instructions, accessories

BABY INSERT, CHILD SEAT (2003-2005)

BABY INSERT, CHILD SEAT

Applies To 5-Point Seat Belts

Fig. 1: Identifying Shoulder Straps And Holes
Courtesy of VOLVO CARS CORPORATION

- Release upholstery at upper edge and pull forward.
- Note which group of holes the shoulder straps are routed through.
- Remove the shoulder straps (1) by pulling through the holes.

Applies To 5-Point Seat Belts

Fig. 2: Identifying Shoulder Strap, Locking Washers And Holes
Courtesy of VOLVO CARS CORPORATION

- Install the baby insert.
- At the appropriate height thread the shoulder straps through the holes in insert, upholstery and seat back.
- Thread the shoulder strap locking washers through the holes as illustrated.
- Check that the locking washers are correctly positioned.

Applies To 5-Point Seat Belts

Fig. 3: Fold Upholstery Back And Press Into Place With Two Clips
Courtesy of VOLVO CARS CORPORATION

- Fold the upholstery back and press into place with the two clips.
- Straighten the upholstery.

Applies To 4-Point Seat Belts

Fig. 4: Identifying Child Seat Harness Threaded Through Holes In Baby Insert
Courtesy of VOLVO CARS CORPORATION

- Thread the child seat harness through the holes in the baby insert.

Applies To 4-Point Seat Belts

Fig. 5: Baby Insert Positioned Correctly In Child Seat
Courtesy of VOLVO CARS CORPORATION

- Position the baby insert correctly in the child seat and pull the harness lap belt forward.

Applies To Both The Belts

Fig. 6: Adjust Baby Insert According To Child's Height By Moving The Upper Collar Upwards Or Downwards
Courtesy of VOLVO CARS CORPORATION

- Adjust the baby insert according to the child's height by moving the upper collar upwards or downwards.

CARGO NET, CARGO COMPARTMENT FLOOR (2003-2004)

CARGO NET, CARGO COMPARTMENT FLOOR

INSTALL

Fig. 7: Hook The Hooks Onto The Four Mounting Eyelets
Courtesy of VOLVO CARS CORPORATION

- Hook the hooks onto the four mounting eyelets
- Ensure that the two longest sides of the net cross the cargo compartment floor
- The net label (1) must be positioned opposite the tailgate opening.

Fig. 8: Identifying Hooks And Mounting Eyelets
Courtesy of VOLVO CARS CORPORATION

- To remove the cargo net: Unhook the hooks from the eyelets.

COOLBOX (2003-2004)

COOLBOX

USAGE

XC90, Second Row Of Seats

Fig. 9: Position Coolbox In Cargo Compartment Behind Backrest - XC90, Second Row Of Seats
Courtesy of VOLVO CARS CORPORATION

XC90, Third Row Of Seats

Fig. 10: Position Coolbox In Cargo Compartment Behind Backrest - XC90, Third Row Of Seats
Courtesy of VOLVO CARS CORPORATION

- Position the coolbox in the cargo compartment behind the backrest, as illustrated.

INSTALL

- Install the long strap hook in the left front (XC90 3rd row of rear seats) mounting eyelet (1) in the cargo compartment. Allow the strap lock (2) to hang over the right hand side of the coolbox as illustrated
- Press the mounting (3) down into the handle of the coolbox
- Install the short strap hook in the right hand front mounting eyelet (4) in the cargo compartment
- Lock the straps together. Tighten so that the coolbox is secured in place.

NOTE: Read the warning text on the coolbox.

- Connect the coolbox to the electrical socket in the cargo compartment
- Check the function.

FIRE EXTINGUISHER (2003-2008)

FIRE EXTINGUISHER

CAUTION: When installing the fire extinguisher in front of the front seats, the handle for the fire extinguisher must be turned to the left (looking towards the front of the car).

NOTE: When using an RTI unit in the XC90 the fire extinguisher must be mounted under the right-hand seat.

REMOVE

Fig. 11: Removal Of Fire Extinguisher From Mounting
Courtesy of VOLVO CARS CORPORATION

- Remove the fire extinguisher from the mounting.

INSTALL

Fig. 12: Identifying Installation Of New Handle
Courtesy of VOLVO CARS CORPORATION

- Raise the driver's seat to its highest point.

Applies To Manual Seats

- Release the catches (1). Remove the handle (2)
- Install the new handle (3).

Fig. 13: Cut Off Tie Strap Securing Cable Harness In Left-Hole In Seat Frame
Courtesy of VOLVO CARS CORPORATION

Applies To Power Seats

- Cut off the tie strap securing the cable harness in the left-hole in the seat frame (1).

Fig. 14: Identifying Bracket In Front Of Seat Frame
Courtesy of VOLVO CARS CORPORATION

Applies to manual seats from chassis number 415 000 inclusive

- Screw the bracket (1) into place in the existing holes in the front of the seat frame. Tighten to **10 Nm (8 lbf. ft)**
- Install the holder (2) on the bracket (1).

Applies to power seats

- Install a tie strap from the kit for the cable harness in the hole (3) on the bracket (1).

Applies to all car models

- Position the fire extinguisher in the holder. Hook the tensioner in the eyelet, tighten the strap and lock
- Read the fire extinguisher instructions.

INSTALLATION KIT CHILD SEAT (2003-2011)

INSTALLATION KIT CHILD SEAT

WARNING: This installation kit must NOT be mounted on the front seat on the passenger side in cars equipped with Supplemental Restraint System Module (SRS) (airbag). Child seats must NOT be mounted in the front seat on the passenger side in cars equipped with Supplemental Restraint System Module (SRS) (airbag).

NOTE: It is recommended that this installation is carried out at a Volvo workshop.

REMOVE

Fig. 15: Remove The Center Console's Right-Hand Side Panel
Courtesy of VOLVO CARS CORPORATION

- Remove the right-hand side panel from the center console by pulling it off. Start at the front edge and then work backwards until all the clips have released.

Fig. 16: Right-Hand Front Door Sill Trim Panel
Courtesy of VOLVO CARS CORPORATION

- Remove the sill trim panel for the right-hand front door. Pull it off, starting at the front edge, until the clip there has released. Continue backwards until the remaining clips have released
- Move the sill trim panel to the right in order to fold the carpet away from the right-hand side of the bodywork.

INSTALLING THE RIGHT-HAND MOUNTING

Fig. 17: Identifying Existing Hole In The Bodywork
Courtesy of VOLVO CARS CORPORATION

- Push the floor carpet to one side
- Enlarge the existing hole (1) in the bodywork. Use a **13 mm (33/64")** diameter drill bit
- Smooth off and rust-proof the edges of the hole.

Fig. 18: View Of Rivet Nut On The Rivet Nut Tool (P/N 9512782)
Courtesy of VOLVO CARS CORPORATION

- Take the rivet nut from the kit. Place the rivet nut on the rivet nut tool (P/N 9512782). Install the rivet nut in the drilled hole using the tool. Secure the rivet nut to the bodywork.

Fig. 19: Identifying Mounting To The Rivet Nut
Courtesy of VOLVO CARS CORPORATION

- Take the mounting and the M10 and M6 screws from the kit. Secure the mounting to the rivet nut. Secure the weld nut in the bodywork. Tighten the M10 screw. Tighten to **50 Nm (37 lbf. ft.)** . Tighten the M6 screw. Tighten to **10 Nm (7 lbf. ft.)**
- If the car has a passenger compartment connector socket, its bracket must be positioned above the mounting. Secure using the M6 screw.

Fig. 20: Position Lower Edge Of Mounting Eyelet
Courtesy of VOLVO CARS CORPORATION

- Fold back the carpet under the mounting. Using a pen, mark on the carpet the position of the lower edge of the mounting eyelet.

Fig. 21: View Of Cutting Marked Point
Courtesy of VOLVO CARS CORPORATION

- Use a carpet knife. Cut vertically upwards from the marked point. Cut equal to the width of the mounting eyelet.

Fig. 22: Reinstall The Sill Trim Panel
Courtesy of VOLVO CARS CORPORATION

- Fold back the carpet. Reinstall the sill trim panel.

INSTALLING THE LEFT-HAND MOUNTING

Fig. 23: Identifying Air Duct Screws
Courtesy of VOLVO CARS CORPORATION

- Push the floor carpet to one side where the side panel was removed
- Remove the two screws (1) in front of the air duct. Place the screws to one side. They will not be used again. There are new screws in the kit.

Fig. 24: View Of Mounting To Bodywork
Courtesy of VOLVO CARS CORPORATION

- Take the mounting and two M8 screws from the kit. Secure the mounting to the bodywork. Tighten the screws. Tighten to **24 Nm (18 lbf. ft.)** .

Fig. 25: View Of Pen Mark Where The Mounting Eyelet Is To Go Through The Carpet
Courtesy of VOLVO CARS CORPORATION

- Fold back the carpet under the mounting. Using a pen, mark where the mounting eyelet is to go through the carpet.

Fig. 26: View Of Cut In The Carpet Directly In Front Of The Marking
Courtesy of VOLVO CARS CORPORATION

- Use a carpet knife. Make a cut in the carpet directly in front of the marking. Make the cut as wide as the mounting eyelet.

Fig. 27: Carpet Back Into Place
Courtesy of VOLVO CARS CORPORATION

- Fold the carpet back into place
- Reinstall the right-hand side panel on the center console.

ISOFIX GUIDE (2003-2011)

ISOFIX GUIDE

PREPARATION

Fig. 28: View Of Isofix Guide
Courtesy of VOLVO CARS CORPORATION

- Bend up the corner (1) with the child seat marking
- Fit the Isofix guide (2) over the brace so that it "snaps into place". The slanted side of the Isofix guide should be up.

INSTALL

- Repeat the same steps on the other side.

NOTE: The Isofix guide should be removed when not in use.

LOAD COMPARTMENT DIVIDER (2003-2011)

CARGO COMPARTMENT WALL

Fig. 29: View Of Cargo Compartment Wall Measurement

Courtesy of VOLVO CARS CORPORATION

- Before installing check the measurement at point A = 410 mm. Adjust as necessary.

Fig. 30: View Of Cargo Compartment Wall Support Plate
Courtesy of VOLVO CARS CORPORATION

- Screw in the support plate (1).
- Install the lower bracket (2) as illustrated.

Fig. 31: View Of Cargo Compartment Wall
Courtesy of VOLVO CARS CORPORATION

- Position the cargo compartment wall with the clamps into the car.
- Open the upper clamp and affix it loosely on the top bar of the safety grille.
- Open the lower clamp and affix it as illustrated. Tighten the clamps only exactly as much as necessary to grip the grille, do not tighten them yet.

Fig. 32: View Of Cargo Compartment Wall Support Plate
Courtesy of VOLVO CARS CORPORATION

- Adjust so that the cargo compartment wall is vertical and in the center of the cargo compartment.
- Screw up the support plate (1) so that it is in contact with the headlining panel. The support plate must be parallel with the roof panel.
- Screw down the rear support foot (2) so that the cargo compartment wall is tensioned.
- Screw down the front support foot (3) so that the cargo compartment wall stands in a straight, vertical position.

Fig. 33: Identifying Cargo Compartment Wall Knobs
Courtesy of VOLVO CARS CORPORATION

- Tighten the knobs (1) and (2).
- Check that the cargo compartment wall does not make contact with the tailgate when it closes.

LUGGAGE COMPARTMENT NET (2003-2011)

CARGO COMPARTMENT NET

REMOVE

Fig. 34: Remove The Locking Device From The Cargo Compartment Net
Courtesy of VOLVO CARS CORPORATION

- Remove the locking device from the cargo compartment net by unscrewing the knob and pulling it off.

Fig. 35: Drilled Out Holes In Backrest Disc Through Existing Cargo Compartment Net Holes
Courtesy of VOLVO CARS CORPORATION

- Lift in the cargo compartment net through the tailgate. Hang it on the backrest disc as illustrated. Check that the net is horizontal
- Drill out the holes in the backrest disc through the existing holes in the cargo compartment net. Use a 7 mm (9/32") diameter drill bit
- Remove any meat shavings.

INSTALL

Fig. 36: View Of Locating Pins On The Striker Plate
Courtesy of VOLVO CARS CORPORATION

- Take the striker plate and insert it from the front in the hole where it was disconnected
- Insert the locating pins on the striker plate in the newly drilled holes. Take the knob and tighten the striker plate against the backrest disc.

NET POCKET, CARGO COMPARTMENT (5 SEAT) (2003-2008)

NET POCKET, CARGO COMPARTMENT

PREPARATION

Fig. 37: View Of Drilling Holes For Securing The Net Pocket
Courtesy of VOLVO CARS CORPORATION

- Measure up for drilling holes for securing the net pocket
- Drill out the holes. Use a **3 mm (1/8")** diameter drill bit. Use a **10 mm (25/64") drill stop**

- Remove the metal shavings. Smooth out the hole edges if necessary.

Fig. 38: Identifying Rear Face Of The Net Pocket Screws And Clips
Courtesy of VOLVO CARS CORPORATION

- Take two clips, two screws and the net pocket from the kit
- Using the screws and clips, tighten the rear face of the net pocket in the newly drilled holes as illustrated.

Fig. 39: View Of Front Face Of The Net Pocket In Approximate Position
Courtesy of VOLVO CARS CORPORATION

- Take two clips from the kit. Install them on the front face of the net pocket in approximately the position shown in the illustration.

Fig. 40: Identifying Lower Clip Edge To The Floor Hatch
Courtesy of VOLVO CARS CORPORATION

- Bend in the front face of the net pocket towards the side panel
- Align the entire front face of the net pocket so that it is parallel with the edges of the panel as illustrated and the lower face so that it is against the floor hatch
- Raise the lower clip so that its lower edge is **50 mm (2")** from the floor hatch
- Ensure that the clips are against the panel. Mark the panel for drilling using an awl or scriber through the holes in the clips.

Fig. 41: View Of Drilled Holes
Courtesy of VOLVO CARS CORPORATION

- Angle out the front face of the net pocket
- Drill out the holes. Use a **3 mm (1/8")** diameter drill bit. Use a **10 mm (25/64") drill stop**
- Remove any metal shavings.

INSTALL

Fig. 42: View Of Net Pocket Screws
Courtesy of VOLVO CARS CORPORATION

- Angle the net pocket in towards the panel
- Take two screws from the kit. Tighten the net pocket and clips to the panel as illustrated.

NET POCKET, CARGO COMPARTMENT (7 SEAT) (2003-2008)

NET POCKET, CARGO COMPARTMENT (7 SEAT)

PREPARATION

Illustration A is for making holes on the left-hand side

Fig. 43: View Of Making Holes On The Left-Hand Side
Courtesy of VOLVO CARS CORPORATION

Illustration B is for making holes on the right-hand side

Fig. 44: View Of Making Holes On The Right-Hand Side
Courtesy of VOLVO CARS CORPORATION

- Mark the rear edge of the left-hand side panel for holes for the net pocket. See the illustration
- Drill out the holes. Use a **3 mm (1/8")** diameter drill bit. Use a **10 mm (25/64") drill stop**
- Remove the metal shavings. Smooth out the hole edges if necessary.

Fig. 45: View Of Cargo Compartment Clips And Screws
Courtesy of VOLVO CARS CORPORATION

- Take two clips and two screws from the kit. Tighten the clips horizontally in the newly drilled holes as illustrated.

Fig. 46: Net Pocket Clips Snapped Into Place
Courtesy of VOLVO CARS CORPORATION

- Press the shorter face of the net pocket into place in the clips so that a snap is heard.

Fig. 47: Identifying Clips In Position
Courtesy of VOLVO CARS CORPORATION

- Take two clips from the kit
- Insert the front face of the net pocket against the side panel. Ensure that the lower face is parallel with the joint between the side floor hatch and the center rear floor hatch
- Position the two clips as illustrated. Mark for drilling through the holes in the clips and in the panel using a ball tipped punch or press through using a scriber.

Fig. 48: View Of Drill Holes
Courtesy of VOLVO CARS CORPORATION

- Push the net pocket to one side
- Drill out the holes. Use a **3 mm (1/8")** diameter drill bit. Use a **10 mm (25/64") drill stop**
- Remove the metal shavings. Smooth out the hole edges if necessary.

Fig. 49: View Of Net Pocket Clips
Courtesy of VOLVO CARS CORPORATION

- Take two screws from the kit
- Slide back the front face of the net pocket. Tighten to the panel using the two clips and the screws.

NET POCKET, DASHBOARD (2003-2008)

NET POCKET, DASHBOARD

REMOVE

Fig. 50: View Of Holes Drilled
Courtesy of VOLVO CARS CORPORATION

- Place the panel reverse side up on a flat surface
- Drill out the two smallest holes marked at the lower edge of the panel using a **O 3.5 mm (9/64")** drill bit
- Then drill out the two larger holes using a **O 9.5 mm (3/8")** drill bit.

NOTE: **Drill the smaller holes in the larger markings and the larger holes in the smaller markings.**

- Drill out the marked hole on the left-hand top edge of the panel. Use a **5 mm (3/16")** diameter bit
- Remove any metal shavings and even off the hole edges.

Fig. 51: Identifying Two Lower Clips Into Net
Courtesy of VOLVO CARS CORPORATION

- Press the two lower clips into the net in the lower holes at the lower edge of the panel
- Lock the clips using two new locking washers.

HINT: Use a 10 mm socket as a counterhold when installing the locking washers.

INSTALL

Fig. 52: View Of Panel Right-Hand Screw
Courtesy of VOLVO CARS CORPORATION

- Reinstall the panel. Lightly secure the panel using the right-hand screw.

Fig. 53: View Of Right-Hand Hole In The Panel
Courtesy of VOLVO CARS CORPORATION

- Mark for drilling using a pin punch. Punch through the upper right-hand hole in the panel before drilling in point 6
- Remove the panel again.

Fig. 54: Identifying Dashboard Drill Hole
Courtesy of VOLVO CARS CORPORATION

- Drill through the dashboard. Use a **3 mm (1/8")** diameter drill bit. Use a **17 mm (43/64")** drill stop
- Remove any metal shavings.

Fig. 55: Identifying Upper Left-Hand Clip Screws
Courtesy of VOLVO CARS CORPORATION

- Reinstall the panel using the right-hand screw
- Fold-up the net pocket against the panel. Ensure that the upper left-hand clip is opposite the hole
- Take the short screw and washer from the kit. First thread the screw through the clip and then the put the washer onto the screw
- Tighten the clip and the panel
- Insert and tighten the right-hand screw through the clip and panel.

NOTE: Ensure that the net is not trapped by the clips or screws when tightening.

- Reinstall the side panel on the center console.

CAUTION: Do not store sharp or heavy items in the net pocket as this may cause injury to passengers in the event of a collision. Maximum recommended weight in the net pocket is - approximately 1 kg.

PC SUPPORT TABLE (2003-2011)

PC SUPPORT TABLE

PREPARATION

- Raise the passenger seat to its highest position.

Applies to power seats

- Cut off the tie strap at the mounting for the bracket for the fire extinguisher.

REMOVE

Applies to cars with manual seats

Fig. 56: Identifying Catches And Handle
Courtesy of VOLVO CARS CORPORATION

- Undo the catches (1) and remove the handle (2).

Fig. 57: Remove Handle By Compressing Ends
Courtesy of VOLVO CARS CORPORATION

- Remove the handle (2) by pressing the ends (1) together so that the handle releases from the mounting (3).

INSTALL

Fig. 58: Identifying Installation Of Bracket In Existing Holes In Front Of Seat Frame
Courtesy of VOLVO CARS CORPORATION

- Install the bracket (1) in the existing holes in the front of the seat frame
- Install the screws (2) and nuts (3) from the kit. Tighten to **10 Nm (8 ft. lb.)**
- Reinstall the handle (4).

Applies to cars with power seats

- Carry out the first two procedures in operation, see **INSTALL**

- Clamp the removed cable in the mounting for the bracket for the fire extinguisher.

Fig. 59: Identifying Removal Of Backing From Mounting Plate
Courtesy of VOLVO CARS CORPORATION

- Clean the center of the reverse of the computer using a mild alcohol solution
- Remove the backing (1) from the mounting plate
- Press the mounting plate into place in the center of the reverse of the computer.

NOTE: Position the plate so that all the tape on the plate secures.

Fig. 60: Identifying Rubber Feet, Channels, Holes And Backing
Courtesy of VOLVO CARS CORPORATION

- Take measurements to determine the position of the rubber feet (1) (supplied with the kit) on the bottom of the computer
- Ensure that the rubber feet are at the same level as the mounting plate. This is to ensure that the lugs on the mounting plate do not catch when the computer is placed on a flat surface

- Ensure that the measurements are accurate so that the rubber feet on the computer align in the channels (2) in the table at the same time as the lugs on the mounting plate align in the holes (3)
- After taking the measurements, clean the mounting surfaces on the computer. Remove the backing (4) on the rubber feet. Press the rubber feet into place.

Fig. 61: Align PC Table Mountings Against Seat Mounting
Courtesy of VOLVO CARS CORPORATION

- Place the PC table on the cushion on the passenger seat as illustrated
- Align the PC table mountings (1) against the seat mounting (2). Tighten the PC table using the two knobs.

Fig. 62: Identifying Long Strap Looped Around Front SIPS Pipe
Courtesy of VOLVO CARS CORPORATION

- Take the long strap (1) from the kit. Make a loop around the front SIPS pipe (2)
- Route the strap back under the seat cushion and up at the backrest
- Secure the strap in the buckle (3) and tighten fully.

Fig. 63: Identifying Red Handle Pressed In Until It Clicks And Catches Engage
Courtesy of VOLVO CARS CORPORATION

- Place the computer on the PC table so that the rubber feet enter the front-rear holes in the PC table at the same time as the lugs on the mounting plate enter the round holes in the center of the PC table
- Press in the red handle (1) until it clicks and the catches engage
- Check that the computer is secure.
- Adjust the height and position of the seat for a good working position.

PROTECTIVE GRILLE, STEEL, SECOND ROW OF SEATS (2003-2011)

CARGO COMPARTMENT SAFETY GRILLE, STEEL

NOTE: **Remove the front of the cargo compartment cover when using together with a cargo compartment safety grille. This will prevent any rattling.**

PREPARATIONS CARGO COMPARTMENT COVER

REMOVE

Fig. 64: Identifying Cargo Compartment Cover
Courtesy of VOLVO CARS CORPORATION

Applies to cars with a cargo compartment cover

- Remove the cargo compartment cover from the car
- Carefully pry out both the rubber edgings on the front short section of the cargo compartment cover. Use a small screwdriver. Remove the rubber edgings
- Remove the steel edging inside the rubber edgings (if they did not come off when the rubber edgings were removed).

Fig. 65: View Of Steel Edging Inside The Rubber Edgings
Courtesy of VOLVO CARS CORPORATION

Applies to cars with cargo compartment covers with Allen screws on the sides

- Remove the Allen screws (1.3 mm), or ordinary screws, on one edge of the front of the cargo compartment cover.

Fig. 66: Identifying Underside Cargo Compartment Screws
Courtesy of VOLVO CARS CORPORATION

Applies to cars with cargo compartment covers with screws on the underside

- Remove both the screws from the underside of the front of the cargo compartment cover.

Illustration A

Fig. 67: Identifying Cargo Compartment Rear Section
Courtesy of VOLVO CARS CORPORATION

- Pull the front section of the cargo compartment cover from the channel in the rear section and put it to one side.

Illustration B

Fig. 68: View Of Cargo Compartment Cover Without Front Section
Courtesy of VOLVO CARS CORPORATION

The cargo compartment cover without its front section will be reinstalled in point 7.

INSTALLING THE CARGO COMPARTMENT SAFETY GRILLE

Fig. 69: Identifying Mounting, Knob and Cap
Courtesy of VOLVO CARS CORPORATION

- Detach the mounting, knob and cap from each other.

Fig. 70: Installing Safety Grille Into The Corresponding Mounting
Courtesy of VOLVO CARS CORPORATION

- Lift the cargo compartment safety grille in through the tailgate or through one of the rear doors (fold down the second row of seats if using one of the rear doors)
- Insert one mounting for the cargo compartment safety grille into the corresponding mounting above the rear door behind the second row of seats
- Position the cargo compartment safety grille mounting in the front position in the other mounting
- Position the other mounting for the cargo compartment safety grille over the other rear door and move it into the front position.

Fig. 71: View Of Mounted Bracket From Underneath
Courtesy of VOLVO CARS CORPORATION

- Insert the mounting bracket from underneath through the lower mounting in the cargo compartment safety grille as illustrated. Screw on the knob
- Secure the mounting bracket hook in the load securing eyelet. Tighten the knob until the mounting bracket engages the load securing eyelet

- Repeat the operation on the other side
- Tighten both the mounting brackets alternately
- Install the protective caps on the threads above the knobs
- Reinstall the cargo compartment cover.

WARNING: Applies to cars with three rows of seats: The third row of seats must be folded down when the cargo compartment safety grille is installed. It is prohibited to sit in the cargo compartment behind a cargo compartment safety grille during a journey.

SEAT CUSHION, CARGO COMPARTMENT (2003-2008)

SEAT CUSHION, CARGO COMPARTMENT

REMOVE

Fig. 72: View Of Cushions On The Lower Tailgate
Courtesy of VOLVO CARS CORPORATION

- Unfold both the cushions
- Position the cushions on the lower tailgate
- Fasten the cushions together using the Velcro strips.

INSTALL

Fig. 73: Velcro Mounting Eyelets
Courtesy of VOLVO CARS CORPORATION

- Insert the Velcro strips on the outside of the cushions through the mounting eyelets positioned in the opening of the cargo compartment. Press the Velcro strips together.

SUNGLASSES HOLDER (2003-2011)

SUNGLASSES HOLDER

PREPARATION

NOTE: Thoroughly clean the surface where the sunglasses holder is to be positioned. Use denatured alcohol.

INSTALLATION

- Remove the backing from the sunglasses holder
- Install the sunglasses holder. Press the tape hard against the surface underneath. Hold for a moment.

NOTE: After mounting, the tape must be allowed to cure for 24 hours at a minimum of +15°C (60°F) before the sunglasses holder can be used.

USING

Fig. 74: Identifying Placement Of Sunglasses In Holder And Placement Of Glasses Using Strap
Courtesy of VOLVO CARS CORPORATION

- Place the sunglasses in the holder. Secure the glasses using the strap as illustrated.

TABLE IN THE CARGO COMPARTMENT OPENING (2003-2008)

TABLE IN THE CARGO COMPARTMENT OPENING

REMOVE

Fig. 75: Identifying Mounting Bracket Between Both Hinges
Courtesy of VOLVO CARS CORPORATION

- Open the upper and lower tailgates
- Fold up and lock the floor extension in the upright position
- Remove the two inner screws in the hinge on the lower tailgate
- Install the mounting bracket (from the kit) between both hinges. Tighten the mounting bracket using the

two screws. Tighten the screws. Tighten to **50 Nm (37 lbf. ft)** .

Fig. 76: View Of Cut Out Centre Section Of Floor Extension
Courtesy of VOLVO CARS CORPORATION

- Saw out the center of the floor extension inside the inner marking on the underneath
- Even off the edges using a file
- Remove any metal shavings.

Fig. 77: Secure Table Leg To Table Top
Courtesy of VOLVO CARS CORPORATION

- Remove the table top from the kit. Turn the table top upside down
- Take the knob and table leg from the kit. Secure the table leg to the table top using the nut in the plate profile. See the illustration. Do not tighten the knob yet.

ADJUST

Fig. 78: Identifying Table Leg Adjustment Positions
Courtesy of VOLVO CARS CORPORATION

- Adjust the position of the table leg sideways as desired. Tighten the knob.

INSTALL

Fig. 79: Identifying Locking Knobs On Lower Section
Courtesy of VOLVO CARS CORPORATION

- Ensure that both locking knobs (3) on the lower section of the table leg are unscrewed from the mounting as far as possible without the leg detaching
- Install the table on the mounting bracket, as illustrated (1). Fold out the support leg (2). Lower the table so that the support leg rests against the lower tailgate
- Lock the table using both locking knobs (3).

Fig. 80: Identifying Press The Panel (From The Kit) Over The Hole
Courtesy of VOLVO CARS CORPORATION

When the table is not being used

- Press the panel (from the kit) over the hole in the floor extension.

Fig. 81: View Of Maximum Permitted Load Of The Table
Courtesy of VOLVO CARS CORPORATION

NOTE: The maximum permitted load of the table is 12 kg.

TUNNEL CARPET (2003-2008)

TUNNEL CARPET

PREPARATION

Fig. 82: Cut Underneath Of Tunnel Carpet At Perforations For Relevant Model
Courtesy of VOLVO CARS CORPORATION

- Cut the underneath of the tunnel carpet at the perforations for the relevant model. Cut so that the model designation of the car remains along the outer edges of the tunnel carpet.

INSTALL

Fig. 83: Identifying Position Of Tunnel Carpet On Transmission Tunnel In Rear Seat Compartment
Courtesy of VOLVO CARS CORPORATION

- Position the tunnel carpet on the transmission tunnel in the rear seat compartment so that an equal amount of the tunnel carpet is positioned on each side of the tunnel
- Fold the short sides of the floor carpet upwards nearest the tunnel. Position the tunnel carpet underneath the floor carpets
- Fold back the floor carpets.

DECOR TRIM, AIR INTAKE, CHROME (2007)

DECOR STRIP, AIR INTAKE, CHROME

REMOVE

Fig. 84: View Of Removing Bumper Cover Grilles
Courtesy of VOLVO CARS CORPORATION

- Carefully remove the bumper cover grilles on both sides by carefully pulling them off using tool **part no. 9512943** .

Fig. 85: Clean The Bumper Cover
Courtesy of VOLVO CARS CORPORATION

- Clean the bumper cover where the decor strip is to be secured.

INSTALL

Fig. 86: View Of Decor Panel Into Place
Courtesy of VOLVO CARS CORPORATION

- Align the decor panel in the cut-out and press it into place. Ensure that all hooks engage.
- Repeat the operation on the other side.

DECOR PANEL, INTERIOR (2008-2011)

DECOR PANEL, INTERIOR

NOTE: **Some steps in these installation instructions are presented with illustration only.**

INSTALLING, DECOR PANEL

GLOVE BOX

Fig. 87: Identifying Glove Box Screws

Courtesy of VOLVO CARS CORPORATION

- Open the glove box hatch. Remove the two outer screws that hold the decor strip.

Fig. 88: View Of Decor Strip Removal With Weatherstrip
Courtesy of VOLVO CARS CORPORATION

- Carefully bend loose the decor strip from the glove box hatch with a weatherstrip tool. It is fastened with three clips.

INSTALL

Fig. 89: View Of Snapping In New Panel Into Place
Courtesy of VOLVO CARS CORPORATION

- Get a new panel from the kit and press it into place, instead of the removed.

Fig. 90: Identifying Glove Box Screws
Courtesy of VOLVO CARS CORPORATION

ASHTRAY

Fig. 91: Pulling Rear Tunnel Console Backwards
Courtesy of VOLVO CARS CORPORATION

- Grab the handle at the trailing edge/lower edge of the rear part of the tunnel console. Pull backwards until the locks by the sides release, and pull loose the unit backwards.

Fig. 92: Identifying Ashtray Catches
Courtesy of VOLVO CARS CORPORATION

- Open the ashtray.
- Press down the ashtray until the catches by the sides are clear from the stops in the holder.
- Pull out the ashtray more and lift it out.

Fig. 93: Unfasten The Panel's Lock Catches
Courtesy of VOLVO CARS CORPORATION

- Unfasten the panels lock catches and unhook it from the top edge on the ashtray.

Fig. 94: Identifying Ashtray's Top Edge
Courtesy of VOLVO CARS CORPORATION

- Get a new panel from the kit. Hook it on in the ashtrays top edge and press at the bottom so that the lock catches engage.

REAR, CUP HOLDER

Illustration A

Fig. 95: Identifying Cup Holder Locks
Courtesy of VOLVO CARS CORPORATION

- Pull out the cup holder. Lay the tunnel console on the side on a surface that will not cause any damage.
- Carefully bend loose the panel on both sides at the bottom so that the panels small lock catches are in the clear.

Illustration B

Fig. 96: View Of Push Panel So It Unhooks
Courtesy of VOLVO CARS CORPORATION

- Push up the panel so that it unhooks from the four attachments on the inside. New panel is included in the kit.

Fig. 97: View Of Four Attachment Catches In The Holder
Courtesy of VOLVO CARS CORPORATION

- Get a new panel from the kit. Fit the four attachment catches in the holder and press into place.

COVER, MIDDLE CONSOLE

Fig. 98: Identifying Ignition Switch Turned To Position 0
Courtesy of VOLVO CARS CORPORATION

- Turn the ignition key to position 0.

NOTE: **Wait at least three minutes before unplugging the connectors or removing other electrical equipment.**

Fig. 99: View Of Pry Off The Gear Selector Panel
Courtesy of VOLVO CARS CORPORATION

Applies to cars with automatic gearbox

- Turn the ignition key to position II.

Applies to all models

- Move the gear selector lever to its rearmost position.

- Use a weatherstrip and pry off the gear selector panel at the rear edge.

Fig. 100: Pressing In Catches And Removing Panel
Courtesy of VOLVO CARS CORPORATION

- Press in the catches and remove the panel.

Fig. 101: Identifying Pen Box From The Panel
Courtesy of VOLVO CARS CORPORATION

- Remove the pen box from the panel.
- Place the panel aside, new is included in the kit.

Fig. 102: Press The Pen Box Into Place
Courtesy of VOLVO CARS CORPORATION

- Get a new panel from the kit.
- Press the pen box into place.

Fig. 103: View Of Small Rear Compartment In The Tunnel Console
Courtesy of VOLVO CARS CORPORATION

- Carefully bend loose the small rear compartment in the tunnel console with a weatherstrip tool.

Fig. 104: Identifying Tunnel Console Frame Screws
Courtesy of VOLVO CARS CORPORATION

- Remove the six screws in the frame for the tunnel console.
- Lift away the frame.

Fig. 105: Identifying Attachment Catches
Courtesy of VOLVO CARS CORPORATION

- Place the frame upside down on a surface that will not cause any damage.
- Move the attachment catches to the side and press them out through the bottom.

Fig. 106: Identifying Open Cover And Pulled Up Insert
Courtesy of VOLVO CARS CORPORATION

- Open the cover and pull up the insert.

Fig. 107: View Of Cover's Middle Attachment Clips
Courtesy of VOLVO CARS CORPORATION

- Press together the covers middle attachment clips with spring and carefully press it out.

Fig. 108: Identifying Middle Attachment Arm
Courtesy of VOLVO CARS CORPORATION

- Fold the arm forward so that it moves from the middle attachment.

Fig. 109: View Of Cover's Attachment Clips
Courtesy of VOLVO CARS CORPORATION

- Press together the covers attachment clips on both sides and press them.

Illustration A

Fig. 110: Identifying Covers Attachment Arms
Courtesy of VOLVO CARS CORPORATION

- Bend out the covers attachment arms from the holes in the sides. First bend up the covers left attachment.

Illustration B

Fig. 111: Identifying Attachment Cover Gear Clearance
Courtesy of VOLVO CARS CORPORATION

- Pull away the covers middle attachment so that it is clear of the gear.
- Lift out the cover. New cover is included in the kit.

Illustration A

Fig. 112: Identifying New Cover From Kit
Courtesy of VOLVO CARS CORPORATION

- Get a new cover from the kit and install.

Illustration B

Fig. 113: View Of Correct Gear Position
Courtesy of VOLVO CARS CORPORATION

- Make sure that the gear ends up correctly in the covers rack.

INSTALL

Fig. 114: Identifying Clips Beveled Side Up
Courtesy of VOLVO CARS CORPORATION

- Press the clips into place on both sides. Make sure that the clips bevelled part faces up.

Fig. 115: View Of Spring's Arm Against The Cover
Courtesy of VOLVO CARS CORPORATION

- Check that the internal catch on the spring is attached in the clip.
- Align the springs arm against the cover and install the clip (1) with the spring. The catches (2) on the clip shall be placed vertically.

Fig. 116: View Of Attachment Under The Clip
Courtesy of VOLVO CARS CORPORATION

- Move the springs arm backwards so that the catch engages in the attachment under the clip.

Fig. 117: Identifying Arm Forward Mechanism
Courtesy of VOLVO CARS CORPORATION

- Move the arm forward for the mechanism.
- Check the function of the cover.

Fig. 118: Pressing Cup Holder Into Place
Courtesy of VOLVO CARS CORPORATION

- Press the cup holder into place and make sure that the clips engage.

Fig. 119: Identifying Frame Screws
Courtesy of VOLVO CARS CORPORATION

Fig. 120: Installing Small Rear Compartment
Courtesy of VOLVO CARS CORPORATION

Fig. 121: Pressing In Catches And Removing Panel
Courtesy of VOLVO CARS CORPORATION

- Get the new panel and press into place in the gear lever's holder. Make sure that the catches engage.

Fig. 122: Installing Gear Selector Panel

Courtesy of VOLVO CARS CORPORATION

HOME LINK (2006-2010)

HOME LINK

REMOVE

Fig. 124: Identifying Sun Visor
Courtesy of VOLVO CARS CORPORATION

- Fold the sun visor down.

Fig. 125: Unhook Sun Visor
Courtesy of VOLVO CARS CORPORATION

- Unhook the sun visor from its mounting.

Fig. 126: Identifying Sun Visor Cover
Courtesy of VOLVO CARS CORPORATION

- Remove the cover.

Fig. 127: Identifying Sun Visor Cover Screws
Courtesy of VOLVO CARS CORPORATION

- Remove the screws.

Fig. 128: View Of Pulled Down Sun Visor
Courtesy of VOLVO CARS CORPORATION

- Press the catches in and pull the sun visor down.

INSTALL

Fig. 129: Identifying Sun Visor Connector
Courtesy of VOLVO CARS CORPORATION

- Unplug the connector.
- Take the new sun visor from the kit and install in reverse order.

NOTE: Take care not to trap the cable during installation.

Tightening torque M6 screws: **10 Nm (7.3 Ibf. ft)** .

MIRRORS, AUTODIM (2009-2011)

MIRRORS, AUTODIM

REMOVE

Fig. 130: Identifying VIDA (Service Information) To Program Software
Courtesy of VOLVO CARS CORPORATION

- Data must be read from the Upper electronic module (UEM) before replacing the inner rear view mirror. After replacement the data must be programmed into the new control module. The programmed data is read via VIDA vehicle communication.

NOTE: **First when the new inner rear view mirror has been installed in the vehicle can the new software be ordered. When ordering VIDA will read the identity of the new control module, which is essential to order the right software.**

Fig. 131: Identifying Ignition Switch Turned To Position 0
Courtesy of VOLVO CARS CORPORATION

IMPORTANT: Wait at least three minutes before disassembling the connector or removing other electrical equipment.

Fig. 132: Identifying Fold Down Cover
Courtesy of VOLVO CARS CORPORATION

- Fold down the cover.

Fig. 133: Identifying Front Edge Of Panel Catches
Courtesy of VOLVO CARS CORPORATION

- Release the catches. Pull down the front edge of the panel and then pull it off by its rear edge.

Fig. 134: View Of Mirror Panel
Courtesy of VOLVO CARS CORPORATION

Fig. 135: View Of Mirror Catch
Courtesy of VOLVO CARS CORPORATION

Fig. 136: Unplugging Connector
Courtesy of VOLVO CARS CORPORATION

1. Press in the connector's catches.
2. Unplug the connector.

Fig. 137: Identifying Mirror Screws
Courtesy of VOLVO CARS CORPORATION

Fig. 138: Identifying Interior Lighting Housing Catches
Courtesy of VOLVO CARS CORPORATION

- Release the catches and carefully pull the interior lighting downwards and let it hang from its wires.

Applies to cars with telephone

Fig. 142: Applies To Cars Without Telephone (2 of 2)
Courtesy of VOLVO CARS CORPORATION

INSTALL

Fig. 143: Identifying VIDA (Service Information) To Program Software
Courtesy of VOLVO CARS CORPORATION

Applies to all models

- Install the new inner rear view mirror in the reverse order. Tightening torque M6 bolts: **10 Nm (7.3 lbf. ft)** .
    - Repair
    - Clean, check and adjust.
    - 8 Body and interior
    - 88 Interior equipment
    - 882 Interior equipment

    - Interior equipment
    - Compass calibration
- Download the software for the accessory's function following the service information in VIDA (Volvo scan tool).
    - Repair
    - Clean, check and adjust.
    - 8 Body and interior
    - 88 Interior equipment
    - 882 Interior equipment
    - Interior equipment
    - Compass calibration
- Calibrate the compass. Information can be found in VIDA under:
    - Repair
    - Clean, check and adjust.
    - 8 Body and interior
    - 88 Interior equipment
    - 882 Interior equipment
    - Interior equipment
    - Compass calibration

ACCESSORIES AND BODY, CAB

Interior Equipment - Removal, Replacement And Installation

DASHBOARD AND RADIO PANEL (2003-2011)

DASHBOARD, REPLACING

The illustrations in this service information are used for different model years and / or models. Some variation may occur. However, the essential information in the illustrations is always correct.

PREPARATIONS

Move the seats back.

Fig. 1: Disconnecting Battery Lead
Courtesy of VOLVO CARS CORPORATION

Remove the battery lead. See **BATTERY, DISCONNECTING** .

REMOVING THE DASHBOARD

Fig. 2: End Covers
Courtesy of VOLVO CARS CORPORATION

Remove:

- The A-post panels. See **PANEL A-POST, REPLACING**
- the end covers on both sides.

- the soundproofing panels. See **SOUNDPROOFING PANEL, REPLACING**
- the courtesy lighting. See **COURTESY LIGHTING, FRONT, REPLACING**
- the on-board diagnostic (OBD) connector
- the steering wheel. See **STEERING WHEEL, REPLACING**
- the combined instrument panel. See **DRIVER INFORMATION MODULE (DIM), REPLACING**
- gear selector assembly and steering wheel module (SWM)
- the center console. See **CENTER CONSOLE, REPLACING**
- the dashboard environment panel. See **CLIMATE CONTROL MODULE (CCM), REPLACING**
- the bracket for the RTI (road traffic information) / loudspeaker. See **CENTRAL LOUDSPEAKER, REPLACING**
- the connector for the hazard warning signal flasher.

Fig. 3: Disconnecting Connector And Removing Sun Sensor
Courtesy of VOLVO CARS CORPORATION

Lift up the sun sensor.

Disconnect the connector.

Fig. 4: Identifying Parking Brake Cable And Release Handle
Courtesy of VOLVO CARS CORPORATION

Unhook the cable for the parking brake at the cable terminal by the release handle.

Fig. 5: Disconnecting Mechanical Cable For Gear Lever Lock To Facilitate Removing Dashboard
Courtesy of VOLVO CARS CORPORATION

Disconnect the cable for the gear selector lever lock.

Fig. 6: Identifying Gear Selector Assembly Screws
Courtesy of VOLVO CARS CORPORATION

Detach the gear selector assembly (four screws). Turn the gear selector assembly a quarter turn with the control downwards towards the driver's seat.

Fig. 7: Identifying Passenger Airbag Module And Screws
Courtesy of VOLVO CARS CORPORATION

Remove:

- the glove compartment. See **GLOVE COMPARTMENT, REPLACING**
- the connector for the passenger airbag module.

Remove the lower mounting for the passenger airbag module (SRS).

Remove the 2 screws.

Fig. 8: Locating Dashboard Screws
Courtesy of VOLVO CARS CORPORATION

Remove the 9 screws.

Lift out dashboard.

Fig. 9: Identifying Dashboard And Screws
Courtesy of VOLVO CARS CORPORATION

INSTALLING THE DASHBOARD

NOTE: For tightening torques, see TIGHTENING TORQUE .

Lift the dashboard.

Pull the connector for the sun sensor out through the hole in the dashboard.

NOTE: Check that no wiring is trapped at the cable ducts.

Install:

- the dashboard
- the 9 M6 screws. Tighten
- the lower mounting for the passenger airbag module
- the 2 M6 screws. Tighten
- the sun sensor
- the connector for the hazard warning signal flasher
- the cable for the parking brake. Hook the cable into place at the release handle

- the on-board diagnostic (OBD) connector
- the combined instrument panel. See **DRIVER INFORMATION MODULE (DIM), REPLACING**
- gear selector assembly and steering wheel module (SWM)
- the steering wheel. See **STEERING WHEEL, REPLACING**
- the bracket for the RTI (road traffic information) / loudspeaker. See **CENTRAL LOUDSPEAKER, REPLACING**
- the dashboard environment panel. See **CLIMATE CONTROL MODULE (CCM), REPLACING**
- the gear selector assembly
- the 4 M8 screws. Tighten
- the mechanical cable for the gear selector lever knob
- the center console. See **CENTER CONSOLE, REPLACING**
- the courtesy lighting. See **COURTESY LIGHTING, FRONT, REPLACING**
- the end covers on both sides
- The A-post panels. See **PANEL A-POST, REPLACING** .

FINISHING

Check the SRS (supplemental restraint system). See **SUPPLEMENTARY RESTRAINT SYSTEM (SRS), INSPECTION** .

REPLACING THE STEERING COLUMN COVERS

REMOVING STEERING COLUMN COVERS

Fig. 10: Identifying Steering Column Covers Removal
Courtesy of VOLVO CARS CORPORATION

Remove three screws.

Pull the steering wheel as far out as possible.

Remove the clip mounting between the covers.

Remove the lower steering column cover.

Remove the seal for the clip mounting at the dashboard.

Remove the upper steering column cover.

INSTALLING STEERING COLUMN COVERS

Install:

- the lower cover for the steering column. Secure the seals for the switches
- the three screws.

Press the seal in towards the dashboard in the upper steering column cover.

Press the upper cover into place in the upper cover.

NOTE: **Check that the seals for the switches are positioned correctly throughout the operation.**

INTERIOR EQUIPMENT (2003-2011)

CENTER CONSOLE, REPLACING

The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.

REMOVING CENTER TUNNEL CONSOLE

Fig. 11: Identifying Center Tunnel Console Removal
Courtesy of VOLVO CARS CORPORATION

Remove:

- the arm rest at the center console according to the following three alternatives:

Fig. 12: Identifying Handle And Screws
Courtesy of VOLVO CARS CORPORATION

- **Alt 1** Release handle at the arm rest's lower rear edge, pull backwards.
- **Alt 2** Remove the 2 x screws (1). Press in the catches (2), pull backwards.
- **Alt 3** Remove the 2 x covers (2). Remove the 2 x screws (1), pull backwards.

Fig. 13: Identifying Cover Removal
Courtesy of VOLVO CARS CORPORATION

- the cover.

Fig. 14: Detaching Panel At Gear Selector Lever
Courtesy of VOLVO CARS CORPORATION

- the gear shift selector panel.

Press the frame out of the gear shift selector panel.

Fig. 15: Identifying Removal Of Center Console Side Panels
Courtesy of VOLVO CARS CORPORATION

Remove:

- the side panels, left and right.

Fig. 16: Identifying Center Console Removal
Courtesy of VOLVO CARS CORPORATION

- the connectors from the cable holder
- the 6 screws.

Lift out the center tunnel console.

INSTALLING THE CENTER TUNNEL CONSOLE

Install:

- the connectors
- the center tunnel console.

NOTE: Ensure that the center tunnel console is correctly positioned in relation to the guide for the dashboard.

Install:

- the 6 screws. Tighten
- the frame for the gear shift selector panel

- the gear shift selector panel
- the cover.
- the armrest at the center tunnel console.

COOL BOX/ARMREST COMPONENTS, REPLACING

see **COOL BOX/ARMREST COMPONENTS, REPLACING**

CUP HOLDER REPAIR KIT

NOTE: Some variation may occur. However, the essential information in the illustrations is always correct.

PREPARATION

Fig. 17: Cup Holder Preparation (1 of 5)
Courtesy of VOLVO CARS CORPORATION

Fig. 18: Cup Holder Preparation (2 of 5)
Courtesy of VOLVO CARS CORPORATION

Fig. 19: Cup Holder Preparation (3 of 5)
Courtesy of VOLVO CARS CORPORATION

Fig. 20: Cup Holder Preparation (4 of 5)
Courtesy of VOLVO CARS CORPORATION

Fig. 21: Cup Holder Preparation (5 of 5)
Courtesy of VOLVO CARS CORPORATION

INSTALLATION

Fig. 22: Cup Holder Repair (1 of 9)
Courtesy of VOLVO CARS CORPORATION

Fig. 23: Cup Holder Repair (2 of 9)
Courtesy of VOLVO CARS CORPORATION

Courtesy of VOLVO CARS CORPORATION

Fig. 26: Cup Holder Repair (5 of 9)
Courtesy of VOLVO CARS CORPORATION

Fig. 27: Cup Holder Repair (6 of 9)
Courtesy of VOLVO CARS CORPORATION

Fig. 28: Cup Holder Repair (7 of 9)
Courtesy of VOLVO CARS CORPORATION

Fig. 29: Cup Holder Repair (8 of 9)
Courtesy of VOLVO CARS CORPORATION

Fig. 30: Cup Holder Repair (9 of 9)
Courtesy of VOLVO CARS CORPORATION

GLOVE COMPARTMENT, REPLACING

As the illustrations in this service information are used for different model years and / or models, some variation may occur. However, the essential information in the illustrations is always correct.

REMOVING THE GLOVE COMPARTMENT

Fig. 31: Identifying Glove Compartment Screws
Courtesy of VOLVO CARS CORPORATION

Remove:

- the soundproofing panel and the side panel. See **SOUNDPROOFING PANEL, REPLACING**
- the 9 screws
- the glove compartment
- one connector.

INSTALLING GLOVE COMPARTMENT

Install:

- the connector
- the glove compartment
- the 9 screws. Tighten
- the soundproofing panel and the side panel. See **SOUNDPROOFING PANEL, REPLACING**

SUN VISOR, REPLACING

As the illustrations in this service information are used for different model years and / or models, some variation

may occur. However, the essential information in the illustrations is always correct.

REMOVING THE SUN VISOR

Fig. 32: Removing Sun Visor
Courtesy of VOLVO CARS CORPORATION

Remove:

- the panel (2)
- the 2 screws (3).

Turn the sun visor towards the side window.

Press the catches at the mounting outwards.

Pull the sun visor straight downwards.

Disconnect and disassemble the connector.

REMOVING THE SNAP FASTENER

Open the cover.

Press in the catch.

Fold the mounting downwards.

Pull the mounting (1) back into the car at an angle.

INSTALLING THE SUN VISOR

NOTE: For tightening torques, see TIGHTENING TORQUE .

Install:

- the connector
- the mounting for the sun visor
- the 2 M6 screws. Tighten
- the cover.

INSTALLING THE SNAP FASTENER

Install the snap fastener.

Close the cover.

SEAT BELTS AND OTHER RETENTION SYSTEMS (2003-2004)

AIRBAG DRIVER'S SIDE (SRS), REPLACE

NOTE: The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.

PREPARATORY WORK

REMOVING THE BATTERY LEAD AND IMPORTANT INFORMATION

Fig. 33: Disconnecting Battery Negative Cable
Courtesy of VOLVO CARS CORPORATION

Ignition off.

Disconnect the battery negative cable. See: **BATTERY, DISCONNECTING** .

WARNING: **For information about the handling and storage of pyrotechnical SRS components, see: HANDLING NON-DEPLOYED SRS-COMPONENTS .**

NOTE: **Replace the decals for the safety equipment. See: DECALS FOR SAFETY EQUIPMENT .**

WARNING: **Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed pyrotechnical SRS component. There is a risk of the seat belt tensioner deploying.**

WARNING: **Pyrotechnical SRS components must never be taken apart, repaired or transferred to another vehicle.**

REMOVAL

REMOVING DRIVER'S AIRBAG (SRS)

Fig. 34: Identifying Steering Wheel Turned A 1/4 Turn To Access Two Holes On Back
Courtesy of VOLVO CARS CORPORATION

Ignition in position II.

Turn the steering wheel a 1/4 turn so that the two holes on the rear of the steering wheel are accessible.

Fig. 35: Identifying Screwdriver Inserted In Back Of Steering Wheel & Locating End Of Locking Spring

Courtesy of VOLVO CARS CORPORATION

Insert a screwdriver in the holes on the reverse of the steering wheel. The screwdriver must be at a right-angle to the rear surface of the steering wheel.

Place the screwdriver point against the top of the spring clip as illustrated.

Pry the screwdriver up against the upper edge of the hole (2) so that the point of the screwdriver presses down the catch (1) until the catch releases.

Turn the steering wheel a 1/2 turn in the opposite direction. Repeat the process on the other side.

Turn the steering wheel to the neutral position.

Fold out the airbag.

Fig. 36: Identifying Airbag Removal
Courtesy of VOLVO CARS CORPORATION

Disconnect the 2 connectors (2) (there may be more or less) for the SRS ignition cables for the airbag.

Remove the airbag.

ADJUSTMENT

ADJUSTING THE STEERING WHEEL

Fig. 37: Breaking Off L Shaped Plastic Bracket
Courtesy of VOLVO CARS CORPORATION

Break off the L shaped plastic bracket.

NOTE: Ensure that the broken piece does not remain in the steering wheel.

Carefully bend the cable harness down

Smooth off the break surface on the steering wheel using a fine file or similar.

Fig. 38: Identifying Tape Around Cable Harness Removal
Courtesy of VOLVO CARS CORPORATION

Remove the tape around the cable harness.

Fig. 39: Identifying Cable Harness Spread Out As Flat As Possible
Courtesy of VOLVO CARS CORPORATION

Spread the cable harness out as flat as possible.

Apply tape, part no. 9511 097.

Fig. 40: Bending Up Outer Surround Slightly
Courtesy of VOLVO CARS CORPORATION

Bend up the outer surround slightly.

Fig. 41: Bending One Of Tape Ends In Between Outer And Inner Surround
Courtesy of VOLVO CARS CORPORATION

Bend one of the tape ends in between the outer and inner surround.

Carry out the same with the other tape end so that the tape overlaps on top.

INSTALLATION

INSTALLING DRIVER'S AIRBAG (SRS)

NOTE: For airbags (replacement part) supplied without keypads, for Audio, RTI and cruise control for example, an upgrade kit must be ordered.

Install the 2 connectors (there may be more or fewer).

Press the airbag into place.

CAUTION: Make sure that the wiring is not trapped during installation.

Carry out an inspection as described in, see **SUPPLEMENTARY RESTRAINT SYSTEM (SRS), INSPECTION** .

AIRBAG MODULE SEAT (SIPS), REPLACING

NOTE: The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.

PREPARATIONS

Lean the backrest on the seat forwards. Applies only to power seats.

Fig. 42: Disconnecting Battery Lead
Courtesy of VOLVO CARS CORPORATION

Remove the battery lead. See **BATTERY, DISCONNECTING** .

For more information about storing airbags, see **HANDLING NON-DEPLOYED SRS-COMPONENTS** .

To prevent electric static discharge problems:

When removing a seat with a seat airbag module (SIPS) from the vehicle, the seat must be grounded. This is due to the danger of static electricity.

Detach the chair from its screwed joint. Do **not** lift the seat out of the vehicle yet.

Strip a long cable at both ends. Secure one end to the rear mounting on the chair. Secure the other end in the vehicle or in the car hoist.

REMOVING SEAT AIRBAG MODULES (SIPS)

Remove the seat from the vehicle. See **REMOVING THE FRONT SEAT** (-2004) or **FRONT SEAT, REPLACING** (2005-).

Release the tension in the lumbar support.

Remove:

- the lumbar support knob. See **LUMBAR SUPPORT BACKREST CUSHION, REPLACING** (-2004) or **LUMBAR SUPPORT BACKREST CUSHION, REPLACING** (2005-)
- the side piece by pulling it straight out
- the backrest adjustment knob. This applies only to manual seats
- the 5 half moon clips from the bottom of the backrest.

Remove the upholstery up to the first lateral channel. There are 2 half moon clips on each front-rear channel.

Remove 3 half moon clips from the first lateral channel.

Fig. 43: Five Half Moon Clips At Bottom Edge Of Backrest
Courtesy of VOLVO CARS CORPORATION

Remove another half moon clip from each side of the front-rear channels up to the upper front-rear channel.

Fig. 44: Identifying Spring
Courtesy of VOLVO CARS CORPORATION

Remove the 2 elastic attachments on the inside/reverse of the backrest.

Pull up the backrest upholstery.

Bend out and expose the protective pad on the side where the airbag is located.

Fig. 45: Identifying Removal Of Airbag Screws On Inside Of Backrest Frame
Courtesy of VOLVO CARS CORPORATION

Remove the 2 screws holding the airbag to the inside of the backrest frame.

Pull the airbag downwards. Fold the airbag slightly forward.

Remove the airbag.

Fig. 46: Cable Tie
Courtesy of VOLVO CARS CORPORATION

Cut the tie strap.

Fig. 47: 3 Half Moon Clips From Rear Edge Of Underside
Courtesy of VOLVO CARS CORPORATION

Cut off the 2 tie straps.

Release the cable harness.

Replace the airbag.

INSTALLING SEAT AIRBAG MODULES (SIPS)

NOTE: For tightening torques, see TIGHTENING TORQUE .

Fig. 48: Identifying Cable Harness
Courtesy of VOLVO CARS CORPORATION

Install the cable harness as illustrated.

Fig. 49: Ensuring That There Is Sufficient Slack In Cable Harness Between Ignition Cable Connector And First Tie Strap
Courtesy of VOLVO CARS CORPORATION

Ensure that there is sufficient slack in the cable harness between the ignition cable connector and the first tie strap (1).

Alternative 1 (vehicles without protective sheath on the ignition cable)

Install the other tie strap approximately 40 mm below the black mark (2) on the ignition cable.

Fig. 50: Identifying Second Tie Strap At Light Mark On Protective Sheath
Courtesy of VOLVO CARS CORPORATION

Alternative 2 (vehicles with protective sheath on the ignition cable)

Install the second tie strap at the light mark (1) on the protective sheath.

Install:

- the third tie strap under the seat cushion
- the airbag
- the 2 M5 screws. Tighten
- the protective pad
- the 2 elastic attachments on the inside/reverse of the backrest.

Pull down the backrest cushion upholstery so that the half moon clips can be installed.

Install:

- the half moon clips, one on each side, in the front-rear channel down to the first lateral channel
- 3 half moon clips in the lateral channel
- 2 half moon clips per front-rear channel down to the base of the backrest

- 5 half moon clips in the underside of the backrest
- the backrest adjustment knob. This applies only to manual seats
- the side piece by pressing it straight in
- the lumbar support knob. See **LUMBAR SUPPORT BACKREST CUSHION, REPLACING** (-2004) or **LUMBAR SUPPORT BACKREST CUSHION, REPLACING** (2005-).

Reinstall the seat in the vehicle. See **INSTALLING THE FRONT SEAT** (-2004) or **FRONT SEAT, REPLACING** (2005-).

Re-tension the lumbar support.

Carry out an inspection. See **SUPPLEMENTARY RESTRAINT SYSTEM (SRS), INSPECTION** .

AIRBAG PASSENGER (SRS), REPLACING

NOTE: The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.

PREPARATORY WORK

REMOVING THE BATTERY LEAD AND IMPORTANT INFORMATION

Fig. 51: Disconnecting Battery Negative Cable
Courtesy of VOLVO CARS CORPORATION

Ignition off.

Disconnect the battery negative lead. See: **BATTERY, DISCONNECTING** .

WARNING: **For information about the handling and storage of pyrotechnical SRS components, see: HANDLING NON-DEPLOYED SRS-COMPONENTS .**

NOTE: **Replace the decals for the safety equipment. See: DECALS FOR SAFETY EQUIPMENT .**

WARNING: **Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed pyrotechnical SRS component. There is a risk of the seat belt tensioner deploying.**

WARNING: **Pyrotechnical SRS components must never be taken apart, repaired or transferred to another vehicle.**

REMOVAL

REMOVING THE PASSENGER SIDE AIRBAG (SRS)

Fig. 52: End Covers
Courtesy of VOLVO CARS CORPORATION

Remove:

- the glove compartment. See: **GLOVE COMPARTMENT, REPLACING**
- the end cover on the passenger side.

Fig. 53: Identifying Dashboard And Screws
Courtesy of VOLVO CARS CORPORATION

Slacken off both the outer screws for the dashboard.

Fig. 54: Identifying Passenger Airbag Module And Screws
Courtesy of VOLVO CARS CORPORATION

Disconnect the connector for the SRS passenger airbag.

NOTE: The connector is between the screws for the lower mounting for the airbag.

Disconnect the lower mounting for the airbag.

Remove the 2 screws.

Fig. 55: Identifying Nuts On Airbag
Courtesy of VOLVO CARS CORPORATION

Remove the 6 nuts.

Angle and lift out the airbag.

HINT: Carefully pull the corner of the dashboard on the passenger side to make it easier to lift the airbag out.

INSTALLATION

INSTALLING THE PASSENGER SIDE AIRBAG (SRS)

Fig. 56: Identifying Nuts On Airbag
Courtesy of VOLVO CARS CORPORATION

Install:

- the airbag
- the 6 nuts. Tighten
- airbag, lower mounting
- the 2 M6 screws. Tighten
- the connector to the airbag
- the outer screws for the dashboard
- the 2 M6 screws. Tighten
- the end cover on the passenger side
- the glove compartment. See: **GLOVE COMPARTMENT, REPLACING**
- the battery lead.

Carry out an inspection. See: **SUPPLEMENTARY RESTRAINT SYSTEM (SRS), INSPECTION** .

BUCKLE SEAT BELT FRONT, REPLACING

The illustrations in this service information are used for different model years and/or models. Some variation

may occur. However, the essential information in the illustrations is always correct.

PREPARATIONS

Fig. 57: Disconnecting Battery Lead
Courtesy of VOLVO CARS CORPORATION

Remove the battery lead. See **BATTERY, DISCONNECTING** .

REMOVING THE FRONT SEAT BELT BUCKLES

Fig. 58: Identifying Cover / Clip In The Panel
Courtesy of VOLVO CARS CORPORATION

Remove:

- the front seat. See **REMOVING THE FRONT SEAT** (-2004) or **FRONT SEAT, REPLACING** (2005-)
- the cover / clip in the panel.

Move the panel back and remove it.

Fig. 59: View Of Seat Belt Buckle Screw
Courtesy of VOLVO CARS CORPORATION

Remove:

- the screw
- the seat belt buckle.

INSTALLING FRONT SEAT BELT BUCKLES

NOTE: For tightening torques, see TIGHTENING TORQUE .

Install:

- the seat belt buckle

- 1 M10 screw. Tighten
- the panel
- the cover / clip
- the front seat. See **INSTALLING THE FRONT SEAT** (-2004) or **FRONT SEAT, REPLACING** (2005-)
- the battery lead. See **BATTERY, DISCONNECTING** .

BUCKLE SEAT BELT REAR, REPLACING

LOCK SEAT BELT REAR OUTER (SECOND ROW), REPLACING

As the illustrations in this service information are used for different model years and / or models, some variation may occur. However, the essential information in the illustrations is always correct.

Included in this method are the methods for the center rear seat belt buckle, see **LOCK SEAT BELT REAR CENTER (SECOND ROW), REPLACING** and the rear seat belt buckle on the third row. See **BUCKLE SEAT BELT REAR (THIRD ROW)**.

REMOVING THE OUTER REAR SEAT BELT BUCKLE (SECOND ROW)

Move the seat as far forward as possible.

Fig. 60: Identifying Seat Belt Buckle Hinge Spring Position & Screw

Courtesy of VOLVO CARS CORPORATION

Remove:

- the seat. See **REMOVING THE OUTER SEAT (SECOND ROW)**
- 1 screw.

NOTE: Note the position of the spring.

Remove the seat belt buckle.

INSTALLING THE OUTER REAR SEAT BELT BUCKLE (SECOND ROW)

Install:

- the seat belt buckle
- 1 screw. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**
- the seat. See **INSTALLING THE OUTER SEAT (SECOND ROW)** .

Check the function of the lock.

LOCK SEAT BELT REAR CENTER (SECOND ROW), REPLACING

PREPARATIONS

Remove the battery lead. See **BATTERY, DISCONNECTING** .

Angle the backrest forward.

REMOVING THE CENTER REAR SEAT BELT BUCKLE (SECOND ROW)

Fig. 61: Identifying Seat Hinge Cover Removal
Courtesy of VOLVO CARS CORPORATION

Remove the center seat. See **REMOVING THE CENTER SEAT (SECOND ROW)** .

Disconnect the connector.

Lift the seat from the car.

Remove:

- the 2 screws
- the panel at the seat belt buckle.

Fig. 62: Identifying Seat Hinge Spring & Screw
Courtesy of VOLVO CARS CORPORATION

HINT: Turn the seat upside down to access the nut.

NOTE: Note the position of the spring.

Remove:

- the screw and nut
- the seat belt buckle.

INSTALLING THE CENTER REAR SEAT BELT BUCKLE (SECOND ROW)

Install:

- the seat belt buckle
- the screw and nut. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**
- the panel at the seat belt buckle
- the 2 screws. Tighten.

Lift the seat into the car.

Install:

- the connector
- the center seat. See **INSTALLING THE CENTER SEAT (SECOND ROW)**
- the battery lead. See **BATTERY, DISCONNECTING** .

Check:

- the function of the lock
- that the spring is working.

BUCKLE SEAT BELT REAR (THIRD ROW)

REMOVING THE BUCKLE FOR THE REAR SEAT BELT (THIRD ROW)

Fig. 63: Identifying Center Storage Compartment With Two Screws
Courtesy of VOLVO CARS CORPORATION

Slide back the seat cushion.

Remove:

- the jack
- the 2 screws for the rear center tunnel console
- the center tunnel console by pulling it forwards and upwards.

- one screw and one nut
- the seat belt buckle.

INSTALLING THE BUCKLE FOR THE REAR SEAT BELT (THIRD ROW)

Install:

- the seat belt buckle
- the screw and nut. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**
- the center tunnel console
- the 2 screws. Tighten
- the jack.

COLLISION SENSOR B AND C-POST, REPLACING

As the illustrations in this service information are used for different model years and / or models, some variation may occur. However, the essential information in the illustrations is always correct.

COLLISION SENSOR B-POST, REPLACING

PREPARATIONS

Fig. 64: Disconnecting Battery Lead
Courtesy of VOLVO CARS CORPORATION

Remove the battery lead. See **BATTERY, DISCONNECTING** .

REMOVING THE COLLISION SENSOR B-POST

Fig. 65: Identifying Removal Of B-Post Panel And 2 Screws
Courtesy of VOLVO CARS CORPORATION

Remove:

- the B-post panel. See **PANEL B-POST, REPLACING**
- the connector by pressing the catch and carefully pull downwards.

NOTE: Do not pull the wiring.

- the 2 screws
- the collision sensor.

INSTALLING THE COLLISION SENSOR IN THE B-POST

Install:

- the collision sensor
- the 2 screws. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**
- the connector
- the B-post panel. See **PANEL B-POST, REPLACING** .

COLLISION SENSOR C-POST, REPLACING

PREPARATIONS

Fig. 66: Disconnecting Battery Lead
Courtesy of VOLVO CARS CORPORATION

Remove the battery lead. See **BATTERY, DISCONNECTING** .

REMOVING THE COLLISION SENSOR FROM THE C-POST

Fig. 67: Identifying Removal Of Connector And 2 Screws
Courtesy of VOLVO CARS CORPORATION

Remove:

- the side panel. See **SIDE PANEL CARGO COMPARTMENT, REPLACEMENT**
- the connector by pressing the catch and carefully pull downwards.

NOTE: Do not pull the wiring.

- the 2 screws
- the collision sensor.

INSTALLING THE COLLISION SENSOR IN THE C-POST

Install:

- the collision sensor
- the 2 screws. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**
- the connector
- the side panel. See **SIDE PANEL CARGO COMPARTMENT, REPLACEMENT** .

COLLISION SENSOR FRONT, REPLACING

The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.

PREPARATIONS

Fig. 68: Disconnecting Battery Lead
Courtesy of VOLVO CARS CORPORATION

Remove the battery lead. See **BATTERY, DISCONNECTING** .

REMOVING THE FRONT COLLISION SENSOR

Fig. 69: Identifying Collision Sensor Connector And Screws
Courtesy of VOLVO CARS CORPORATION

Remove:

- the headlamp. See
- the 2 screws
- the connector.

NOTE: Do not pull on the wiring.

INSTALLING THE FRONT COLLISION SENSOR

NOTE: For tightening torques, see GENERAL TIGHTENING TORQUE .

Install:

- the headlamp. See
- the connector
- the 2 M6 screws. Tighten

CONTACT REEL, REPLACEMENT

The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.

PREPARATIONS

Fig. 70: Disconnecting Battery Lead
Courtesy of VOLVO CARS CORPORATION

Disconnect the battery lead. See **BATTERY, DISCONNECTING** .

REMOVING THE CONTACT REEL

Fig. 71: Identifying Contact Reel And Screws
Courtesy of VOLVO CARS CORPORATION

Remove:

- the steering column covers. See **REPLACING THE STEERING COLUMN COVERS**
- the steering wheel according to **STEERING WHEEL, REPLACING** .

Disconnect the left connector.

Remove:

- four screws
- the contact reel.

INSTALLING THE CONTACT REEL

NOTE: For tightening torques, see TIGHTENING TORQUE .

Install:

- the contact reel
- the 4 M5 screws. Tighten
- the connector.

Zero the contact reel. See **CONTACT REEL DRIVER AIRBAG MODULE, RESETTING** .

Install:

- the steering wheel according to **STEERING WHEEL, REPLACING**
- the steering column covers. See **REPLACING THE STEERING COLUMN COVERS**.

END MOUNTING, REPLACING

NOTE: The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.

This section contains methods for:

- the end mounting for the front seat. See: **END MOUNTING FRONT, REPLACING**
- the end mountings for the seats in the second row. See: **END MOUNTINGS REAR (SECOND ROW), REPLACING**
- the end mounting for the third row. See: **END MOUNTING REAR (THIRD ROW), REPLACING**.

END MOUNTING FRONT, REPLACING

REMOVING FRONT END MOUNTINGS

Fig. 72: Identifying Weatherstrip Tool And Seat Belt End Mounting
Courtesy of VOLVO CARS CORPORATION

Move the front seat as far forward as possible.

Remove the side panel. See: **SIDE PANEL, REPLACING** (-2004) or: **SIDE PANEL FRONT SEAT, REPLACING** (2005-).

NOTE: Use a weatherstrip tool to disconnect the seat belt from the end mounting. Carefully press the locking tab, as illustrated.

Remove the screw from the seat. Remove the end mounting.

INSTALLING FRONT END MOUNTINGS

NOTE: For tightening torques, see: TIGHTENING TORQUE .

Fig. 73: Identifying Seat Belt And End Mounting
Courtesy of VOLVO CARS CORPORATION

Install:

- the end mounting
- the M10 screw. Tighten.

Press the seat belt into the end mounting.

NOTE: **A clear click is heard when the seat belt has locked correctly with the end mounting.**

NOTE: **Also check that the seat belt has locked correctly with the end mounting by looking at the reverse of the end mounting.**

A = Correctly locked position.

B = If the lock facing does not lock correctly with the end mounting, see A, replace the end mounting with a **new** one.

NOTE: **Check that the seat belt is secure by jerking it hard in an upwards direction.**

Reinstall the side panel. See: **SIDE PANEL, REPLACING** (-2004) or: **SIDE PANEL FRONT SEAT, REPLACING** (2005-).

END MOUNTINGS REAR (SECOND ROW), REPLACING

REMOVING REAR END MOUNTINGS (SECOND ROW)

Fig. 74: Disconnecting Seat Belt From End Mounting By Pressing Locking Tab With Weatherstrip Tool
Courtesy of VOLVO CARS CORPORATION

Install the front seat and the outer seat in the second row in their forward positions.

NOTE: **Disconnect the top edge of the sill trim panel. Disconnect the seat belt from the end mounting by carefully pressing the locking tab with a weatherstrip tool, as illustrated, so that the seat belt releases from the end mounting.**

Remove the sill trim panel. See: **SILL TRIM PANEL, REPLACING**

Move any hoses for the air conditioning (A/C) system to one side.

Remove:

- the screw

- the end mounting.

INSTALLING REAR END MOUNTINGS (SECOND ROW)

NOTE: For tightening torques, see: TIGHTENING TORQUE .

Fig. 75: Identifying End Mounting And Screw
Courtesy of VOLVO CARS CORPORATION

Install:

- the end mounting
- 1 M10 screw. Tighten.

Move any hoses for the air conditioning (A/C) system back into place.

Install the sill trim panel. See: **SILL TRIM PANEL, REPLACING** .

Press the seat belt into the end mounting.

NOTE: A clear click is heard when the seat belt has locked correctly with the end mounting.

NOTE: Also check that the seat belt has locked correctly with the end mounting by looking at the reverse of the end mounting.

Fig. 76: Identifying Correct And Incorrect Positions For Lock Facing Against End Mounting
Courtesy of VOLVO CARS CORPORATION

The position of the lock facing against the end mounting, with the seat belt fully inserted, must be:

A = Correctly locked position.

B = If the lock facing does not lock correctly with the end mounting, see A, replace the end mounting with a **new** one.

NOTE: Check that the seat belt is secure by jerking it hard in an upwards direction.

END MOUNTING REAR (THIRD ROW), REPLACING

PREPARATORY WORK

HINT: The end mounting lug, positioned between the side panel and the end mounting, is difficult to access. To release the seat belt from the end mounting, unscrew the entire end mounting from the third row of seats as follows.

Fig. 77: Identifying Access Hole For End Mounting
Courtesy of VOLVO CARS CORPORATION

Slide the second row seat(s) forward and fold the backrest(s).

Slide the seat cushion(s) for the third row back.

NOTE: Check to, see if the vehicle has a half moon access hole for the screw for the end mounting (See the illustration).

REMOVING REAR END MOUNTINGS (THIRD ROW) WITHOUT ACCESS HOLE

Make a cut-out in the seat rail for the seat cushion.

Fig. 78: Identifying Dimensions For Cut-Out In Seat Cushion Rail
Courtesy of VOLVO CARS CORPORATION

Measure up the cut-out according to the following dimensions.

A=11 mm.

B=25 mm.

C=15 mm.

Fig. 79: Identifying Access Hole Milled Out Using Rotary File
Courtesy of VOLVO CARS CORPORATION

Push the carpet to one side.

Mill out the access hole. Use a rotary file.

Fig. 80: Identifying Vacuuming Of Milling Particles
Courtesy of VOLVO CARS CORPORATION

Vacuum up the metal shavings from the milling. Wipe clean the seat rail for the seat cushion.

Fold back the carpet.

REMOVING REAR END MOUNTINGS (THIRD ROW) WITH ACCESS HOLE

Fig. 81: Identifying Remove The Screw For End Mounting
Courtesy of VOLVO CARS CORPORATION

Remove the screw for the end mounting. Angle out the end mounting at the lower edge and lift straight up.

Fig. 82: Identifying Seat Belt At End Mounting
Courtesy of VOLVO CARS CORPORATION

Remove the seat belt from the end mounting.

INSTALLING REAR END MOUNTINGS (THIRD ROW)

Install the seat belt to the end mounting.

NOTE: **A clear click is heard when the seat belt has locked correctly with the end mounting.**

Fig. 83: Identifying Lower Section Of End Mounting And Groove In Seat Frame
Courtesy of VOLVO CARS CORPORATION

Install the end mounting to the seat frame (1).

NOTE: **The lower section of the end mounting must be aligned with the groove in the seat frame (2).**

Fig. 84: Identifying Seat Belt Screw
Courtesy of VOLVO CARS CORPORATION

Install 1 M10 screw. Tighten. See: **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS** .

NOTE: Check that the seat belt is secure by jerking it hard in an upwards direction.

FINISHING

Pull the seat cushion(s) for the third row forward.

IC (INFLATABLE CURTAIN) MODULE, REPLACING

As the illustrations in this service information are used for different model years and / or models, some variation may occur. However, the essential information in the illustrations is always correct.

PREPARATIONS

Fig. 85: Disconnecting Battery Lead
Courtesy of VOLVO CARS CORPORATION

Remove the battery lead. See **BATTERY, DISCONNECTING** .

For information about the inflatable curtain, see **HANDLING NON-DEPLOYED SRS-COMPONENTS** .

NOTE: When installing the inflatable curtain, part of the decal on the curtain must be ripped off and stuck on the decal in the door opening.

NOTE: There are two XC90 versions.

- **The five seat version has one inflatable curtain on each side**
- **The seven seat version has two inflatable curtains on each side.**

WARNING: Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, inflatable curtain. There is a risk of deployment.

WARNING: The inflatable curtain must never be unscrewed, repaired or moved to another vehicle.

INFLATABLE CURTAIN (FIVE SEAT VERSION), REPLACING

REMOVING INFLATABLE CURTAINS (FIVE SEAT VERSION)

Fig. 86: Identifying Inflatable Curtain Support Clips
Courtesy of VOLVO CARS CORPORATION

Remove:

- the headlining. See **HEADLINING, REPLACING**
- the connector
- the support clips from the body, (4 each side). See **SUPPORT CLIPS INFLATABLE CURTAIN (INFLATABLE CURTAIN MODULE), REPLACING**.

Fig. 87: Identifying Screw And Clips
Courtesy of VOLVO CARS CORPORATION

Remove:

- the front securing clip
- the clip at the A-post. Unhook the hook
- the screw.

Fig. 88: Locating Screws
Courtesy of VOLVO CARS CORPORATION

- the screw from the gas generator bracket. Unhook
- the screw from the eyelet mounting. Unhook.

Lift out the inflatable curtain.

INSTALLING INFLATABLE CURTAINS (FIVE SEAT VERSION)

NOTE: For tightening torques, see TIGHTENING TORQUE .

Fig. 89: Locating Screws
Courtesy of VOLVO CARS CORPORATION

Install:

- the insert on the gas generator bracket on the body side
- the 4 support clips on the body side. Press into place
- the 3 M6 screws. Tighten
- 1 M6 screw to the eyelet. Tighten.

Fig. 90: Identifying Screw And Clips
Courtesy of VOLVO CARS CORPORATION

- 1 M6 screw for the gas pipe at the A-post. Unhook the hook at the A-post
- the clip
- the front securing clip at the A-post.

CAUTION: Always replace the front securing clip with a new one.

Fig. 91: Identifying Sail Fixation
Courtesy of VOLVO CARS CORPORATION

Check:

- the function of the clip for the sail fixation so that it releases easily
- that the inflatable curtain is not trapped.

Install:

- the connector
- the headlining. See **HEADLINING, REPLACING** .

Carry out an inspection. See **SUPPLEMENTARY RESTRAINT SYSTEM (SRS), INSPECTION** .

INFLATABLE CURTAIN (SEVEN SEAT VERSION), REPLACING

REMOVING INFLATABLE CURTAINS (SEVEN SEAT VERSION)

Fig. 92: Identifying Inflatable Curtain Support Clips
Courtesy of VOLVO CARS CORPORATION

Remove:

- the headlining. See **HEADLINING, REPLACING**
- the connector
- the support clips from the body, (4 each side). See **SUPPORT CLIPS INFLATABLE CURTAIN (INFLATABLE CURTAIN MODULE), REPLACING**

Fig. 93: Identifying Screw And Clips
Courtesy of VOLVO CARS CORPORATION

- the front securing clip
- the clip at the A-post. Unhook the hook
- the screw.

Fig. 94: Identifying Screws, Nuts, And Clip For Inflatable Curtain Components
Courtesy of VOLVO CARS CORPORATION

- the screw from the bracket for the front gas generator. Unhook the screw
- the screw at the D-post
- the nuts, x2, from the bracket for the rear gas generator
- the clip from the bracket for the rear gas generator.

Lift out the inflatable curtain.

INSTALLING INFLATABLE CURTAINS (SEVEN SEAT VERSION)

NOTE: For tightening torques, see TIGHTENING TORQUE .

Fig. 95: Identifying Screws, Nuts, And Clip For Inflatable Curtain Components
Courtesy of VOLVO CARS CORPORATION

Install:

- the insert on the gas generator bracket on the body side
- the 4 support clips on the body side. Press into place
- the front gas generator with the center screw, x1 M6. Tighten
- the rear gas generator. Secure using clips
- 2 x M6 nuts. Tighten
- 1 x M6 screw at the D-post. Tighten.

Fig. 96: Identifying Screw And Clips
Courtesy of VOLVO CARS CORPORATION

- 1 M6 screw for the gas pipe the A-post. Unhook the hook at the A-post
- the clip
- the front securing clip at the A-post.

CAUTION: Always replace the front securing clip with a new one.

Fig. 97: Identifying Sail Fixation
Courtesy of VOLVO CARS CORPORATION

Check:

- the function of the clip for the sail fixation so that it releases easily
- that the inflatable curtain is not trapped.

Install:

- the connector
- the headlining. See **HEADLINING, REPLACING** .

Carry out an inspection. See **SUPPLEMENTARY RESTRAINT SYSTEM (SRS), INSPECTION** .

SEAT BELT FRONT, REPLACING

As the illustrations in this service information are used for different model years and / or models, some variation may occur. However, the essential information in the illustrations is always correct.

WARNING: **Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected non-deployed seat belt tensioner. There is a risk that the seat belt tensioner could deploy.**

WARNING: The seat belt tensioner must never be taken apart, repaired or moved to another vehicle.

PREPARATIONS

Fig. 98: Disconnecting Battery Lead
Courtesy of VOLVO CARS CORPORATION

Move the front seat as far forward as possible. Fold the backrest forward.

Disconnect the battery lead. See **BATTERY, DISCONNECTING** .

For information about handling seat belt tensioners, see **HANDLING NON-DEPLOYED SRS-COMPONENTS** .

REMOVING FRONT SEAT BELTS

Fig. 99: Identifying Front Seat Belt And Bolts
Courtesy of VOLVO CARS CORPORATION

Remove:

- the end mounting. See **END MOUNTING, REPLACING**
- the B-post panel. See **PANEL B-POST, REPLACING**
- the connector
- the three screws
- the clip for the mounting for the SRS ignition cable in the bracket
- the bracket for the seat belt and seat belt (inertia) reel.

INSTALLING FRONT SEAT BELTS

Install:

- the bracket for the seat belt
- the 3 screws. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**
- the connector
- the B-post panel. See **PANEL B-POST, REPLACING**
- the end mounting. See **END MOUNTING, REPLACING**

Check the function of the seat belt. See **SEAT BELT FUNCTION, CHECK** .

Carry out a final inspection. See **SUPPLEMENTARY RESTRAINT SYSTEM (SRS), INSPECTION** .

SEAT BELT REAR, REPLACING

As the illustrations in this service information are used for different model years and / or models, some variation may occur. However, the essential information in the illustrations is always correct.

WARNING: **Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected non-deployed seat belt tensioner. There is a risk that the seat belt tensioner could deploy.**

WARNING: **The seat belt tensioner must never be taken apart, repaired or moved to another vehicle.**

Included in this method are the methods for the center rear seat belt, see **SEAT BELT REAR CENTER (SECOND ROW), REPLACING** and the rear seat belt on the third row. See **SEAT BELT REAR (THIRD ROW), REPLACING**.

SEAT BELT REAR (SECOND ROW), REPLACING

PREPARATIONS

Fig. 100: Disconnecting Battery Lead
Courtesy of VOLVO CARS CORPORATION

Move the seat as far forward as possible. Fold the backrest forward.

Disconnect the battery lead. See **BATTERY, DISCONNECTING** .

For information about handling seat belt tensioners, see **HANDLING NON-DEPLOYED SRS-COMPONENTS** .

REMOVING THE REAR SEAT BELT (SECOND ROW)

Fig. 101: Identifying Seat Belt Assembly And Bolt
Courtesy of VOLVO CARS CORPORATION

Remove:

- the C-post panel. See **PANEL C-POST, REPLACING**
- the side panel. See **SIDE PANEL CARGO COMPARTMENT, REPLACEMENT**
- one screw from the bracket for the seat belt (inertia) reel
- the bracket for the seat belt (inertia) reel by unhooking it
- the connector
- one screw from the upper mounting
- the end mounting. See **END MOUNTING, REPLACING**.

Thread the seat belt out of the C-post panel.

INSTALLING THE REAR SEAT BELT (SECOND ROW)

NOTE: For tightening torques, see TIGHTENING TORQUE .

Install:

- the seat belt reel and bracket
- the connector
- the bracket for the seat belt (inertia) reel by hooking it into place
- 1 M10 screw. Tighten
- the upper mounting
- 1 M10 screw for the upper mounting. Tighten.

Insert the seat belt through the C-post panel.

Install:

- the end mounting. See **END MOUNTING, REPLACING**
- the side panel. See **SIDE PANEL CARGO COMPARTMENT, REPLACEMENT**
- the C-post panel. See **PANEL C-POST, REPLACING**

Check the function of the seat belt. See **SEAT BELT FUNCTION, CHECK** .

Carry out a final inspection. See **SUPPLEMENTARY RESTRAINT SYSTEM (SRS), INSPECTION** .

SEAT BELT REAR CENTER (SECOND ROW), REPLACING

PREPARATIONS

Fig. 102: Disconnecting Battery Lead
Courtesy of VOLVO CARS CORPORATION

Disconnect the battery lead. See **BATTERY, DISCONNECTING** .

REMOVING THE CENTER REAR SEAT BELT (SECOND ROW)

Disconnect the connector under the seat.

Remove the center seat. See **REMOVING THE CENTER SEAT (SECOND ROW)** . Lift the seat from the car.

Fig. 103: Folding Up Upholstery
Courtesy of VOLVO CARS CORPORATION

Remove:

- the upholstery from the backrest frame. See **UPHOLSTERY BACKREST CUSHION CENTER (SECOND ROW), REPLACING**
- the three screws.

Fig. 104: Identifying Seat Belt Assembly And Screw
Courtesy of VOLVO CARS CORPORATION

- the rear section from the backrest frame
- one screw for the end mounting
- one screw for the upper seat belt mounting
- one screw for the seat belt reel.

Disconnect the connector.

Remove the seat belt (inertia) reel.

INSTALLING THE CENTER REAR SEAT BELT (SECOND ROW)

NOTE: For tightening torques, see TIGHTENING TORQUE .

Install:

- the connector
- the seat belt reel
- 1 screw. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**
- the upper seat belt anchorage
- 1 screw. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**
- the end mounting
- 1 M10 screw. Tighten
- the rear section
- the 3 screws. Tighten
- the upholstery for the backrest frame. See **UPHOLSTERY BACKREST CUSHION CENTER (SECOND ROW), REPLACING** .

Lift the seat into the car.

Install:

- the connector under the seat
- the center seat. See **INSTALLING THE CENTER SEAT (SECOND ROW)** .

Check the function of the seat belt. See **SEAT BELT FUNCTION, CHECK** .

Carry out a final inspection. See **SUPPLEMENTARY RESTRAINT SYSTEM (SRS), INSPECTION** .

SEAT BELT REAR (THIRD ROW), REPLACING

PREPARATIONS

Fig. 105: Disconnecting Battery Lead
Courtesy of VOLVO CARS CORPORATION

Fold the backrest cushions up from the floor. Leave the seat cushions in place.

Remove the battery lead. See **BATTERY, DISCONNECTING** .

For information about handling seat belt tensioners, see **HANDLING NON-DEPLOYED SRS-COMPONENTS** .

REMOVING SEAT BELTS (THIRD ROW)

Fig. 106: Releasing Catch Using Chisel Or Screwdriver With Bent Tip
Courtesy of VOLVO CARS CORPORATION

HINT: Bend the tip of a groove-cut chisel 90°. Release the catch for the end mounting using the chisel.

Fig. 107: Identifying Floor Panel
Courtesy of VOLVO CARS CORPORATION

Remove:

- the outer load floor.

Fig. 108: Removing Side Panel Cover
Courtesy of VOLVO CARS CORPORATION

- the cover for the side panel.
- the seat belt cover in the D-post panel
- the end mounting. See **END MOUNTING, REPLACING**
- one screw from the upper seat belt anchorage
- one screw from the mounting for the seat belt (inertia) reel.

Fig. 109: Locating Seat Belt Reel
Courtesy of VOLVO CARS CORPORATION

Unhook from the seat belt reel.

Remove the connector for the SRS ignition cable.

Thread the seat belt through the hole at the D-post panel and out through the hole in the side panel.

INSTALLING REAR SEAT BELTS (THIRD ROW)

NOTE: For tightening torques, see TIGHTENING TORQUE .

Fig. 110: Locating Seat Belt Reel
Courtesy of VOLVO CARS CORPORATION

Thread the seat belt through the hole in the side post panel and out through the hole in the D-post panel.

Connect the connector to the SRS ignition cable.

Hook onto the seat belt reel.

Install:

- 1 screw for the seat belt reel. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**
- 1 M10 screw for the upper mounting. Tighten
- the end mounting. See **END MOUNTING, REPLACING**
- the seat belt cover
- the cover for the side panel
- the outer load floor.

Check the function of the seat belt. See **SEAT BELT FUNCTION, CHECK** .

Carry out a final inspection. See **SUPPLEMENTARY RESTRAINT SYSTEM (SRS), INSPECTION** .

STOP BUTTON SEAT BELT, REPLACING

As the illustrations in this service information are used for different model years and / or models, some variation may occur. However, the essential information in the illustrations is always correct.

POSITIONING THE STOP BUTTON

Fig. 111: Checking Belt Does Not Fray When Spike On Stop Is Pressed Through Belt
Courtesy of VOLVO CARS CORPORATION

This method covers all stops positioned on seat belts in the vehicle.

The stop must be positioned in the center of the belt at a distance of XXXX mm from the end mounting. See **STOP BUTTON SEAT BELT, SPECIFICATIONS** .

Check that the belt does not fray when the spike on the stop is pressed through the belt.

Thread the cover onto the stop.

Fig. 112: Checking That Belt Does Not Fray When Spike On Stop Is Pressed Through Belt
Courtesy of VOLVO CARS CORPORATION

Press the sections together as much as possible.

HINT: Hold the cover in place so that there is no gap. Use round-nosed pliers.

WARNING: **The seat belt material must not be overheated or it will melt. If this happens, the entire seat belt must be replaced.**

Fig. 113: Heating Using A Soldering Iron Or A Hot Air Gun Equipped With A Long Narrow Nozzle
Courtesy of VOLVO CARS CORPORATION

Heat using a soldering iron or a hot air gun equipped with a long narrow nozzle. Heat until the spike melts and the sections cannot be separated. Hold in place until the material has cooled down.

Check that the stop is secure and cannot be pulled off.

SUPPLEMENTAL RESTRAINT SYSTEM MODULE (SRS), REPLACING

NOTE: The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.

WARNING: The supplemental restraint system module (SRS) for the XC90 contains a new function, ROP (Roll Over Protection). This means that the control module cannot be worked on, removed or moved out of position without the power supply being switched off. Otherwise the airbags and seat belt tensioners may deploy.

PREPARATIONS

Fig. 114: Disconnecting Battery Lead
Courtesy of VOLVO CARS CORPORATION

Remove the battery cable. See **BATTERY, DISCONNECTING** .

REMOVING THE SUPPLEMENTAL RESTRAINT SYSTEM MODULE (SRS)

Fig. 115: Identifying Boot & Connector
Courtesy of VOLVO CARS CORPORATION

Remove:

- the tunnel compartment. See: **CENTER CONSOLE, REPLACING**
- the boot
- the connector

Fig. 116: 3 Control Module Screws
Courtesy of VOLVO CARS CORPORATION

- the 3 screws.

Lift out the supplemental restraint system module (SRS).

INSTALLING THE SUPPLEMENTAL RESTRAINT SYSTEM MODULE (SRS)

NOTE: For tightening torques, see: TIGHTENING TORQUE .

NOTE: Ensure that nothing is between the SRS (supplemental restraint system) module and the body panel, such as large particles of dirt or dust. This can cause over-sensitivity or poor SRS system function.

Fig. 117: Three Control Module Screws
Courtesy of VOLVO CARS CORPORATION

Install:

- the supplemental restraint system module (SRS)
- the 3 x M6 screws and tighten
- the connector.
- the boot
- the center console. See **CENTER CONSOLE, REPLACING**.

FINAL CHECK

Order the software in accordance with: 9438415 .

Program the new supplemental restraint system module (SRS).

Applies to MY 2005-

After downloading and configuring the control module the control module receives the vehicle configuration data from the central electronic module (CEM). This can take up to 15 seconds and during this time the SRS lamp flashes in the Driver information module (DIM). Downloading and configuration is complete when the SRS lamp stops flashing.

Carry out an inspection as described in, see **SUPPLEMENTARY RESTRAINT SYSTEM (SRS), INSPECTION** .

SUPPORT CLIPS INFLATABLE CURTAIN (INFLATABLE CURTAIN MODULE), REPLACING

NOTE: The illustrations in this service information are used for different model years and / or models. Some variation may occur. However, the essential information in the illustrations is always correct.

REMOVING THE INFLATABLE CURTAIN (IC MODULE) SUPPORT CLIPS

Fig. 118: Identifying Inflatable Curtain Support Clips
Courtesy of VOLVO CARS CORPORATION

Remove the cover with plug.

HINT: Use a TX10 Torx driver. Press the driver straight into the hole to release the catches on the plug.

Move the cover to one side.

Fig. 119: Identifying Weatherstrip Tool, Support Clip & Bodywork
Courtesy of VOLVO CARS CORPORATION

Angle the support clip to one side.

Insert the weatherstrip tool between the support clip and the bodywork. See the illustration.

Unclip the clip from the body. The support clips will be deformed.

NOTE: Always replace removed support clips with new ones.

When replacing the new inflatable curtain (IC module):

The support clips are pre-mounted on the new inflatable curtain.

When replacing the support clips on the existing inflatable curtain (IC module):

Remove the inflatable curtain (IC-module) from the car. See **IC (INFLATABLE CURTAIN) MODULE, REPLACING**.

Place the inflatable curtain on a level surface.

Check that the inflatable curtain is taped (white pieces of tape).

If these pieces of tape are missing, replace the inflatable curtain with a new one.

Fig. 120: Identifying Weatherstrip Tool, Support Clip & Bodywork
Courtesy of VOLVO CARS CORPORATION

NOTE: Only replace one support clip at a time.

Fig. 121: Identifying Support Clip
Courtesy of VOLVO CARS CORPORATION

Remove the support clip from the inflatable curtain.

INSTALLING THE INFLATABLE CURTAIN (IC MODULE) SUPPORT CLIPS

Fig. 122: Identifying Support Clip
Courtesy of VOLVO CARS CORPORATION

Install the new support clip on the inflatable curtain.

NOTE: Ensure that the support clip has clicked together.

Check that the hooks have locked.

Reinstall the inflatable curtain in the car. See **IC (INFLATABLE CURTAIN) MODULE, REPLACING**.

SEAT BELTS AND OTHER RETENTION SYSTEMS (2003-2011)

AIRBAG DRIVER'S SIDE (SRS), REPLACING

NOTE: The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.

NOTE: For vehicles MY -2004 see: AIRBAG DRIVER'S SIDE (SRS), REPLACE.

PREPARATORY WORK

REMOVING THE BATTERY LEAD AND IMPORTANT INFORMATION

Fig. 123: Disconnecting Battery Negative Cable
Courtesy of VOLVO CARS CORPORATION

Ignition off.

Disconnect the battery negative cable. See: **BATTERY, DISCONNECTING** .

WARNING: **For information about the handling and storage of pyrotechnical SRS components, see: HANDLING NON-DEPLOYED SRS-COMPONENTS .**

NOTE: **Replace the decals for the safety equipment. See: DECALS FOR SAFETY EQUIPMENT (2003-2006) .**

WARNING: **Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed pyrotechnical SRS component. There is a risk of the seat belt tensioner deploying.**

WARNING: **Pyrotechnical SRS components must never be taken apart, repaired or transferred to another vehicle.**

REMOVAL

REMOVING DRIVER'S AIRBAG (SRS)

Fig. 124: Identifying Steering Wheel Turned A 1/4 Turn To Access Two Holes On Back
Courtesy of VOLVO CARS CORPORATION

Ignition in position II.

Turn the steering wheel a 1/4 turn so that the two holes on the rear of the steering wheel are accessible.

Fig. 125: Identifying Screwdriver Inserted In Back Of Steering Wheel & Locating End Of Locking Spring
Courtesy of VOLVO CARS CORPORATION

Insert a screwdriver in the holes on the reverse of the steering wheel. The screwdriver must be at a right-angle to the rear surface of the steering wheel.

Place the screwdriver point against the top of the spring clip as illustrated.

Pry the screwdriver up against the upper edge of the hole (2) so that the point of the screwdriver presses down the catch (1) until the catch releases.

Turn the steering wheel a 1/2 turn in the opposite direction. Repeat the process on the other side.

Turn the steering wheel to the neutral position.

Fold out the airbag.

Fig. 126: Identifying Airbag Removal

Courtesy of VOLVO CARS CORPORATION

Disconnect the 2 connectors (2) (there may be more or less) for the SRS ignition cables for the airbag.

Remove the airbag.

INSTALLATION

INSTALLING DRIVER'S AIRBAG (SRS)

NOTE: For airbags (replacement part) supplied without keypads, for Audio, RTI and cruise control for example, an upgrade kit must be ordered.

Install the 2 connectors (there may be more or fewer).

Press the airbag into place.

CAUTION: Ensure that the wiring is not trapped during installation.

Carry out an inspection as described in, see **SUPPLEMENTARY RESTRAINT SYSTEM (SRS), INSPECTION** .

AIRBAG MODULE SEAT (SIPS), REPLACING

see **AIRBAG MODULE SEAT (SIPS), REPLACING**

AIRBAG PASSENGER (SRS), REPLACING

see **AIRBAG PASSENGER (SRS), REPLACING**

BUCKLE SEAT BELT FRONT, REPLACING

see **BUCKLE SEAT BELT FRONT, REPLACING**

BUCKLE SEAT BELT REAR, REPLACING

see **BUCKLE SEAT BELT REAR, REPLACING**

COLLISION SENSOR B AND C-POST, REPLACING

see **COLLISION SENSOR B AND C-POST, REPLACING**

CONTACT REEL, REPLACEMENT

see **CONTACT REEL, REPLACEMENT**

END MOUNTING, REPLACING

see **END MOUNTING, REPLACING**

FORCE LIMITER MECHANICAL/BELT TENSION SENSOR, REPLACING (2005-2011)

NOTE: **The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.**

PREPARATORY WORK

IMPORTANT INFORMATION

The driver's seat always has a mechanical force limiter.

The passenger seat always has a force limiter with a belt tension sensor.

ADJUSTING THE SEAT POSITION

Move the seat as far forward as possible.

REMOVAL

REMOVING THE FORCE LIMITER/BELT TENSION SENSOR

Fig. 127: Identifying Seat Belt And Catch
Courtesy of VOLVO CARS CORPORATION

Remove the front seat side panel. See: **SIDE PANEL FRONT SEAT, REPLACING** .

Insert a screwdriver on the inside of the end mounting. Remove the seat belt by pressing the catch inwards and pulling upwards.

Fig. 128: Identifying Seat Belt Connector And Screw
Courtesy of VOLVO CARS CORPORATION

On the passenger seat, remove:

- the connector
- the screw
- the force limiter with belt tensioner sensor.

On the driver's seat, remove:

- the screw
- the mechanical force limiter.

INSTALLATION

NOTE: **For tightening torques, see: TIGHTENING TORQUE .**

INSTALLING THE FORCE LIMITER/BELT TENSION SENSOR

Install:

- the force limiter/sensor using the M10 screw. Tighten
- the connector (passenger seat only)
- the seat belt and end mounting
- the side panel. See: **SIDE PANEL FRONT SEAT, REPLACING** .

FINISHING

CHECKING THE SEAT BELT FUNCTION AND SUPPLEMENTARY RESTRAINT SYSTEM

Check the seat belt function. See: **SEAT BELT FUNCTION, CHECK** .

Carry out an inspection of the supplementary restraint system. See: **SUPPLEMENTARY RESTRAINT SYSTEM (SRS), INSPECTION** .

IC (INFLATABLE CURTAIN) MODULE, REPLACING

see **IC (INFLATABLE CURTAIN) MODULE, REPLACING**

SEAT BELT FRONT, REPLACING

SEATBELT FORCE LIMITER ADAPTIVE, REPLACING (2005-2011)

NOTE: **The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.**

PREPARATORY WORK

REMOVING THE BATTERY LEAD AND IMPORTANT INFORMATION

Fig. 129: Disconnecting Battery Negative Cable
Courtesy of VOLVO CARS CORPORATION

Ignition off.

Disconnect the battery negative lead. See: **BATTERY, DISCONNECTING** .

WARNING: **For information about the handling and storage of pyrotechnical SRS components, see: HANDLING NON-DEPLOYED SRS-COMPONENTS .**

WARNING: **Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed pyrotechnical SRS component. There is a risk of the seat belt tensioner deploying.**

WARNING: **Pyrotechnical SRS components must never be taken apart, repaired or transferred to another vehicle.**

REMOVAL

REMOVING THE ADAPTIVE SEATBELT FORCE LIMITER

Fig. 130: Identifying Adaptive Seatbelt Force Limiter
Courtesy of VOLVO CARS CORPORATION

Remove:

- the B-post panel. See: **PANEL B-POST, REPLACING**
- the 2 x SRS ignition cables (1)
- the connector (2).

Fig. 131: Identifying 3 Screws
Courtesy of VOLVO CARS CORPORATION

- the 3 screws
- the seat belt reel with the adaptive seatbelt force limiter.

INSTALLATION

INSTALLING THE ADAPTIVE SEATBELT FORCE LIMITER

Correctly align the seat belt reel.

Install:

- the 2 M10 screws. Tighten. See: **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**
- 1 screw. Tighten
- the connector
- the 2 x SRS ignition cables
- the B-post panel. See **PANEL B-POST, REPLACING** .

Connect the battery negative lead. See: **BATTERY, DISCONNECTING** .

OIL COOLER, TRANSMISSION (4T65 AWD; 2003-06)

OIL COOLER TRANSMISSION - FLUSHING AND CLEANING

WARNING: Avoid skin contact with the oil.

NOTE: When replacing the transmission, the oil cooler must always be flushed clean since there may be dirt or particles in the oil cooler.

PREPARATIONS

A vacuum oil extractor is used to suck the oil through the oil cooler when flushing the oil cooler.

The following material is required to flush the oil cooler:

Fig. 1: Identifying Vacuum Extractor
Courtesy of VOLVO CARS CORPORATION

Vacuum extractor.

Fig. 2: 5 L. Plastic Container
Courtesy of VOLVO CARS CORPORATION

5 litre plastic container.

Plastic hose

Inner diameter: 10 mm.

Length: 900 mm.

Assemble as shown.

Fig. 3: Cutting Pipe
Courtesy of VOLVO CARS CORPORATION

Upper oil hose and pipe. This oil hose must be on the upper section of the oil cooler.

Cut the pipe as shown. Smooth of the edge of the pipe.

NOTE: Blow the pipe clean.

Fig. 4: Identifying Splash Guard

Courtesy of VOLVO CARS CORPORATION

Connecting components to the vacuum extractor.

Remove the air cleaner (ACL) housing. See **BRAKE CONTROL MODULE (BCM), REPLACING** .

Raise the car. Remove the front air baffle.

Fig. 5: Gearbox Oil Pipe
Courtesy of VOLVO CARS CORPORATION

Slacken off the nut on the return line for the oil pipe bracket a few turns.

Remove the screw nipple on the oil return line from the connection. Counterhold in the gearbox.

Fig. 6: Identifying Plastic Hose Installed On Oil Return Line
Courtesy of VOLVO CARS CORPORATION

Pull out the oil pipe. Plug the connections in the gearbox.

Press a 10 mm diameter plastic hose (compressed air hose) into place.

Length: 200 mm on the lower oil pipe.

Clamp the hose into place in the sub-frame.

Lower the car.

DETACHING AND INSTALLING THE UPPER OIL HOSE AND PIPE

Detach and push the upper oil hose away from the oil cooler.

Fig. 7: Cutting Pipe
Courtesy of VOLVO CARS CORPORATION

Install the cut oil hose and pipe on the oil cooler.

Filling with oil

Fill the plastic container with 2 litres of oil.

NOTE: **Oil grade: Only ATF fluid Dexron III (with G-license).**

Transmission oil, Volvo part number 116 1521-8 (1-liter container), 116 1621-6 (4-liter container).

Fig. 8: Plastic Container Hanging Under Hood
Courtesy of VOLVO CARS CORPORATION

Connect the hose from the plastic container to the cut oil pipe. Hang the plastic container under the bonnet.

Raise the car.

FLUSHING

Charge the vacuum extractor.

Fig. 9: Connecting Vacuum Extractor
Courtesy of VOLVO CARS CORPORATION

Connecting the vacuum extractor

Connect an oil pipe with an external diameter of 10 mm from the vacuum extractor. Connect the oil pipe to the short hose.

Flushing

Open the cock and suck the oil out of the oil cooler. Check that the filler container is not completely drained. (There should be a little oil left in the hose.) Flow: 2 litres take approximately 40 seconds.

If the level sinks slowly the flushing must be repeated. If the level still sinks slowly replace the oil cooler.

REINSTALLATION

Fig. 10: Identifying Plastic Hose Installed On Oil Return Line
Courtesy of VOLVO CARS CORPORATION

Remove the hose and reinstall:

The oil return line on the gearbox.

The oil pipe and screw nipple on the connection.

Tighten to **30 Nm** .

Fig. 11: Gearbox Oil Pipe
Courtesy of VOLVO CARS CORPORATION

Tighten the nut for the oil pipe bracket. Tighten to **25 Nm** .

Reinstall the air baffle.

Lower the car.

Fig. 12: Plastic Container Hanging Under Hood
Courtesy of VOLVO CARS CORPORATION

Remove the plastic container and the oil pipe from the oil cooler.

Reinstall the existing oil hose on the oil cooler.

Checking the gearbox fluid level

Check the level. See **OIL LEVEL, CHECKING** .

Miscellaneous - Design and Function

GENERATOR (GEN) (2005-2012)

DESIGN

GENERATOR (GEN) DESIGN

Fig. 1: Generator Design
Courtesy of VOLVO CARS CORPORATION

The main components of the generator (GEN) consist of:

1. Stator
2. Rotor with slip rings
3. Integrated cooling fans
4. DC bridge
5. Charge regulator
6. Pulley.

Generator terminals

Fig. 2: Identifying Generator Terminals
Courtesy of VOLVO CARS CORPORATION

Generator (GEN) terminals:

- #A:1. B+
- #B:1. To central electronic module (CEM) or engine control module (ECM).

ALTERNATOR STRUCTURE, ENGINE B8444S

Fig. 3: Identifying Generator Components
Courtesy of VOLVO CARS CORPORATION

The main components of the generator (GEN) consist of:

1. Stator
2. Rotor with slip rings
3. Integrated cooling fans
4. DC bridge
5. Charge regulator
6. Pulley.

Alternator connections, engine B8444S

Fig. 4: Identifying Generator (GEN) Terminals
Courtesy of VOLVO CARS CORPORATION

Generator (GEN) terminals:

- #A:1. B+
- #B:1. To engine control module (ECM)
- #B:2. Not used

STATOR

Fig. 5: Identifying Stator
Courtesy of VOLVO CARS CORPORATION

The stator is fixed and consists of grooved plates which are insulated internally and pressed together onto a fixed plate unit. The stator winding coils are positioned in the grooves. They are delta connected at 120° and provide a three phase alternating current to the rectifier bridge.

ROTOR WITH SLIP RINGS

Fig. 6: Identifying Rotor With Slip Rings
Courtesy of VOLVO CARS CORPORATION

The rotor consists of two halves (claw-poles) which interlock. The halves are pressed onto the rotor shaft. There are twelve claws on the rotor, i. e. twelve poles. One half consists of six north poles and the other half six south poles. The excitation winding is secured on the rotor shaft between the claw-pole halves. The excitation winding (also known as rotor winding) consists of a circular coil surrounded by the claw-poles and connected to the slip rings. The charge regulator supplies a magnetic current through carbon brushes positioned against the slip rings. The higher the current in the rotor the stronger the magnet field of the rotor, and therefore the higher the current generated in the windings of the stator.

COOLING FANS

Fig. 7: Cooling Fans
Courtesy of VOLVO CARS CORPORATION

The heat generated in the generator is, in principle, proportional to the current generated and must be directed away to prevent damage to the insulation and diodes. The generator (GEN) is therefore air cooled and equipped with two integrated cooling fans on the rotor shaft.

RECTIFIER

Fig. 8: Identifying Rectifier
Courtesy of VOLVO CARS CORPORATION

Alternating current (AC) is created in the generator stator windings. This must be converted to direct current (DC) before it can be used in the electrical system of the car. This conversion is made using a rectifier bridge which consists of six diodes, two diodes per phase winding.

The stator windings generate three phases and are delta connected An exciter diode is connected to each of the three stator windings. The six rectifier diodes are bridge connected. The diodes are pressed into a diode holder.

CHARGE REGULATOR (ALTERNATOR CONTROL MODULE (ACM))

General

Fig. 9: Charge Regulator
Courtesy of VOLVO CARS CORPORATION

For B8444S

Fig. 10: Identifying Charge Regulator Bracket & Connector
Courtesy of VOLVO CARS CORPORATION

The generator (GEN) has an inbuilt charge regulator at the rear (also known as the alternator control module (ACM)). The regulator can be replaced. The carbon brushes are integrated on the slip rings on the rotor on the regulator.

Charge voltage

At room temperature a fully charged battery cell produces 2.12 V. A 12 V battery has 6 cells and therefore produces 12.72 V when the battery is fully charged. The battery has an internal resistance which must be exceeded before charging can take place. At room temperature 0.2 V is required per cell, or 1.2 V for the entire battery. Therefore to charge a battery at room temperature, 13.92 V (12.72 V+1.2 V) is required. In cold conditions, the chemical reactions take place at a slower rate and the internal resistance increases. This requires a higher voltage during charging to exceed the internal resistance. The charge regulator, depending on how it is controlled by the central electronic module (CEM), regulates the output voltage so that the battery receives

optimal charge.

If the charge regulator is connected to the engine control module (ECM), it will use the commands from the engine control module (ECM) and central electronic module (CEM) to regulate output voltage so that the battery is charged optimally.

Charge regulator control

Fig. 11: Generator And Alternator Control Module
Courtesy of VOLVO CARS CORPORATION

Fig. 12: Identifying ACM, ECM & CEM Communication Link
Courtesy of VOLVO CARS CORPORATION

The above illustrations depict the two different types of connections for the alternator's regulator.

Depending on the model year and type of engine management system, the charge regulator (also known as the alternator control module (ACM)) is connected to either the central electronic module (CEM) or the engine control module (ECM). It communicates via LIN communication.

If the charge regulator is connected to the engine control module (ECM), the engine control module (ECM) then communicates with the central electronic module (CEM) regarding alternator control via the controller area network (CAN).

The central electronic module (CEM) has built-in functions for regulating voltage level and current consumption in the vehicle. The central electronic module (CEM) controls the charge regulator either directly or via the engine control module (ECM). In this manner, it also controls the current/voltage produced by the alternator.

The generator does not initially charge when the engine is started. The charge increases successively when the engine has been started. When there is an increase in load at the generator, the increase from 0 - 100% takes place over the course of a few seconds (this time varies slightly depending on the operating mode the engine management system is in). This is to gradually increase the load on the engine during the start-up phase and to ensure the engine starts.

If the engine speed (RPM) exceeds idle speed (the exact engine speed varies slightly depending on the mode the engine management system is in) during this delay, or if the progressive increase is interrupted, full charge is obtained immediately.

If there is no communication with the charge regulator, the charge regulator will not start charging on start-up. The charge regulator can however self magnetize the rotor and start charging. This occurs at engine speeds greater than approximately 2100 rpm. There is no charge engagement by stages with self magnetization, the generator operates at full charge immediately.

When self magnetizing has begun, the generator (GEN) also charges at engine speeds below 2100 rpm.

FREEWHEEL

Fig. 13: Freewheel Generator
Courtesy of VOLVO CARS CORPORATION

Some alternators are fitted with freewheels between the rotor shaft and the pulley. However, it is possible to, see that the pulley is fitted with freewheels from the cover fitted over the pulley's nut in the centre. The freewheels allow the alternator's rotor shaft to rotate freely in one direction. This keeps any jerking in the belt transmission to a minimum. For engine B8444S, the alternator is not fitted with freewheels.

FUNCTION

GENERAL

Fig. 14: Identifying ACM To CEM Communication Link
Courtesy of VOLVO CARS CORPORATION

Fig. 15: Identifying ACM, ECM & CEM Communication Link
Courtesy of VOLVO CARS CORPORATION

The above illustrations depict the two different types of connections for the alternator's regulator.

Output voltage from the generator (GEN) is calculated from the calculated battery temperature in order to charge the battery fully. The central electronic module (CEM) calculates the battery temperature using the outside temperature. The outside temperature is obtained from the outside temperature sensor.

The Rear electronic module (REM) checks the voltage on the battery and transmits the value out on the CAN network. The value is used in the Central electronic module (CEM), among others, for diagnosing the charging function.

CHARGING

When the ignition key is in position II (or III), the central electronic module (CEM) sends information to the charge regulator (also known as the alternator control module (ACM)) either directly or via the engine control module (ECM).

The regulator directs current to the excitation winding rotor and is then grounded via the regulator. When the current travels through the rotor a magnetic field is formed around the rotor. When the engine is started and the

rotor begins to rotate, the magnetic field also rotates and then produces alternating current in the stator windings.

Alternating current is rectified when it passes the diodes and is then fed to the electrical system of the vehicle. The voltage obtained from the stator winding also passes to the regulator via the rectifier and affects the control functions.

The desired charge voltage (desired value), based on factors such as calculated battery temperature, is sent from the central electronic module (CEM) to the charge regulator either directly or via the engine control module (ECM). The regulator then controls so that the desired voltage is obtained by the battery.

The charge indicator lamp in the combined instrument panel is controlled by the driver information module (DIM) via signals from the controller area network (CAN).

SYSTEM OVERVIEW

GENERAL

Fig. 16: Freewheel Generator
Courtesy of VOLVO CARS CORPORATION

This document describes the basic principles of the design and function of the generator (GEN), irrespective of the make.

The generator provides power consuming components with current whilst the engine is running and maintains battery charge. The generator (GEN) is mounted on the front edge of the engine.

The output of the generator (GEN) depends on engine speed. When the engine is idling, the generator (GEN) operates at approximately half of maximum output. When the engine is idling with many power consuming components engaged, the generator (GEN) may be unable to maintain full battery charge.

In cold conditions the capacity of the battery to receive charge is lower than at room temperature. This means that, when the engine is idling for a long period with a large number of power consuming components connected, the battery may discharge.

If the generator charge is cut, the power consuming components of the vehicle are only supplied with energy

from the battery, which means that the battery will eventually run flat.

First of all the generator (GEN) creates an alternating current (AC) which is converted to a direct current (DC) in the rectifier bridge.

The alternator has a built-in charge regulator (also known as the alternator control module (ACM)).

NOTE: Depending on the model year and type of engine management system, the charge regulator is connected to either the central electronic module (CEM) or the engine control module (ECM). It communicates via LIN communication.

The auxiliaries belt transfers power from the crankshaft pulley to the auxiliaries such as the power steering pump, air conditioning (A/C) compressor, and the generator. An automatic belt tensioner is used to adjust the belt tension. The belt is a Poly-v-belt.

The alternator with charge regulator is diagnosed via the central electronic module (CEM) provided the charge regulator is connected to the central electronic module (CEM).

If the charge regulator is connected to the engine control module (ECM), it is diagnosed by both the central electronic module (CEM) and the engine control module (ECM).

The charge indicator lamp in the combined instrument panel is controlled by the driver information module (DIM) via signals from the controller area network (CAN).

GLOBAL POSITIONING SYSTEM MODULE (GPS) (2007-2012)

DESIGN

CONTROL MODULE

Fig. 17: Identifying Global Positioning System Module (GPS)
Courtesy of VOLVO CARS CORPORATION

The global positioning system module (GPS) has a built-in 12 channel GPS receiver. The receiver is optimized for a frequency of 1575.42 MHz.

The global positioning system module (GPS) transmits two signals:

- A signal to the infotainment control module (ICM) indicating that the control module is awake.
- A combination signal to the Phone module (PHM). Current, received position is transmitted when it is available, otherwise a calculated position is transmitted, based on the last known received position.

If there is no, or poor communication, with the GPS satellites, for example when in a tunnel, the global positioning system module (GPS) uses the information from other control modules for dead reckoning (i. e. to calculate the position of the vehicle).

The global positioning system module (GPS) requires the following to calculate the actual position:

- the information from the wheel rotation counters stored in the brake control module (BCM)
- information about back-up (reverse) gear from the transmission control module (TCM)
- information about whether the parking brake is applied from the driver information module (DIM)
- information about whether the brake pedal is pressed or not from the brake control module (BCM)
- information about the extent to which the traction control system is activated from the brake control module (BCM)
- information about wheel size from the central electronic module (CEM).

All information is transmitted via the infotainment control module (ICM).

The navigation system needs signals from at least three GPS satellites to calculate the position of the vehicle in two planes.

For three dimensional position reckoning, signals are required from at least four satellites.

The position is measured both vertically and horizontally. The antenna continuously transmits information about the position of the vehicle to the GPS receiver. The position is accurate to within a maximum of 25 meters from the position calculated by both the GPS signal and dead reckoning. The accuracy is somewhat reduced when only dead reckoning is used. The fault increases with distance driven since position lost.

If there is signal interference, when traveling in tunnels or high rise areas for example, the accuracy may be reduced slightly.

For the system to determine the position as exactly as possible, the system must differentiate between signals coming directly the GPS satellites or those reflected by a high rise building for example.

When the ignition is switched off the power consumption of the GPS receiver must not exceed 0.1 mA. The receiver stores important information, such as the last GPS signal received if the power is cut.

The system can endure temperatures between -40 °C and 85 °C.

The global positioning system module (GPS) checks the input and output signals through an integrated diagnostic system.

NOTE: **If the diagnostic information indicates a lost GPS signal, the signal should be checked outdoors. This is because the signal may be blocked if the vehicle is indoors.**

ANTENNA

Fig. 18: Locating GPS Antenna
Courtesy of VOLVO CARS CORPORATION

The global positioning system has an antenna. This antenna is a combined antenna for GPS and the carphone.

The GPS receiver supplies the antenna power at 0 - 4.75 ±0.5 V via a coaxial cable.

The antenna is located in front of the inner rear view mirror.

DIAGNOSTIC FUNCTIONS

GENERAL

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault.

If a fault disappears for any reason after the diagnostic trouble code (DTC) has been permanently stored in the control module, information about the fault remains in the control module.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes can only be erased once all the diagnostic trouble codes have been read out at least once.

NOTE: Certain functions are unavailable until the diagnostic trouble codes (DTCs) have been erased.

READING OFF INPUT AND OUTPUT SIGNALS

This function can be used to continuously read off the values and status of the control module's input and output signals.

The following parameters can be read off:

- **GPS Received position, longitude.** Indicates the received longitudinal position.
- **GPS Received position, latitude.** Indicates the received latitudinal position.

The following responses may be obtained when reading the available GPS satellites:

- Not available - no contact with satellites.
- No fix - contact with satellites but unable to fix a position.
- 2D Fix- contact with satellites, two-dimensional position fixing.
- 3D Fix- contact with satellites, three-dimensional position fixing.

READING OFF THE CONTROL MODULE IDENTIFICATION

The diagnostic tool identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N

READING OFF EXTENDED FAULT-TRACING INFORMATION

This function can be used to read parameters, status identifiers and counters stored at the same time as a diagnostic trouble code (DTC). These are called frozen values.

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

Software can be downloaded to the global positioning system module (GPS). When software is ordered, the vehicle' software and hardware is compared to Volvo's central database. If they are compatible, the software is downloaded to the system.

If the comparison between the car and Volvo's central database does not correspond, then the database is updated with the vehicle's configuration. When this is complete the software is downloaded.

After replacing the control module the module's unique ID number must be programmed in the Central electronic module (CEM).

FUNCTION

GPS RECEPTION

Fig. 19: Identifying GPS Components
Courtesy of VOLVO CARS CORPORATION

The GPS receiver receives signals from GPS satellites. The Global positioning system module (GPS) (16/139) transmits signals onwards via the MOST network to:

- Phone module (PHM) (16/60)
- Infotainment control module (ICM) (16/94).

The signal to the Phone module (PHM) is used by Volvo on Call/ Volvo on Call Plus to locate the vehicle in an emergency situation.

The signal to the Infotainment control module (ICM) is a confirmation that the control module is awake.

When starting from cold, the system must be able to determine the position of the car within 120 seconds. For hot starting the position must be available within 40 seconds.

A cold start is when the system has had no power for a long period. A hot start is where the system has been off for a shorter time, when the car has been in a short-stay car park for example. This does not apply to locations without GPS reception, for example, when the car is inside a garage.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 20: Locating GPS Module
Courtesy of VOLVO CARS CORPORATION

The global positioning system module (GPS) receives satellite signals to determine position.

The global positioning system module (GPS) is an option and is only used together with Volvo on Call and when the vehicle is equipped with Multimedia module (MMM).

The Global positioning system module (GPS) is located under the left-hand seat.

The global positioning system has an antenna. This antenna is a combined antenna for GPS and the carphone.

The control module uses optical serial communication to communicate with other components on the MOST network. This means that all communication with the Global positioning system module (GPS) is via the infotainment control module (ICM).

The control module checks input and output signals via an integrated diagnostic system. A diagnostic trouble code (DTC) is stored if the control module detects an error. Any diagnostic trouble codes (DTCs) are stored in the control module memory.

The information can be read off using the diagnostic tool.

SIGNALS

The table below summarizes the input signals to and output signals from the global positioning system module (GPS).

The signal types are divided into directly connected signals and MOST communication.

The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: • Antenna (16/64)	**Directly connected:** -
Via MOST communication:	**Via MOST communication:**

• Infotainment control module (ICM) (16/94)	• Infotainment control module (ICM) (16/94) • Phone module (PHM) (16/60)

Fig. 21: Identifying Volvo Component Designations

HEADLAMP WASHER (2003-2012)

HEADLAMP WASHER

WASHING

Fig. 22: Identifying Headlamp Washers
Courtesy of VOLVO CARS CORPORATION

1. Washing off
2. Washing on
3. Spray pattern
4. Washer nozzle.

The XC90 has a system to clean the headlamp lenses. This is telescopic with double nozzles installed in the bumper under each headlamp.

Function

- Each telescopic arm consists of a hollow piston which runs inside a cylinder
- When washing, the pressure of the washer fluid presses the piston out
- When the piston is in the deployed position, a relief valve opens and the fluid can move into the nozzle
- When the pressure drops again, a return spring returns the piston into the cylinder
- The washer nozzle has a unique spray pattern
- The telescopic arm has a stroke of 120 mm
- Color coordinated covers lie over the bumper in the resting position.

NOTE: Each washer nozzle is specially adapted for either the right or left-hand headlamp. Color coded: Right =gray, Left = black.

SYSTEM OVERVIEW

Fig. 23: Identifying Headlamp Washer System
Courtesy of VOLVO CARS CORPORATION

1. Windshield washer reservoir
2. Pump
3. Relay
4. Central electronic module (CEM)
5. Steering wheel module (SWM)
6. Telescopic arm
7. Washer nozzle
8. Cover.

Pump

An electrical centrifugal pump increases the pressure of the fluid in the system. The windshield washer fluid presses the pistons out and then flows out through the nozzles and cleans the headlamps.

- The pump is on the windshield washer reservoir at the pumps for the front and rear windshields
- The motor is activated for 1 second for each wash
- Maximum pump pressure = 4 bar
- Output: 180 W.

Washing

Approximately 1 dl of washer fluid is used for each wash.

The capacity of the windshield washer reservoir is 6.5 liters.

HEADLIGHT CONTROL MODULE (HCM) (2007-2012)

DESIGN

LEFT HEADLIGHT CONTROL UNIT (LHCU) / RIGHT HEADLIGHT CONTROL UNIT (RHCU)

Fig. 24: Identifying Left And Right Headlight Units
Courtesy of VOLVO CARS CORPORATION

The left headlight control unit (LHCU) / right headlight control unit (RHCU) are located within the headlights.

The left headlight control unit (LHCU) / right headlight control unit (RHCU) handle the active regulation of the light beam. Active regulation means that the light beam is turned out to the left or right. The light beam is turned out at different amounts and different rates depending on vehicle speed and steering wheel angle.

Information is transferred between the left headlight control unit (LHCU), right headlight control unit (RHCU) and headlight control module (HCM) via LIN communication.

The lamp housing contains a sensor that indicates whether the light beam has been turned out to the right or left. The left headlight control unit (LHCU) and right headlight control unit (RHCU) send this information to the headlight control module (HCM).

If there is no communication with the headlight control module (HCM) or a fault arises in the left headlight

control unit and/or the right headlight control unit (RHCU), active regulation ceases. If this is the case, the headlights are aimed straight ahead.

The left headlight control unit (LHCU) and right headlight control unit (RHCU) can be diagnosed.

DIAGNOSTIC FUNCTIONS

GENERAL

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. A fault which is detected in the most recent operating cycle is defined as permanent. Other faults are defined as intermittent. An operating cycle involves ignition on, the vehicle speed exceeding 20 km/h and the ignition being switched off.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF INPUT AND OUTPUT SIGNALS

This function can be used to continuously read off the status of the control module's input and output signals.

ACTIVATING COMPONENTS

This function can be used to activate components to check that they are working.

READING OFF THE CONTROL MODULE IDENTIFICATION

The diagnostic tool identifies control modules by reading off a number of codes from the control module memory.

The codes contain the following information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N (part of the software).

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded to the headlight control module (HCM).

When ordering software the vehicle's hardware and software are compared with Volvo's central database. If the comparison is correct the software is downloaded to the control module.

If the comparison between the car and Volvo's central database does not correspond, then the database is updated with the vehicle's configuration. When this is complete the software is downloaded.

FUNCTION

ACTIVE HEADLIGHTS

Fig. 25: Identifying Headlight Control Module (HCM) System Communication Links
Courtesy of VOLVO CARS CORPORATION

Active headlights are an intelligent headlight system that optimizes illumination of the road surface at night by turning out the light beam. The motorized headlights are controlled by the headlight control module (HCM), which retrieves signals from the CAN network.

In order to activate the active headlight function, the headlight control module (HCM) (4/118) needs information on the following: vehicle speed, current gear, light conditions.

The headlight control module (HCM) receives information from the following control modules:

- Brake control module (BCM) (4/16) for information on vehicle speed
- Transmission control module (TCM) (4/28) for information on current gear (automatic transmission)
- Central electronic module (CEM) (4/56) for information from the reversing light switch (3/10) (manual transmission)
- Central electronic module (CEM) for information from the twilight sensor (7/12)

The headlight control module (HCM) is activated automatically when the ignition switch is turned to position II. In order to turn out the light beam, the following conditions must be fulfilled:

- The vehicle must be in motion, that is to say travelling at a speed greater than 3.6 km/h (2.2 mph).
- Reverse gear must not be engaged.
- No daylight light conditions.

The switch for active headlights on the climate control module (CCM) (3/112) can be used to disable/enable the function.

When the function is active, the headlight control module (HCM) receives continual information on vehicle speed and steering angle. Vehicle speed is obtained from the brake control module (BCM) while steering angle information comes from the steering wheel angle sensor module (SAS) (3/254). This information enables the headlight control module (HCM) to calculate the current turn-out of the light beam.

SHIFT LIGHT BEAM AND LIMIT ACTIVE CONTROL FOR RIGHT-HAND/LEFT-HAND TRAFFIC ("TOURIST MODE")

Fig. 26: Identifying Shift Light Beam Patterns For Right-Hand/Left-Hand Traffic
Courtesy of VOLVO CARS CORPORATION

NOTE: Changing light pattern and limiting active control is only permitted on certain markets. The function is controlled by the software in Headlamp Control Module (HCM).

If the vehicle is designed for right-hand traffic and is used in a country where traffic drives on the left, the light beam must be shifted and active control limited so as not to blind oncoming traffic. This also applies if the vehicle is designed for left-hand traffic and is used in a country where traffic drives on the right.

In order to change the setting, hold the active headlight switch on the climate control module (CCM) depressed for at least five seconds.

When the setting has been changed, a message appears in the driver information module to indicate the current setting (for right-hand or left-hand traffic) of the vehicle.

When the setting has been changed and the vehicle is in "tourist mode":

- When driving straight ahead, the light beam is turned in a suitable direction so as not to blind oncoming traffic.
- As before, the light beam will also be turned out in the suitable direction when cornering, just not as much.
- The light beam is also aimed down slightly (shorter beam length) so as not to blind oncoming traffic.

The vehicle must be stationary when the setting is changed.

NOTE: The light beam must under no circumstances be adjusted with the adjuster screws when in "tourist mode". If the light beam is adjusted with the adjuster screws when the system has aimed the headlights down, there is a substantial risk that the vehicle will blind oncoming traffic when the system resumes normal mode.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 27: Locating Headlight Control Module (HCM)
Courtesy of VOLVO CARS CORPORATION

The most important task of the headlight control module (HCM) is handling the active headlight function.

The control module is mounted beneath the driver's seat. The entire control module is removed from the vehicle upon replacement.

The headlight control module (HCM) communicates both with directly connected components, and with other control modules via CAN communication.

The control module checks activations and input and output signals using an integrated diagnostic system A diagnostic trouble code is generated if the control module detects a fault. In certain cases the control module replaces the faulty signal with a substitute value.

Any diagnostic trouble codes are stored in the relevant control module memory. The data can be read off using a diagnostic tool.

If the control module detects a fault, a diagnostic trouble code is registered in the control module's internal memory. At the same time, a number of values that were frozen when the fault occurred are store. Depending on the severity of the fault, some functions will be fully or partially disabled. A warning or information text will appear in the driver information module (DIM) display. In addition, the LED in the active headlight button will flash. Diagnostic trouble codes and frozen values (detailed diagnostic trouble code information) can be read with a diagnostic tool via the data link connector in the vehicle.

In order to check whether the headlight control module (HCM) is supplied power and is grounded, the ignition switch can be set to position II.

SIGNALS

The table below summarizes the input signals to and output signals from the headlight control module (HCM). The signal types are divided into LIN communication and CAN communication. The illustration below displays the same information with the Volvo component designations.

Input signals:	Output signals:
Via LIN communication: • Left headlight control unit (LHCU) / right headlight control unit (RHCU)	**Via LIN communication:** • Left headlight control unit (LHCU) / right headlight control unit (RHCU)
Via CAN communication: • Transmission Control Module (TCM) (4/28) • Brake control module (BCM) (4/16) • Steering wheel angle sensor module (SAS) (3/254) • Climate Control Module (CCM) (3/112). • Central electronic module (CEM) (4/56)	**Via CAN communication:** • Driver information module (DIM) (5/1) • Climate Control Module (CCM) (3/112). • Central electronic module (CEM) (4/56)

Fig. 28: Identifying Headlight Control Module (HCM) Communication System Links

IMMOBILIZER (2003-2004)

DESIGN

GENERAL

The security system in the vehicle is a distributed system which is monitored by the central electronic module (CEM). A number of other units and components are involved for the various functions.

CENTRAL ELECTRONIC MODULE (CEM)

Fig. 29: Central Electronic Module
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) (4/56) is the master unit for the immobilizer function. The central electronic module (CEM) and engine control module (ECM) are linked to each other through codes. The central electronic module (CEM) is also programmed with a code for each ignition key for the vehicle.

The central electronic module (CEM) transmits commands and signals to the other units in the system. The central electronic module (CEM) also approves the identity of the key. The key is checked via the antenna ring. The antenna ring is installed around the ignition switch. There is a transponder (communication circuit) in the ignition key. The identification code of the transponder is unique. The code must be learned by the central electronic module (CEM) before the key can be used to start the vehicle. This code is learned during at the factory. New keys can be added afterwards.

The central electronic module (CEM) checks the relay for the starter motor.

ANTENNA RING

Fig. 30: Antenna Ring

Courtesy of VOLVO CARS CORPORATION

The antenna ring (16/65) is installed around the ignition switch. The antenna ring is used to allow the central electronic module (CEM) to communicate remotely with the ignition key.

The antenna ring comprises a modulation circuit and a communication circuit. The modulation circuit converts signals between the central electronic module (CEM) and the communication circuit. The communication circuit is used to communicate with the key.

When the central electronic module (CEM) activates the antenna ring, a magnetic field is generated around the antenna ring. This magnetic field is converted in the key to an electrical current, which means that the key does not require further electrical supply.

IGNITION KEY

Fig. 31: Identifying Ignition Key Transponder
Courtesy of VOLVO CARS CORPORATION

There is a communication circuit in the ignition key, known as a transponder. This circuit is supplied with power from the magnetic field that is formed around the antenna ring when the central electronic module (CEM) activates the antenna ring. Consequently, the transponder is not dependent on a further power supply.

In order for the key to be used in the vehicle, a code in the key must be entered by the central electronic module (CEM). When the vehicle is delivered from the factory, two keys are normally programmed. When a key has been programmed for the central electronic module (CEM), the key is locked and cannot be programmed for another vehicle.

ENGINE CONTROL MODULE (ECM)

Fig. 32: Engine Control Module
Courtesy of VOLVO CARS CORPORATION

Engine control module (ECM) (4/46) checks the ignition system in the vehicle. The engine control module (ECM) also grants permission to the central electronic module (CEM) if the starter motor is to be allowed to operate when attempting to start. The functions are activated after an approved check of the ignition key has been carried out and an approved identity check has been performed between the engine control module (ECM) and the central electronic module (CEM).

In order for the engine control module (ECM) to work in the immobilizer system, the control module must be programmed with codes. This takes place the first time during installation at the factory, and then if the control module is replaced (when downloading software).

DRIVER INFORMATION MODULE (DIM)

Fig. 33: Driver Information Module

Courtesy of VOLVO CARS CORPORATION

The driver information module (DIM) (5/1) receives information from the central electronic module (CEM) about which message is to appear in the display. A message will be displayed if there is a fault in any of the checks run by the system.

DIAGNOSTIC FUNCTIONS

GENERAL

The central electronic module (CEM) is the master unit for the immobilizer. The central electronic module (CEM) also directly stores diagnostic trouble codes (DTCs) for faults in the immobilizer system. Some other faults can also be stored in the engine control module (ECM).

PROGRAMMING

To increase the security of the immobilizer system, the central electronic module (CEM) and the engine control module (ECM) are linked to each other with codes. The codes must be programmed if a control module is replaced before the vehicle can be started. Programming replaced control modules takes place automatically when downloading software into the new control module.

PROGRAMMING IGNITION KEYS

Ignition keys can be added and erased. A maximum of 6 key IDs can be programmed into the central electronic module (CEM). When programming a key, the key is identified to the control module with a code that is stored in the control module memory.

When a key is programmed for the vehicle, the remote control code is also entered if this is to be linked to the vehicle. However, the remote control code has nothing to do with the immobilizer system.

If a new key is added to a vehicle, the transponder in the key for this vehicle is locked and consequently cannot be programmed for another vehicle.

The erase function is used when the customer wishes to prevent one or more keys from being used to start the vehicle. The keys may have been stolen and could be traced back to the vehicle.

NOTE: **The following applies for model year 2004: Ignition keys and remote controls are integrated. Therefore the code for the remote control and the transponder must be available when programming. These are programmed at the same time. This means that a key that has been erased can be programmed back into the same vehicle if both these keys are available. The codes are on the packaging in which the keys are supplied. If the codes are not available, a new ignition key must be ordered.**

Keys are programmed via VIDA vehicle communication.

FUNCTION

THE IMMOBILIZER SYSTEM

The function of the immobilizer is to make the vehicle unusable unless a genuine Volvo key that belongs to the vehicle is used. When the ignition key is turned to position II, a check is performed electronically to ensure that the correct key is being used. If the key is not approved, the engine will not start. The function of the system will not be noticed by the customer as long as an approved key is used and there are no faults.

Fig. 34: Identifying Immobilizer Function
Courtesy of VOLVO CARS CORPORATION

Deactivation

When the ignition key is turned to position II, the central electronic module (CEM) performs an identity check of the transponder in the key via the antenna ring. In response, the central electronic module (CEM) receives a code from the transponder, which is compared to the codes that are stored in the central electronic module (CEM). If the codes correspond, the key is approved.

At the same time, the central electronic module (CEM) activates the relay for the starter motor and commences an identity check between the central electronic module (CEM) and the engine control module (ECM). The engine control module (ECM) transmits a code to the central electronic module (CEM) and receives a code back. The central electronic module (CEM) also transmits the results of the key check to the engine control module (ECM). If the identity check between the engine control module (ECM) and the central electronic module (CEM) as well as the check on the key are OK, the engine control module (ECM) will transmit a command to the central electronic module (CEM) that the starter motor may be activated. The engine control module (ECM) will then also activate the ignition system.

NOTE: **The engine control module (ECM) allows the starter motor to turn once the identity check between the engine control module (ECM) and the central electronic module (CEM) is complete. The starter motor will not be allowed to operate until the check on the ignition key is complete. Depending on the outcome of these two checks, the engine control module (ECM) will then determine whether the starter motor is to be allowed to operate.**

If either of the checks fails, a message will appear in the display on the driver information module (DIM) and the engine will not start.

Activation

The immobilizer system is activated when the ignition key is turned to position 0 and the engine stops. The engine control module (ECM) then sends a command to the central electronic module (CEM) that the starter motor is no longer permitted to turn.

The immobilizer system contains safety functions for preventing the system from being activated in the event the engine should stop while the ignition is still switched on. In this case the engine control module (ECM) will wait for a while before a command is sent to the central electronic module (CEM) indicating that the immobilizer is to be activated. If an attempt is made to start the vehicle within this time, there will be no new communication between the engine control module (ECM) and the central electronic module (CEM).

The immobilizer system will neither be activated if the vehicle is still moving when the engine stops. Similarly, the engine will not stop if the engine control module (ECM) conducts an internal restart while driving.

If the ignition key is turned to position 0 but the key is not removed from the ignition switch, the engine control module (ECM) will wait for a while but then send a command to the central electronic module (CEM) to activate the immobilizer, despite the fact that the key has not been removed from the ignition switch.

ERROR MESSAGE IN THE DRIVER INFORMATION MODULE (DIM).

Two different error messages may be displayed in the Driver information module (DIM) display for the immobilizer function.

NOTE: Because the information is sensitive to change the exact wording cannot be written here.

1. **Message regarding fault in the system for the immobilizer with reference to the user manual.** The message is displayed when a problem has occurred in communication between the Central electronic module (CEM) and the Engine control module (ECM).
2. **Message regarding prevented start with new attempt request.** The message is displayed if a fault has occurred when reading the transponder in the key.

For further information, see Diagnostic trouble code (DTC) information for the relevant diagnostic trouble codes (DTCs) in the Information manager.

SYSTEM OVERVIEW

GENERAL

Fig. 35: Immobilizer System Overview
Courtesy of VOLVO CARS CORPORATION

The immobilizer system increases the level of the vehicle safety system by making it extremely difficult to use the vehicle unless a valid key, which belongs to the vehicle, is used to start it. The identity of the key is checked when the vehicle is started, and if the key is not approved the engine will not start. The customer will not notice this function as long as a valid key is used an no fault occurs.

The immobilizer system includes:

- Central electronic module (CEM)
- Engine control module (ECM)
- Antenna ring
- Driver information module (DIM).

Definitions:

Activated system: The system means that the vehicle cannot be started.

Deactivated system: The key has been checked and approved. The system permits the car to start.

SIGNALS

The tables below summarize the input and output signals to the units in the system for the immobilizer. The signal types are divided into directly connected signals, serial communication and controller area network (CAN) communication.

CENTRAL ELECTRONIC MODULE (CEM) (4/56)

Input signals	Output signals
Directly connected: • Input signals from the switches for the different key positions (I, II, III) in the ignition switch.	**Directly connected:** • Starter motor relay for activating the starter motor.
Via serial communication (LIN):	**Via serial communication (LIN):**

• Antenna ring for communication with the key.	• Antenna ring for communication with the key.
Via CAN communication (LS-CAN): -	**Via CAN communication (LS-CAN):** • Driver information module (DIM) for displaying messages.
Via CAN communication (HS-CAN): • Engine control module (ECM) with information about the status of the engine for the immobilizer function.	**Via CAN communication (HS-CAN):** • Engine control module (ECM) for communication and to check the identity.

ANTENNA RING (16/65)

Input signals	Output signals
Via serial communication: • Central electronic module (CEM) for communication with the key.	**Via serial communication:** • Central electronic module (CEM) for communication with the key.

ENGINE CONTROL MODULE (ECM) (4/46)

Input signals	Output signals
Via CAN communication (HS-CAN): • Communication with the central electronic module (CEM) during start attempts.	**Via CAN communication (HS-CAN):** • Information about the status of the engine • Communication with the central electronic module (CEM) during start attempts.

DRIVER INFORMATION MODULE (DIM) (5/1)

Input signals	Output signals
Via CAN communication (HS-CAN): • From the central electronic module (CEM) with information about which message must be displayed.	**Via CAN communication (HS-CAN):** -

IMMOBILIZER (2005-2012)

DESIGN

GENERAL

The security system in the vehicle is a distributed system which is monitored by the central electronic module (CEM). A number of other units and components are involved for the various functions.

CENTRAL ELECTRONIC MODULE (CEM)

Fig. 36: CEM
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) (4/56) is the master unit for the immobilizer function. The central electronic module (CEM) and engine control module (ECM) are linked to each other through codes. The central electronic module (CEM) is also programmed with a code for each ignition key for the vehicle.

The central electronic module (CEM) transmits commands and signals to the other units in the system. The central electronic module (CEM) also approves the identity of the key. The key is checked via the antenna ring. The antenna ring is installed around the ignition switch. There is a transponder (communication circuit) in the ignition key. The identification code of the transponder is unique. The code must be learned by the central electronic module (CEM) before the key can be used to start the vehicle. This code is learned during installation at the factory. New keys can be added afterwards.

The central electronic module (CEM) controls the relay for the fuel pump and the relay for the starter motor (not applicable to B8444S).

ANTENNA RING

Fig. 37: Antenna Ring
Courtesy of VOLVO CARS CORPORATION

The antenna ring (16/65) is installed around the ignition switch. The antenna ring is used to allow the central electronic module (CEM) to communicate remotely with the ignition key.

The antenna ring comprises a modulation circuit and a communication circuit. The modulation circuit converts signals between the central electronic module (CEM) and the communication circuit. The communication circuit is used to communicate with the key.

When the central electronic module (CEM) activates the antenna ring, a magnetic field is generated around the antenna ring. This magnetic field is converted in the key to an electrical current, which means that the key does not require further electrical supply.

IGNITION KEY

Fig. 38: Identifying Ignition Key
Courtesy of VOLVO CARS CORPORATION

There is a communication circuit in the ignition key, known as a transponder. This circuit is supplied with power from the magnetic field that is formed around the antenna ring when the central electronic module (CEM) activates the antenna ring. Consequently, the transponder is not dependent on a further power supply.

In order for the key to be used in the vehicle, a code in the key must be entered by the central electronic module (CEM). When the vehicle is delivered from the factory, two keys are normally programmed. When a key has been programmed for the central electronic module (CEM), the key is locked and cannot be programmed for another vehicle.

ENGINE CONTROL MODULE (ECM)

Fig. 39: Engine Control Module
Courtesy of VOLVO CARS CORPORATION

The engine control module (ECM) (4/46) controls the ignition system in the vehicle and controls activation of the starter motor via the starter motor relay (applicable to B8444S only). The engine control module (ECM) also grants permission to the central electronic module (CEM), indicating whether the fuel pump is permitted to run when ignition is attempted. These functions are activated once an approved check of the ignition key has been carried out and an identity check has been carried out between the engine control module (ECM) and the central electronic module (CEM) and the result approved.

In order for the engine control module (ECM) to work in the immobilizer system, the control module must be programmed with codes. This takes place for the first time during assembly in the factory, and subsequently takes place in the event the control module is replaced (when downloading software).

DRIVER INFORMATION MODULE (DIM)

Fig. 40: Driver Information Module
Courtesy of VOLVO CARS CORPORATION

The driver information module (DIM) (5/1) receives information from the central electronic module (CEM) about which message is to appear in the display. A message will be displayed if there is a fault in any of the checks run by the system.

DIAGNOSTIC FUNCTIONS

GENERAL

The central electronic module (CEM) is the master unit for the immobilizer. The central electronic module

(CEM) also directly stores diagnostic trouble codes (DTCs) for faults in the immobilizer system. Some other faults can also be stored in the engine control module (ECM).

PROGRAMMING

To increase the security of the immobilizer system, the central electronic module (CEM) and the engine control module (ECM) are linked to each other with codes. Codes must be programmed in when replacing a control module in order for the vehicle to be started. Programming replaced control modules takes place automatically when downloading software into the new control module.

PROGRAMMING IGNITION KEYS

Ignition keys can be added or erased. A maximum of 6 key IDs can be programmed into the central electronic module (CEM). When programming a key, the key is identified to the control module with a code that is stored in the control module memory.

When a key is programmed for the vehicle, the remote control code is also entered if this is to be linked to the vehicle. However, the remote control code has nothing to do with the immobilizer system. If a new key is added to a vehicle, the transponder in the key for this vehicle is locked and consequently cannot be programmed for another vehicle.

The erase function is used when the customer wishes to prevent one or more keys from being used to start the vehicle. The keys may have been stolen and could be traced back to the vehicle.

NOTE: Ignition keys and remote controls are integrated. Therefore the code for the remote control and the transponder must be available when programming. These are programmed at the same time. This means that a key that has been erased can be programmed back into the same vehicle if both these keys are available. The codes can be found on the packaging in which the keys are delivered. If the codes are not available, a new ignition key must be ordered.

Keys are programmed via VIDA vehicle communication.

FUNCTION

THE IMMOBILIZER SYSTEM

The function of the immobilizer is to make the vehicle unusable unless a genuine Volvo key that belongs to the vehicle is used. When the ignition key is turned to position II, a check is performed electronically to ensure that the correct key is being used. If the key is not approved, the engine will not start. The function of the system will not be noticed by the customer as long as an approved key is used and there are no faults.

Deactivation

Fig. 41: Identifying Immobilizer System Communication Links & Components
Courtesy of VOLVO CARS CORPORATION

When the ignition key is turned to position II, the central electronic module (CEM) performs an identity check of the transponder in the key via the antenna ring. In response, the central electronic module (CEM) receives a code from the transponder, which is compared to the codes that are stored in the central electronic module (CEM). If the codes correspond, the key is approved.

At the same time, the central electronic module (CEM) activates the fuel pump and commences an identity check between the central electronic module (CEM) and the engine control module (ECM). The engine control module (ECM) transmits a code to the central electronic module (CEM) and receives a code back. The central electronic module (CEM) also transmits the result of the key check to the engine control module (ECM).

For B8444S, the following applies: if the identity check between the engine control module (ECM) and the central electronic module (CEM), plus the key check, are okay, the engine control module (ECM) will send a command to the central electronic module (CEM) indicating that the fuel pump is permitted to continue running. The engine control module (ECM) will then also activate the starter motor relay and the ignition system.

For other engines, the following applies: if the identity check between the engine control module (ECM) and the central electronic module (CEM), plus the key check, are okay, the engine control module (ECM) will send a command to the central electronic module (CEM) indicating that the fuel pump is permitted to continue running and that the starter motor may be activated. The engine control module (ECM) will then also activate the ignition system.

NOTE: **The engine control module (ECM) allows the fuel pump (FP) to run until the key check and identity check between the engine control module (ECM) and the central electronic module (CEM) is complete. The starter motor will not be activated until the check on the ignition key is complete. Depending on the outcome of these two checks, the engine control module (ECM) will then determine whether the starter motor and fuel pump (FP) should be allowed to continue to operate.**

If either of the checks fails, a message will appear in the display on the driver information module (DIM) and the engine will not start.

Activation

The electronic immobilizer system is activated when the ignition key is turned to position 0 and the engine stops.

For B8444S, the following applies: the engine control module (ECM) will then block activation of the starter motor relay and send a command to the central electronic module (CEM) stating that the fuel pump must not be activated.

For other engines, the following applies: the engine control module (ECM) then sends a command to the central electronic module (CEM) stating that the fuel pump is not permitted to turn over and that the fuel pump must not be activated.

The immobilizer system contains safety functions for preventing the system from being activated in the event the engine should stop while the ignition is still switched on. In this case the engine control module (ECM) will wait for a while before a command is sent to the central electronic module (CEM) indicating that the immobilizer is to be activated. If an attempt is made to start the vehicle within this time, there will be no new communication between the engine control module (ECM) and the central electronic module (CEM).

The immobilizer system will neither be activated if the vehicle is still moving when the engine stops. Similarly, the engine will not stop if the engine control module (ECM) conducts an internal restart while driving.

If the ignition key is turned to position 0 but the key is not removed from the ignition switch, the engine control module (ECM) will wait for a while but then send a command to the central electronic module (CEM) to activate the immobilizer, despite the fact that the key has not been removed from the ignition switch.

Remote-controlled immobilization

Applies for the English, Dutch, and Belgian market. A special version with stricter requirements is available for the Brazilian market. Applies from and incl. structure week 201020.

On certain markets there is a function for remote-controlled immobilization and mobilization. The purpose of the function is to nullify the vehicle's programmed keys in case the vehicle is stolen, for example. The vehicle can be immobilized and mobilized either using Volvo On Call service center or via diagnostic commands in VIDA (Volvo scan tool). For certain markets vehicles can only be mobilized by Volvo On Call service center.

If the vehicle is running when immobilization is requested, the vehicle is immobilized at the next start attempt. Central electronic module (CEM) can, in certain markets, request immobilization if the module detects that Phone module (PHM) does not answer to communication.

The function remote-controlled immobilization is diagnosed by Central electronic module (CEM). Immobilization and mobilization of vehicles via diagnostic commands takes place via Phone module (PHM).

ERROR MESSAGE IN THE DRIVER INFORMATION MODULE (DIM).

Two different error messages may be displayed in the Driver information module (DIM) display for the immobilizer function.

NOTE: Because the information is sensitive to change the exact wording cannot be written here.

1. **Message regarding fault in the system for the immobilizer with reference to the user manual.** The message is displayed when a problem has occurred in communication between the Central electronic module (CEM) and the Engine control module (ECM).
2. **Message regarding prevented start with new attempt request.** The message is displayed if a fault has occurred when reading the transponder in the key.

For further information, see Diagnostic trouble code (DTC) information for the relevant diagnostic trouble codes (DTCs) in the Information manager.

SYSTEM OVERVIEW

GENERAL

Fig. 42: Locating Immobilizer System Components
Courtesy of VOLVO CARS CORPORATION

The immobilizer system increases the level of the vehicle safety system by making it extremely difficult to use the vehicle unless a valid key, which belongs to the vehicle, is used to start it. The identity of the key is checked when the vehicle is started, and if the key is not approved the engine will not start. The customer will not notice this function as long as a valid key is used an no fault occurs.

The immobilizer system includes:

- Central electronic module (CEM)
- Engine control module (ECM)
- Antenna ring
- Driver information module (DIM)
- Remote-controlled immobilization (2010-, option, only certain markets)

Definitions:

Activated system: The system means that the vehicle cannot be started.

Deactivated system: Key check has been carried out and the key has been approved. The system permits the car to start.

SIGNALS

The tables below summarize the input and output signals to the units in the system for the immobilizer. The signal types are divided into directly connected signals, serial communication and controller area network (CAN) communication.

CENTRAL ELECTRONIC MODULE (CEM) (4/56)

Input signals	Output signals
Directly connected: • Input signals from the switches for the different key positions (I, II, III) in the ignition switch.	**Directly connected:** • Starter motor relay, for activation of starter motor (not applicable to B8444S). • Fuel pump (FP) relay for activating the fuel pump (FP).
Via serial communication (LIN): • Antenna ring for communication with the key.	**Via serial communication (LIN):** • Antenna ring for communication with the key.
Via CAN communication (LS-CAN): • Phone module (PHM) (16/60) (only vehicles with remote-controlled immobilization).	**Via CAN communication (LS-CAN):** • Driver information module (DIM) for displaying messages. • Phone module (PHM) (16/60) (only vehicles with remote-controlled immobilization).
Via CAN communication (HS-CAN): • Engine control module (ECM) with information about the engine status and for the immobilizer function.	**Via CAN communication (HS-CAN):** • Engine control module (ECM) for communication and checking identity.

ANTENNA RING (16/65)

Input signals	Output signals
Via serial communication: • Central electronic module (CEM) for communication with the key.	**Via serial communication:** • Central electronic module (CEM) for communication with the key.

ENGINE CONTROL MODULE (ECM) (4/46)

Input signals	Output signals
Directly connected: -	**Directly connected:** • Starter motor relay, for activation of starter motor (applicable to B8444S only).
Via CAN communication (HS-CAN):	**Via CAN communication (HS-CAN):** • Information about the engine status

• Communication with the central electronic module (CEM) during start attempts.	• Communication with the central electronic module (CEM) during start attempts.

DRIVER INFORMATION MODULE (DIM) (5/1)

Input signals	Output signals
Via CAN communication (LS-CAN): • From the central electronic module (CEM) with information about which message must be displayed.	**Via Controller Area Network (CAN) communication:** -

PHONE MODULE (PHM) (16/60)

Input signals	Output signals
Via Controller Area Network (CAN) communication: • From Central electronic module (CEM) (4/56) with information on remote-controlled immobilization.	**Via Controller Area Network (CAN) communication:** • To Central electronic module (CEM) (4/56) with information on remote-controlled immobilization.

INFOTAINMENT CONTROL MODULE (ICM) (2003-2006)

DESIGN

GENERAL

The infotainment control module (ICM) consists of the following replaceable components:

- display/printed circuit board
- left-hand keypad
- right-hand keypad
- remote controls.

These units can be replaced individually.

DISPLAY/PRINTED CIRCUIT BOARD

Fig. 43: View of Information Display
Courtesy of VOLVO CARS CORPORATION

The display shows information about the function which is active. It also displays information when selecting functions and preferences for the infotainment system.

The display is connected via a cable direct to the printed circuit board. They are integrated in the same unit.

There are two display versions, standard and graphic. The standard display has three rows of text and a field with fixed symbols. The graphic display consists of a field with 128*64 pixels.

The printed circuit board has inputs for the display, keypads as well as in and outputs for power supply, ground, the CAN and MOST networks. The processor for the infotainment control module (ICM) is on the printed circuit board. Therefore the printed circuit board contains all the functionality and logic for the infotainment control module (ICM). The printed circuit board also stores the software for the infotainment control module (ICM). The control module must be reprogrammed when replacing the display and/or printed circuit board.

There are diagnostics for the power for the display. There are diagnostics for the printed circuit board.

LEFT-HAND KEYPAD

Fig. 44: Identifying Left-Hand Keypad
Courtesy of VOLVO CARS CORPORATION

The left-hand keypad unit is on the left-hand side of the infotainment control module (ICM). The keypad is connected via a cable directly to the printed circuit board. The keypad unit has the following buttons:

- ON/OFF button (POWER)
- buttons for direct access to the CD player and radio
- buttons for searching on the CD player and radio
- numeric buttons for the carphone, CD selection (CD changers only) and preprogrammed radio stations
- a knob for the volume control
- an infrared receiver for remote control.

The buttons are connected in button circuits. When a button is pressed the circuit closes. The infotainment control module (ICM) determines which button is pressed by the voltage level of the input signal from the circuit. The table below outlines which buttons are in the different circuits:

Button circuit	Button			
Button circuit 1	>>|	AM/FM	|<<	CD
Button circuit 2	*	7	4	1
Button circuit 3	0	8	5	2
Button circuit 4	#	9	6	3
Power button	POWER			

There are diagnostics for the left-hand keypad unit.

RIGHT-HAND KEYPAD

Fig. 45: Identifying Right-Hand Keypad
Courtesy of VOLVO CARS CORPORATION

The right-hand keypad unit is on the right-hand side of the infotainment control module (ICM). The keypad is connected via a cable directly to the printed circuit board. The keypad unit has the following buttons:

- button for sound control (bass, treble etc)
- button for carphone on/off (only for cars with carphones)

- button for selecting the function, can be programmed by the user
- buttons for the carphone and menu control
- SIM card holder (only for cars with carphones)
- button to open the CD tray
- knob to select the source.

The buttons are connected in button circuits. When a button is pressed the circuit closes. The infotainment control module (ICM) determines which button is pressed by the voltage level of the input signal from the circuit. The table below outlines which buttons are in the different circuits:

Button circuit	Button			
Button circuit 1	EXIT	PHONE	ENTER	MY KEY
Button circuit 2	CD eject	Down	Up	
Button circuit 5	Sound			

The SIM card holder is connected via a directly connected cable to the phone module (PHM). It is not connected to the infotainment control module (ICM).

There are diagnostics for the right-hand keypad unit.

REMOTE CONTROLS

Fig. 46: Identifying Remote Controls
Courtesy of VOLVO CARS CORPORATION

There are two different remote controls for the infotainment system. One is used for audio, radio and TV remote control. The other is used for remote control of the navigation system. The remote controls can be used to activate most of the functions which can be controlled via the keypad units on the infotainment control module (ICM) and via the buttons on the steering wheel.

The remote controls transmit infrared signals to the receiver unit which is in the left-hand keypad on the infotainment control module (ICM). The signals then go via the directly connected cable to the printed circuit board which controls the selected function.

DIAGNOSTIC FUNCTIONS

GENERAL

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault.

This control module can store up to six diagnostic trouble codes (DTCs), the three first and the three latest.

Should a fault disappear for any reason after being permanently stored in the control module as a diagnostic trouble code (DTC), the information remains stored in the control module.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function. The on-board diagnostic (OBD) system can identify 44 different faults in the infotainment control module (ICM). These are stored as diagnostic trouble codes (DTCs). This function can also be used to read off whether the fault is still present (permanent) or whether it has now ceased (intermittent) after the diagnostic trouble code (DTC) has been stored. Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF INPUT AND OUTPUT SIGNALS

This function can be used to read off the status or value of parameters. The presentation of the status or value can be obtained graphically or digitally. For further information about the different parameters, see **DESCRIPTION OF PARAMETERS** .

ACTIVATING COMPONENTS AND FUNCTIONS

This function can be used to activate components and functions which affect the infotainment control module (ICM). For further information about activations, see **DESCRIPTION OF ACTIVATIONS** .

READING OFF STATIC DATA

This function allows programmed data to be read off or data such as customer parameters to be programmed in.

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)

- software P/N
- diagnostic software P/N.

READING OFF EXTENDED FAULT-TRACING INFORMATION

This function can be used to read parameters, status identifiers and counters stored at the same time as a diagnostic trouble code (DTC). These are called frozen values.

For further information, see **DESCRIPTION OF EXTENDED DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION** .

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the infotainment control module (ICM). When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

The infotainment control module (ICM) is in the center console. The control module needs to be removed from the center console to be replaced.

Parts of the infotainment control module (ICM) can be replaced. The control module must be reprogrammed when replacing the display and/or printed circuit board. The display/printed circuit board can be removed from the infotainment control module (ICM) after the front panel has been removed.

The MOST network is used for a total software reload.

FUNCTION

SECURITY ON MOST

Fig. 47: Control Modules On The MOST Network
Courtesy of VOLVO CARS CORPORATION

The Security on MOST function is intended to prevent non-approved control modules from being installed in the car for the infotainment system. This is to prevent the theft of units.

This function is controlled by the infotainment control module (ICM) (16/1). The infotainment control module (ICM) checks the serial number of all the control modules in the MOST network and compares these with a stored list. The infotainment control module (ICM) retrieves data about the serial number of the control modules via the MOST network. The infotainment control module (ICM) then compares this information with the stored serial numbers.

If a control module is not in the stored list, it is disconnected from the MOST network and the functionality of this control module is blocked. This means that control modules in the MOST network cannot be transferred from one car to another.

If a control module which is in the stored list gives an incorrect response, a diagnostic trouble code (DTC) is stored in the infotainment control module (ICM).

SYSTEM OVERVIEW

INFOTAINMENT CONTROL MODULE (ICM)

Fig. 48: Identifying Infotainment Control Module (ICM)
Courtesy of VOLVO CARS CORPORATION

The infotainment control module (ICM) acts as a gateway between the CAN and MOST networks. It also acts as the master control module in the MOST network and checks the other control modules. The infotainment control module (ICM) consists of the following components:

- display/printed circuit board
- left-hand keypad
- right-hand keypad
- remote controls (up to two units).

The infotainment control module (ICM) controls functions run on the MOST network via its user interface. The command is transmitted from the infotainment control module (ICM) to the other control modules in the network. These implement the requested functions, for example sound playback, changing sound sources and

radio settings. The infotainment control module (ICM) also controls the Security on MOST function.

The infotainment control module (ICM) is in the center console. The control module is removed from the center console for replacement. The keypad unit and display/printed circuit board can be replaced separately. These are removed by detaching the front panel on the infotainment control module (ICM).

The infotainment control module (ICM) communicates with other control modules via CAN and MOST communication. MOST communication is via a fiber optic communication link.

The control module checks activations and input and output signals via an integrated diagnostic system. A diagnostic trouble code (DTC) is stored if the infotainment control module (ICM) detects a fault.

Any diagnostic trouble codes (DTCs) are stored in the control module memory. This information can be read off using VIDA via the data link connector (DLC) in the car.

A simple way to ensure that the infotainment control module (ICM) is powered and grounded is to check that the button lighting on the infotainment control module (ICM) is lit when the ignition key is in position I or II. The infotainment control module (ICM) is powered and grounded if the button lighting activates.

SIGNALS

The following table summarizes the input signals to and output signals from the infotainment control module (ICM). The signal types are divided into infrared signals, MOST communication and CAN communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Via infrared signals: • Remote control.	**Via infrared signals:**
Via MOST communication: • Antenna module (ATM) (16/110) • Audio module (AUD) (16/105) • Multimedia module (MMM) (16/108) • MD module (MP1) (16/107) • CD module (MP2) (16/106) • Phone module (PHM) (16/60) • Subwoofer module (SUB) (16/79).	**Via MOST communication:** • Antenna module (ATM) (16/110) • Audio module (AUD) (16/105) • Multimedia module (MMM) (16/108) • MD module (MP1) (16/107) • CD module (MP2) (16/106) • Phone module (PHM) (16/60) • Subwoofer module (SUB) (16/79).
Via Controller Area Network (CAN) communication: • Accessory electronic module (AEM) (4/78) • Brake control module (BCM) (4/16) • Central electronic module (CEM) (4/56) • Engine control module (ECM) (4/46)	**Via Controller Area Network (CAN) communication:** • Central electronic module.

• Rear electronic module (REM) • Supplemental Restraint System Module • Steering wheel module.	

Fig. 49: Identifying Volvo Component Designations

INFOTAINMENT CONTROL MODULE

DESIGN

GENERAL

The infotainment control module consists of the following replaceable components:

- display/printed circuit board
- left-hand keypad
- right-hand keypad
- remote controls.

These units can be replaced individually.

DISPLAY/PRINTED CIRCUIT BOARD

Fig. 50: View of Information Display
Courtesy of VOLVO CARS CORPORATION

The display shows information about the function which is active. It also displays information when selecting functions and preferences for the infotainment system.

The display is connected via a cable direct to the printed circuit board. They are integrated in the same unit.

There are two display versions, standard and graphic. The standard display has three rows of text and a field with fixed symbols. The graphic display consists of a field with 128*64 pixels.

The printed circuit board has inputs for the display, keypads as well as in and outputs for power supply, ground, the CAN and MOST networks. The processor for the infotainment control module is on the printed circuit board. Therefore the printed circuit board contains all the functionality and logic for the infotainment control module. The printed circuit board also stores the software for the infotainment control module. The control module must be reprogrammed when replacing the display and/or printed circuit board.

There are diagnostics for the power for the display. There are diagnostics for the printed circuit board.

LEFT-HAND KEYPAD

Fig. 51: Identifying Left-Hand Keypad
Courtesy of VOLVO CARS CORPORATION

The left-hand keypad unit is on the left-hand side of the infotainment control module. The keypad is connected via a cable directly to the printed circuit board. The keypad unit has the following buttons:

- ON/OFF button
- buttons for direct access to the CD player and radio
- buttons for searching on the CD player and radio
- numeric buttons for the carphone, CD selection and preprogrammed radio stations
- a knob for the volume control
- an infrared receiver for remote control.

The buttons are connected in button circuits. When a button is pressed the circuit closes. The infotainment control module determines which button is pressed by the voltage level of the input signal from the circuit. The table below outlines which buttons are in the different circuits.

Button circuit	Button			
Button circuit 1				
Button circuit 2				
Button circuit 3				
Button circuit 4				
Power button				

There are diagnostics for the left-hand keypad.

RIGHT-HAND KEYPAD

Fig. 52: Identifying Right-Hand Keypad
Courtesy of VOLVO CARS CORPORATION

The right-hand keypad unit is on the right-hand side of the infotainment control module (ICM). The keypad is connected via a cable directly to the printed circuit board. The keypad unit has the following buttons:

- button for sound control
- button for carphone on/off
- button for selecting the function, can be programmed by the user
- buttons for the carphone and menu control
- SIM card holder
- button for CD ejection
- knob to select the source.

The buttons are connected in button circuits. When a button is pressed the circuit closes. The infotainment control module determines which button is pressed by the voltage level of the input signal from the circuit. The table below outlines which buttons are in the different circuits.

Button circuit	Button			
Button circuit 1				
Button circuit 2	CD eject	Down	Up	
Button circuit 5	Sound			

The SIM card holder is connected via a directly connected cable to the phone module (PHM). It is not connected to the infotainment control module (ICM).

There are diagnostics for the right-hand keypad.

REMOTE CONTROLS

Fig. 53: Identifying Remote Controls
Courtesy of VOLVO CARS CORPORATION

There are two different remote controls for the infotainment system. One is used for audio, radio and TV remote control. The other is used for remote control of the navigation system.

The remote controls can be used to activate most of the functions which can be controlled via the keypad units on the infotainment control module (ICM) and via the buttons on the steering wheel.

The remote controls transmit infrared signals to the receiver unit which is in the left-hand keypad on the infotainment control module (ICM). The signals then go via the directly connected cable to the printed circuit board which controls the selected function.

DIAGNOSTIC FUNCTIONS

GENERAL

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. This control module can store up to 6 diagnostic trouble codes (DTCs), the three first and the three latest.

If a fault disappears for any reason after the diagnostic trouble code (DTC) has been permanently stored in the control module, information about the fault remains in the control module.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function. The on-board diagnostic (OBD) system can identify 41 different faults in the infotainment control module (ICM). These are stored as diagnostic trouble codes (DTCs). This function can also be used to read off whether the fault is still present (permanent) or whether it has now ceased (intermittent) after the diagnostic trouble code (DTC) has been stored.

Diagnostic trouble codes can only be erased once all the diagnostic trouble codes have been read out at least once.

READING OFF THE PARAMETERS

This function is used to read the status or value of parameters. The status or value can be presented digitally.

ACTIVATING COMPONENTS AND FUNCTIONS

This function can be used to activate components/functions which affect the infotainment control module (ICM).

READING OFF STATIC DATA

This function allows programmed data to be read off or data such as customer parameters to be programmed in.

READING OFF THE CONTROL MODULE IDENTIFICATION

The diagnostic tool identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N

READING OFF EXTENDED FAULT-TRACING INFORMATION

This function can be used to read out parameters, identify status and counts stored at the same time as a diagnostic trouble code (known as frozen values).

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the infotainment control module (ICM). When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

The infotainment control module (ICM) is in the center console. The control module must be removed from the center console to be replaced.

Parts of the Infotainment control module (ICM) can be replaced. The control module must be reprogrammed when replacing the display and/or printed circuit board.

The display/printed circuit board can be removed from the infotainment control module (ICM) after the front panel has been removed.

Select reload of CAN network for a total reload of the software in the vehicle.

FUNCTION

SECURITY ON MOST

Model year 2007 and 2008

Fig. 54: Control Modules On The Most Network
Courtesy of VOLVO CARS CORPORATION

Model year 2009-2010

Fig. 55: Identifying MOST Network Control Modules (Up To Eight)
Courtesy of VOLVO CARS CORPORATION

Model year 2011

Fig. 56: Control Modules On The Most Network
Courtesy of VOLVO CARS CORPORATION

The function Security on MOST prevents unapproved control modules in the infotainment system from being installed in the vehicle. This is to prevent the theft of units.

The function is controlled by the infotainment control module (ICM). The infotainment control module (ICM) checks the serial numbers of all the control modules in the MOST network and compares these with a stored list. The infotainment control module (ICM) retrieves data about the serial number of the control modules via the MOST network. The infotainment control module (ICM) compares the information with the stored serial numbers.

If a control module is not in the stored list, it is disconnected from the MOST network and the functionality of this control module is blocked. This means that control modules in the MOST network cannot be moved from one vehicle to another.

A diagnostic trouble code (DTC) is stored in the infotainment control module (ICM) if a control module in the stored list gives the incorrect response.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 57: Identifying Infotainment Control Module

Courtesy of VOLVO CARS CORPORATION

The infotainment control module (ICM) acts as a gateway between the CAN and MOST network. It also acts as the master control module in the MOST network and checks the other control modules.

The infotainment control module (ICM) consists of the following components:

- display/printed circuit board
- left-hand keypad
- right-hand keypad
- remote controls (up to two).

The infotainment control module (ICM) controls functions run on the MOST network via its user interface. The command is transmitted from the infotainment control module (ICM) to the other control modules in the network. These implement the requested functions, for example sound playback, changing sound sources and radio settings.

The infotainment control module (ICM) also controls the Security function on MOST.

The infotainment control module (ICM) is in the center console. The control module is removed from the center console for replacement.

The keypad unit and display/printed circuit board can be replaced separately. These are removed by detaching the front panel on the infotainment control module (ICM).

The Infotainment control module (ICM) communicates with other control modules, via CAN communication and via MOST communication.

MOST communication is via a fiber optic communication link.

The control module checks activations and input and output signals via an integrated diagnostic system. A diagnostic trouble code (DTC) is stored if the infotainment control module (ICM) detects a fault.

Any diagnostic trouble codes (DTCs) are stored in the control module memory. This information can be read off using the diagnostic tool via the data link connector (DLC) in the vehicle.

A simple way to ensure that the infotainment control module (ICM) is powered and grounded is to check that the button lighting on the infotainment control module (ICM) is lit when the ignition key is in position I or II.

If the button lighting is activated, the Infotainment control module (ICM) is powered and grounded.

SIGNALS

The table below summarizes the input signals to and output signals from the Infotainment control module (ICM). The signal types are divided into infra-red signals (IR), MOST communication and controller area network (CAN) communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Via MOST communication: • Audio module (AUD) (16/105) • Multimedia module (MMM) (16/108) • Phone module (PHM) (16/60) • Subwoofer module (SUB) (16/79) (up to and incl. model year 2008) • Integrated audio module (IAM) (16/1) • Remote Digital Audio Receiver (RDAR) (16/145) • Global positioning system module (GPS) (16/139) (model year dependent) • Accessory USB unit (AUU) (4/124) (structure week 200709 - 201020) • Bluetooth phone module (BPM) (16/147) (from and including structure week 201020)	**Via MOST communication:** • Audio module (AUD) (16/105) • Multimedia module (MMM) (16/108) • Phone module (PHM) (16/60) • Subwoofer module (SUB) (16/79) (up to and incl. model year 2008) • Integrated audio module (IAM) (16/1) • Remote Digital Audio Receiver (RDAR) (16/145) • Global positioning system module (GPS) (16/139) (model year dependent) • Accessory USB unit (AUU) (4/124) (structure week 200709 - 201020) • Bluetooth phone module (BPM) (16/147) (from and including structure week 201020)

INTEGRATED AUDIO MODULE (IAM) (2007-2012)

DESIGN

CONTROL MODULE

Fig. 59: Identifying Integrated Audio Module (IAM)
Courtesy of VOLVO CARS CORPORATION

The integrated audio module (IAM) is mounted in the center console. It is integrated with the audio unit and they are replaced together.

The infotainment control module (ICM) display shows the current status of the integrated audio module (IAM).

Integrated audio module (IAM) has an integrated amplifier with a power output of 4x20 W.

The two other versions do not have an integrated amplifier, they use the Audio module (AUD) as an amplifier.

ANTENNAS

Fig. 60: Identifying Antennas
Courtesy of VOLVO CARS CORPORATION

The integrated audio module (IAM) is connected to an AM and FM antenna system. This consists of a main antenna, an FM sub-antenna and an AM antenna. The antennas are connected to an antenna amplifier. The antenna amplifier has two channels: one for the FM main antenna and the AM antenna and another for the FM sub-antenna.

Both channels are connected to the integrated audio module (IAM) via a coaxial cable.

The connection for the sub antenna is used to supply power to the antenna amplifier. If the Multimedia module (MMM) is in the vehicle (does not apply to the USA), the sub antenna is connected from the antenna amplifier to the Integrated Audio Module (IAM) via the Multimedia module (MMM).

REMOTE CONTROL

Fig. 61: Identifying Remote Control On Steering Wheel
Courtesy of VOLVO CARS CORPORATION

Remote control via a steering wheel keypad is available as either an option or as standard equipment depending on the market. The keypad is located on the right side of the steering wheel and is connected to the steering wheel module (SWM) via serial communication.

LOUDSPEAKERS

Fig. 62: Identifying Loudspeakers
Courtesy of VOLVO CARS CORPORATION

The integrated audio module for has 4 speakers directly connected to the control module:

- one pair of front loudspeakers
- one pair of rear loudspeakers.

Impedance for each speaker is 4 ohms.

For the two other versions with the integrated audio module, the speakers are connected to the audio module (AUD).

DIAGNOSTIC FUNCTIONS

GENERAL

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

If the control module detects a fault, a diagnostic trouble code is generated. The control module can store up to 10 trouble codes. A fault that is detected during the most recent operating cycle is defined as permanent. Other faults that are detected are defined as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF THE CONTROL MODULE IDENTIFICATION

The control module can be identified by means of reading off a number of codes.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

Software can be downloaded to the integrated audio module (IAM). When software is ordered, the vehicle' software and hardware is compared to Volvo's central database. If they are compatible, the software is downloaded to the system.

If the comparison between the car and Volvo's central database does not correspond, then the database is updated with the vehicle's configuration. When this is complete the software is downloaded.

If the integrated audio module (IAM) is replaced, its unique serial number is checked by the infotainment system (ICM). If the serial number is incorrect, the installed integrated audio module (IAM) does not work.

If a problem arises after software download and the control module does not work, try switching the ignition off and on.

Select the MOST network for a total download of software to the vehicle.

FUNCTION

AUDIO UNIT

Fig. 63: Control Modules On The MOST Network
Courtesy of VOLVO CARS CORPORATION

The integrated audio module (IAM) functions as a stereo system in the vehicle and is connected to other control modules on the MOST network.

Integrated audio module (IAM) controls settings for:

- Volume
- Bass
- Treble
- Balance
- Fader
- Equalizer

The Integrated Audio Module compensates the sound amplitude depending on the vehicle speed and has automatic loudness.

The Integrated Audio Module manages playback of compressed music formats from cd.

Support available for following formats:

-
-

The integrated audio module (IAM) can play music via the AUX input.

The AUX input is located in the tunnel console.

From structure week 200848, there is support for playback of music via a USB/iPod-connection in the glove compartment (does not apply to Performance or CD-changers for 6 discs). Support available for the following formats:

- mp3
- wav
- wma

From structure week 200848, there is support for reception of digital HD-radio (does not apply to Performance or CD-changers for 6 discs).

HD radio is transmitted digitally on the AM respectively FM wavelength in USA. The Integrated Audio Module (IAM) automatically switches to digital HD radio reception if there is a current frequency and if the function for HD-radio is highlighted in the user menu.

When the Integrated Audio Module (IAM) receives digital HD radio, a symbol appears for HD radio in the Infotainment control module (ICM).

The integrated audio module (IAM) lowers the volume from the current source when the control module receives other audio information, such as indication from the parking assistance function or phone call.

If the vehicle is equipped with a Multimedia module (MMM), voice information is played via the existing speakers.

REMOTE CONTROL

Fig. 64: Identifying Steering Wheel Remote Control

Courtesy of VOLVO CARS CORPORATION

Remote control on the steering wheel (standard/option) is directly connected to the Steering wheel module (SWM) via serial communication. Volume (reduce-increase) and selection of pre-programmed radio stations can be operated via remote control. During CD or USB/iPod playback, the buttons work as track selection.

The Steering wheel module (SWM) (3/254) communicates via LIN with the Central electronic module (CEM) (4/56) and on to the Infotainment control module (ICM) (16/94) via the CAN network.

The Infotainment control module (ICM) transmits the signals on to the Integrated Audio Module (IAM) (16/1) via the MOST network.

AUDIO REMOTE CONTROL (OPTION)

Fig. 65: Viewing Wireless Remote Control
Courtesy of VOLVO CARS CORPORATION

As an option, remote control can occur from a separate wireless remote control. Volume (increase-reduce) can be controlled and pre-programmed radio stations can be selected via remote control.

During CD or USB/iPod playback the buttons on the remote control work as track selection and during CD playback via the CD exchanger, the remote control can also be used to select CD. A certain frequency can also be searched for, radio stations stored in program locations (Presets), Autostore used and SOURCE selected.

SUPPORT FOR USB ACCESSORIES

SUPPORT FOR USB ACCESSORIES

General

The Integrated Audio Module only supports USB accessories with the profile. Both USB 1.1 and USB 2.0 are supported.

Hard disks are not supported but can still work if the power consumption is less than 500 mA.

USB hubs are not supported.

The charging of USB accessories is not supported but can still function if the USB accessory supports 5 volt charging and if the power consumption is less than 500 mA.

USB memories

The Integrated Audio Module supports FAT16 from and including 128 MB and upwards and FAT32 from and including 256 MB and upwards.

Permitted file size: 1 kB to 2 GB.

Maximum permitted number of files: 64000

Maximum permitted number of folders: 500

Maximum permitted folder depth: 8

SUPPORT FOR CELLPHONES AND OTHER ACCESSORIES

SUPPORT FOR CELLPHONES AND OTHER ACCESSORIES

The Integrated Audio Module supports all cellphones with the profile with files in file format FAT32 and FAT16. The cellphone needs to be configured to before use.

For USB accessories with extra functions such as U3 (Sandisk) it is recommended that the extra functions are uninstalled before use.

iPod support

The Integrated Audio Module (IAM) supports playback from iPods with a maximum of 64000 files. No limit for number of folders.

SUPPORT FOR CDS

SUPPORT FOR CDS

General:

- Diameter: 120 ±0.3 mm.
- Thickness: 1.2 +0.3/-0.1 mm.
- Distortion: ±0.5 mm.

Discs with a diameter of 8 cm are not supported and will be ejected if attempts are made to play them.

Disc types

CD Audio, CD-R Audio, CD-RW and CD-ROM.

Disc format

CD Audio:

Maximum permitted number of tracks: 99

Maximum permitted number of sections: 99

CD-ROM:

Maximum permitted number of files: 255

No limit to number of folders or folder depth

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 66: Identifying Integrated Audio Module (IAM)
Courtesy of VOLVO CARS CORPORATION

The integrated audio module (IAM) handles functions for:

- Radio reception (AM and FM)
- CD playback
- AUX playback
- RDS reception

The integrated audio module (IAM) communicates with directly connected components as well as with other control modules and components via the MOST network, which is a fiber-optic communication network.

The integrated audio module (IAM) is a slave module on the MOST network. The infotainment control module (ICM) is the master module.

The integrated audio module (IAM) is mounted in the center console. It is integrated with the audio unit and

they are replaced together.

In order to function in the MOST network, the infotainment control module (ICM) checks that the integrated audio module (IAM) has a correct serial number. If the number is incorrect, the integrated audio module (IAM) does not work.

The integrated audio module is available in three versions:

- **Integrated amplifier,** with integrated radio, cd player and internal amplifier.
- **Without integrated amplifier,** with integrated radio and cd player. The version requires an external amplifier, Audio module (AUD). Subwoofer, Subwoofer module (SUB) available as accessory.
- **Without integrated amplifier,** with integrated radio and cd changer. The version requires an external amplifier, Audio module (AUD). Subwoofer, Subwoofer module (SUB) available as accessory.

RDS reception (Radio Data System) is possible with FM broadcasts (market-dependent). The system is called RBDS (Radio Broadcast Data System) in USA.

From structure week 200848, versions with support for reception of digital HD-radio are available. Only applies to the USA market.

The Integrated Audio Module manages playback of compressed music formats from cd.

Support available for following formats:

-
-

From structure week 200848, there is support for playback of music via a USB/iPod-connection in the glove compartment (does not apply to Performance or CD-changers for 6 discs). Support available for the following formats:

- mp3
- wav
- wma

The speakers that are installed in the front and rear doors are connected to the control module or an external amplifier, Audio module (AUD).

The Integrated Audio Module (IAM) checks internal components, executed activations and input/output signals via its integrated diagnostics. If the control module detects a fault, a diagnostic trouble code is generated. Any diagnostic trouble codes are stored in the control module memory. The information can be read via the data link connector in the vehicle.

SIGNALS

The table below summarizes the input signals to and output signals from the integrated audio module (IAM).

Signal type is divided into directly connected signals and MOST communication. The illustration below depicts the same information plus Volvo's component designation.

Input signals	Output signals
Directly connected: • Power supply • Ground • Antenna. AM and FM signal via antenna amplifier (16/16) • AUX input (17/40) • USB/iPod input (17/42)	**Directly connected:** • Loudspeaker (16/3-6), x 4 • Phantom feed antenna amplifier (16/16) • USB/iPod input (17/42)
MOST communication: • Infotainment control module (ICM) (16/94)	**MOST communication:** • Infotainment control module (ICM) (16/94) • Audio module (AUD) (16/105) • Subwoofer module (SUB) (16/79)

INTERIOR (2003-2012)

INTERIOR

DASHBOARD/SEATS

Fig. 68: Identifying Seat Configuration
Courtesy of VOLVO CARS CORPORATION

Dashboard/Center console

The dashboard consists of a single unit.

The center console is detachable. The rear section can be detached and removed.

Seats

The XC90 is available with two different seat formats, five seater and seven seater.

Five seater

The second row of seats in the five seater version splits into three parts, 40-20-40 (%).

The backrests can be folded down individually. When the backrests are folded down, the seat moves downwards to give a flat cargo floor.

Seven seater

The seven seater version has a third row with two separate seats. The second row of seats can be moved and adjusted individually from front to rear.

To access the third row of seats, lift the control on the outer backrest on the second row of seats. The backrest folds forwards while the seat moves forward.

To fold the backrest on the third row of seats, use the control at the front edge of the seat cushions, beside the side panels. When the control is lifted, the seat cushions slide backwards and the backrests then fold.

If the center seat has an integrated child seat, the seat can be slid forward to the front position to remove the rear section of the center console. This gives occupants in the front seats better access to the child.

LIGHTING (2003-2012)

LIGHTING

FRONT LIGHTING

Fig. 69: Identifying Front Lighting
Courtesy of VOLVO CARS CORPORATION

1. Fog lamps

2. Motor, headlamp range adjustment
3. Side turn signal flashers
4. Sidemarker lamps
5. Low beam
6. Parking lamps
7. Turn signal lamps
8. High beam.

Front lighting

Unique to this design is that the entire headlamp housing can be removed. The entire headlamp housing is removed to replace the headlamp and bulbs.

- The lens is made of clear plastic
- There are separate reflectors for high and low beam
- Integrated turn signal lamps and parking lamps
- Headlamp range adjustment is as before.

Bi-xenon

Available as a factory option.

Fog lamps

Positioned in the bumper.

TAIL LAMPS

Fig. 70: View of Tail Lamps
Courtesy of VOLVO CARS CORPORATION

1. Stop lamp (LED)
2. License plate lighting
3. Fog tail lamp (Parking lamps, USA)
4. Stop lamps
5. Back-up (reversing) lamp
6. Parking lamps (Fog tail lamp, USA)
7. Turn signal lamps.

Tail lamps

A new design where the entire tail lamp can be detached when changing bulbs.

- High mounted stop lamp in the spoiler
- The fog tail lamp is integrated in the bumper. (Parking lamps, USA)
- A new type of bulb has been introduced. Two wire (4/P21W).

LIN - LOCAL INTERCONNECT NETWORK (2003-2012)

CONTROL MODULES THAT COMMUNICATE VIA LIN

Fig. 71: Control Modules That Communicate Via LIN
Courtesy of VOLVO CARS CORPORATION

NOTE: **The illustration above and the table below is an example that shows model year 2007. All other information in the document is general and applies to all model years.**

Control module	Name/ Function	Connected to/Master node	Other
ACM	Alternator control module (ACM) Controls charge regulation of the battery.	Engine control module (ECM). Also diagnosed by the Central electronic module (CEM).	
AQS	Air quality sensor (AQS) Measures the particle content in the air into the climate system.	Climate control module (CCM)	The Climate control module (CCM) uses this signal as a basis for control of the damper for recirculation.
CPM	Combustion preheater module (CPM)	Central electronic module (CEM)	

	Petrol driven engine and passenger compartment heater.		
DMM	Damper motor module (DMM) Regulates the air flow in the passenger compartment, temperature between the right and left sides as well as recirculation.	Climate control module (CCM)	The number of damper motors varies depending on the equipment level and whether the vehicle is right or left hand drive.
GSM	Gear selector module (GSM) Provides input signals to the Transmission control module (TCM), about the position of the gear shift.	Transmission control module (TCM)	Vehicles with automatic transmission only.
ISM	Inclination sensor module (ISM) Detects changes to the vehicle incline when the alarm is activated.	Rear electronic module (REM)	
LCM	Left camera module (LCM)	Driver door module (DDM) or Passenger door module (PDM) depending on whether the vehicle is right or left hand drive.	Component in the BLIS system.
LSM	Light switch module (LSM) Sends signals to the Central electronic module (CEM) concerning settings for the exterior and instrument lighting.	Central electronic module (CEM)	
OWS	Occupant weight sensor (OWS) Used as an input signal to indicate deactivation of the front passenger airbag.	Supplemental restraint system module (SRS)	
RCM	Right camera module (RCM)	Driver door module (DDM) or Passenger door module (PDM) depending on whether the vehicle is right or left hand drive.	Component in the BLIS system.
RSM	Rain sensor module (RSM) Detects whether there is water on the windscreen.	Upper electronic module (UEM)	Used to control the automatic wiper function.
SCM	Siren control module (SCM) Controls the siren function.	Upper electronic module (UEM)	
SHM	Seat heating module (SHM), driver's side and Seat heating module (SHM), passenger-	Climate control module (CCM)	

	side.		
SRM	Sun roof module (SRM) Control sun roof functionality.	Upper electronic module (UEM)	
SWSL	Steering wheel switch left (SWSL)	Central electronic module (CEM)	Concerns the steering wheel buttons for control of radio and telephone functions.
SWSR	Steering wheel switch right (SWSR)	Central electronic module (CEM)	Concerns the steering wheel buttons for control of radio and telephone functions.

ERROR MANAGEMENT IN THE LOCAL INTERCONNECT NETWORK (LIN)

ELECTRICAL FAULTS

The communication circuits in the LIN control modules cannot detect electrical faults on the wire. However the master node continuously reads back the last message it sent itself to check that it has been sent correctly over the LIN bus.

Should the master node discover that the message last read back is incorrect, for example if the signal wire has been short-circuited to voltage or ground, the master node can set the diagnostic trouble code (DTC) denoting the message has not been sent correctly.

COMMUNICATION FAILURE

The master node on a LIN bus sends out messages at specific time intervals.

The master node on the LIN bus in question knows which type of response that a particular slave node shall send back for a specific message sent from the master node. If the master mode does not receive this response, it can set the diagnostic trouble code for failed communication with the slave node in question.

FAULTS DISCOVERED BY SLAVE NODES

Control modules that use LIN communication can have integrated diagnostics exactly as the control modules on CAN. However, it is the Master node to which the slave node is connected that stores the diagnostic trouble codes for faults that the slave node discovers.

Information about discovered faults in the slave nodes is sent in the messages to the master node.

Each slave node on a LIN bus can be seen as an extension of the master node's own connections. In most cases it is also the master node that makes evaluations whether the diagnostic trouble code (DTC) can be set or not.

SOFTWARE DOWNLOADING

The control modules used as slave nodes on Volvo's LIN buses are supplied preconfigured and with that programmed for a specific behaviour.

Volvo does not use software downloading via LIN. However a new configuration file for a LIN bus can be downloaded to the master node that controls communication on a LIN bus, on condition that the master mode is connected to the vehicle's CAN network.

Accordingly, new slave nodes can be added to an existing LIN bus.

LIN (LOCAL INTERCONNECT NETWORK)

GENERAL

LIN (Local Interconnect Network) is a standardised protocol for serial communication on a single wire between a master and several slave nodes.

The LIN protocol supports Multiplex communication, which means several nodes can communicate on the same wire without disturbing each other.

LIN was developed, by a consortium of automotive manufacturers, at the end of the 90s in order to build a network for data exchange over short distances at a low cost. The development of the LIN standard is ongoing and Volvo plays an active part in this work.

LIN is adapted for one master and up to 16 slave nodes on each communication bus.

More nodes are possible, but several communication buses can in these instances be connected together via the master node. The master node can also make up an interface to other types of communication buses, for example, CAN or MOST.

LIN is bidirectional, (two way half duplex) which means information can be sent in both directions. However only one control module at a time can send information. The level on the bus wire is normally high (approx 13 V) via a pull-up resistance, but is taken down to a low level (approx 1 V) when one of the nodes on the bus transmits.

The LIN protocol is a supplement to CAN. LIN is a less expensive alternative to CAN and is used where the transfer rate and performance is not as critical.

Besides a reduction in the number of wires, LIN is adapted for more basic communications circuits, which means the internal clock circuit in a slave node can be an inexpensive oscillating circuit (a. k. a. RC circuits) instead of crystals or ceramic oscillators that are used in systems with greater sensitivity to time differences.

This means that control module costs for the LIN standard can be kept down.

A synchronisation procedure is used in each message on LIN in order to make communications, which are still time-dependent, possible. A number of bits at the start of each message are used so that the clock circuit in each slave control module can adjust to the correct frequency so that the subsequent data in the message can be received error-free.

If the LIN bus is inactive for a specific period of time, the slave nodes switch to sleep mode to reduce power consumption.

The transfer rate on LIN can lie between 5 and 20 kbit/s, but Volvo uses 9.6 kbit/s. This can be compared to the transfer rate on the CAN network which is 125-500 kbit/s.

1 kbit/s = 1000 bits per second.

The reason why Volvo has selected a transfer rate of 9.6 kbit/s is the balance between performance and transfer quality. A higher transfer rate can be used in some applications.

On a LIN bus there is always one control module that is the main control module (a. k. a. master node). All other control modules on the same LIN bus are slave nodes.

The master node contains a list describing which slave nodes are connected on the LIN bus in question. The list in the master node also describes which messages can be sent on the LIN bus and in which order.

Messages are sent in order according to the list in the master node with a specific time delay between messages, so that any responses from the slave nodes can be received by the master node.

What the slave nodes shall do and/or which data is to be sent as a response when the slave node receives a message is in turn described in a list that is programmed into each slave node. If a slave node has not managed to respond before it is time for the next message to be sent from the master node, the master node will start to send nevertheless and the slave node will be interrupted during its transmission.

The maximum length of a bus wire is set to 35 m (114.83 ft). The high level on LIN means battery voltage, i. e. approx 9-18 V, yet all circuits connected to the bus must withstand up to approximately 25 V.

The LIN bus is terminated to the battery voltage with a pull-up resistance on all nodes, the master mode with 1 kohms and the slave nodes with 20-47 kohms, usually 30 kohms.

This means that in sleep mode the voltage on the LIN bus is approximately 13 V and the dominant level on the bus (that is to say when a "1" is transmitted and a node takes down the bus to a low level during the transmission) is approximately 1 V.

HINT: The voltage on the communication wire is dependent on the supply voltage. The guideline is that the average value during communication is approximately 2/3 of the supply voltage. With a normal supply voltage and normal communication, the average voltage on the LIN bus lies at approximately 7-8 V.

The residue voltage level depends on the internal protection diodes in the control module.

The slave nodes also have a diode in series with the pull-up resistance to prevent the connected components from loading the bus by leading current the back-way if they do not have a power supply.

WIRING

The communication wire used on LIN is a single, unscreened conductor, which includes the most common cable harnesses in the vehicle. On account of the wire being unscreened, some restrictions due to EMC reasons can apply to wire routing.

LIN MESSAGE

Complete message

Fig. 72: Identifying LIN Message Format
Courtesy of VOLVO CARS CORPORATION

A = Frame

B = Header

C = Message

A message on LIN is called a frame and consist of the following parts:

1. **Synchronisation interrupt.** Used to wake slave nodes that are in sleep mode.
2. **Synchronisation field.** The synchronisation field helps slave nodes to synchronise with their master node's clock frequency, in order for messages sent to be received correctly.
3. **Identification field.** Contains information about the contents of the message. All nodes can read and respond to a message, yet only one node has the right to send a response to the message. Which node has the right to answer the message is evident from the identifier.
4. **Data information.** The data sent can be two to eight bytes long. The data information is sent with the least significant bit first.
5. **Checksum.** The checksum is a way for slave notes to check whether the received message has been transferred correctly, or if any disturbance can have occurred during the transmission which has corrupted the data. If an error has occurred in a message during transmission from the master node to the slave node, i. e. the checksum calculated by the slave node does not correspond, the slave node will erase the message and await the next message sent from the master node.

The slave nodes do not send an acknowledgement to a message that has been received correctly. The master node re-reads the message sent out on the LIN bus and compares the re-read message with the message that was sent.

If the sent and detected messages are the same, the master mode presupposes that the message has been received correctly by the slave nodes.

Example from an oscilloscope

Fig. 73: Identifying Example From An Oscilloscope
Courtesy of VOLVO CARS CORPORATION

If you have access to an oscilloscope and measure on the LIN bus, a start-up procedure with subsequent communication can appear as illustrated in the figure above.

The lower curve is a magnified section of the upper curve.

In the upper curve you first, see the LIN bus in sleep mode with the subsequent message. This is followed by several messages.

The numbers in the different fields correspond to the parts of the message described in the list above.

In the figure you can, see that the sleep voltage on the LIN bus is approximately 13 V and that the voltage drops to approximately 1 V during communication.

NOTE: **The figure above is only one example of how messages on the LIN network can appear.**

NETWORK

GENERAL

Increasing demands on functionality have made the electrical system in vehicles increasingly complex. By using a network with serial communications between the different control modules several functions can be controlled and monitored using fewer cables.

Example of networks using serial communications are CAN and LIN.

LIN is an acronym for and has been jointly developed as a common standard by a number of different automotive manufacturers.

The concept involves the exchange of information, via serial communications with a single wire, between control modules where the same performance as provided by a CAN network is not needed.

LIN is usually used as a communications line between control modules on the CAN network and minor nodes, such as regulators and advanced sensors.

The number of control modules that communicate via LIN is dependent on the vehicle model and the level of equipment.

The difference between CAN and LIN is that the CAN network is routed throughout the entire vehicle. Whereas LIN is usually used in smaller separate networks where the transfer speed and performance is not so highly prioritised.

ADVANTAGES OF A NETWORK

Instead of using a single wire for each function, serial communications over a network make it possible for hundreds of signals and functions to be activated, controlled or read via the same wire.

Using a network it is even easier to adapt the system to customers and markets.

In relation to the number of functions and connected components the length of the wiring is short and the electrical system is more service friendly when based on a network instead of direct connection.

NETWORK STRUCTURE

GENERAL

Fig. 74: Identifying Local Interconnect Network (LIN) Structure
Courtesy of VOLVO CARS CORPORATION

A = Master node

B = Slave node

The network is made up of a number of control modules connected to each other via a communications wire. The control modules are voltage fed and ground individually and exchange information in an optional direction via the communication wiring.

In event of a failure on the communication wiring, the control modules will not be able to communicate with the other control modules located after the failure. However, the control modules located before the failure can still communicate.

On a LIN bus there is always one control module that is the main control module (a. k. a. master node). All other control modules on the same LIN bus are slave nodes.

TERMINATING RESISTOR

Fig. 75: Identifying Terminating Resistor
Courtesy of VOLVO CARS CORPORATION

A = Master node

B = Slave node

C = Transmitter/receiver

LIN is terminated to the battery voltage on each node via a pull-up resistance

The master node is terminated with 1 kohms and the slave nodes with 30 kohms.

The termination resistance forms a parallel circuit and the resistance to the battery voltage depends on the number of connected nodes. The resistance to ground should be infinite or at least extremely large if no communications are in progress.

MD MODULE (MP1) AND CD MODULE (MP2) (2003-2006)

DESIGN

CONTROL MODULE

There are two different media players:

- the MD module (MP1) plays MiniDiscs
- the CD module (MP2), which plays compact discs, can be a single disc player or a CD changer for six CDs.

The magazine for the CD changer is integrated in the control module. The MD Module (MP1) or CD Module (MP2) can be post-installed. A CD player and a CD changer cannot be installed at the same time.

The control modules are in the center console and are integrated in the infotainment control module (ICM).

The display on the infotainment control module (ICM) shows the current status of the selected media player. The media players are operated via the buttons on the infotainment control module (ICM).

All input and output signals from the control modules are transmitted on the MOST network.

DIAGNOSTIC FUNCTIONS

GENERAL

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault.

Should a fault disappear for any reason after being permanently stored in the control module as a diagnostic trouble code (DTC), the information remains stored in the control module.

If a fault is no longer permanent, the diagnostic trouble code (DTC) remains as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

NOTE: Certain functions are unavailable until the diagnostic trouble codes (DTCs) have been erased.

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N.

READING OFF EXTENDED FAULT-TRACING INFORMATION

This function can be used to read parameters, status identifiers and counters stored at the same time as a diagnostic trouble code (DTC). These are called frozen values.

For further information about the MD Module (MP1), see **DESCRIPTION OF VEHICLE COMMUNICATION INFORMATION** .

For further information about the CD Module (MP2), see **DESCRIPTION OF VEHICLE COMMUNICATION INFORMATION** .

READING OFF THE PARAMETERS

Using this function, the status or value of parameters can be read off. The status/value can be presented digitally. For further information about the different parameters, for the MD Module (MP1) see **DESCRIPTION OF PARAMETERS** and for the CD Module (MP2) see **DESCRIPTION OF PARAMETERS** .

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the MD module (MP1) and CD module (MP2). When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

The control module is integrated in the infotainment control module (ICM).

After replacing the control module, the unique serial numbers of the control module are checked by the infotainment control module (ICM). The installed control module will not work if the serial number is incorrect.

Try turning the ignition off and on if there are problems after the software is downloaded and the control module is not working.

The MOST network is used for a total software reload.

FUNCTION

PLAYING DISCS

Fig. 76: Identifying Media Players Function
Courtesy of VOLVO CARS CORPORATION

The function of the media players, MD player (MP1) (16/107) and CD player (MP2) (16/106), is to play back minidiscs and compact discs.

The media players receive input signals from the infotainment control module (ICM) (16/1) via the MOST network. The signals indicate when the user has pressed the Play, Stop or Eject buttons for example.

The MD and CD control modules have next/previous track, fast search forwards and reverse and random play (RND) functions. The CD changer also has a function for selecting the desired disc.

When playing back discs, the MD player (MP1) (16/107) or CD player (MP2) (16/106) transmits a signal on the MOST network to the audio module (AUD) (16/105) which then transmits signals to the loudspeakers and the headset outputs. Text stored on the discs is also transmitted via the MOST network to the display on the infotainment control module (ICM).

SYSTEM OVERVIEW

MD MODULE (MP1) AND CD MODULE (MP2)

Fig. 77: Identifying MD Module (MP1) and CD Module (MP2)
Courtesy of VOLVO CARS CORPORATION

The media players play back MiniDiscs and compact discs. There are two different media players:

- the MD module (MP1) plays MiniDiscs
- the CD module (MP2), which plays compact discs, can be a single disc player or a CD changer for 6 CDs.

The control modules are in the center console.

The media player uses optical serial communication to communicate with other components on the MOST network. This means that all communication with the media player is via the infotainment control module (ICM). The media players are connected to the audio module (AUD) for access to the loudspeakers.

Any diagnostic trouble codes (DTCs) are stored in the control module memory. This information can be read off using VIDA via the data link connector (DLC) in the car.

SIGNALS

The following table summarizes the input signals to and output signals from the media players. These signals type are only transmitted via MOST communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected:	**Directly connected:** (Power supply unless otherwise stated)

Via MOST communication: • Infotainment Control Module (ICM) (16/1).	**Via MOST communication:** • Audio module (AUD) (16/105) • Infotainment Control Module (ICM) (16/1).

Fig. 78: Identifying Volvo's Component Designation
Courtesy of VOLVO CARS CORPORATION

MOST NETWORK (2003-2006)

CONSTRUCTION OF THE NETWORK

GENERAL

Fig. 79: Control Modules On The MOST Network
Courtesy of VOLVO CARS CORPORATION

The MOST network is a fiber optic network in which all the control modules are connected in a ring. All messages within the MOST network go in the same direction from the infotainment control module (ICM) to the antenna module (ATM).

In a fiber optic network, light pulses are transmitted instead of electrical signals. The light pulses are interpreted in the same way as the electrical signals on the CAN network. The MOST network uses the master-slave concept. This means that the infotainment control module (ICM) has overall control of communication on the MOST network.

The fiber optic cable is made of plastic. Communication is using red light on a wavelength of 650 nm.

THE OPTICAL CONNECTOR

Fig. 80: Identifying Optical Connector
Courtesy of VOLVO CARS CORPORATION

Terminal	Signal type	Other
1 / B1	Optical input signal	Input signal for MOST communication
2 / B2	Optical output signal	Output signal for MOST communication

Each control module in the MOST network has an optical connector which consists of two diodes, a sender diode and a receiver diode. These transmit and receive light pulses. The actual communication between two control modules is as follows. A sender diode transmits the message as a light pulse. This is transmitted from the control module via the MOST network to a photo-optical receiver diode in the receiving control module.

The two optical terminals in the connector are numbered in the same way on all control modules in the MOST network. The size of the plastic housing for the two optical terminals varies. A connector with integrated power supply is integrated with the optical terminals and one connector with only the optical terminals.

MOST COMMUNICATION

All messages are transmitted as light pulses in the same direction on the MOST network. This means that if other control modules are connected between the two control modules which are communicating, the light pulses pass through these with no effect on the information. The control modules which are passed through amplify the light pulse so that it does not become too weak.

A control module with an internal fault can be set to bypass mode. In this mode, the light pulses are sent straight through the control module without the control module amplifying the light pulse. This means that the distance before the light pulse is amplified is longer and therefore the luminance is weaker. If the luminance is too weak, it cannot be received by the receiving control module.

The infotainment control module (ICM) is the gateway between the MOST and CAN networks for communication to and from control modules connected on the CAN network.

The infotainment control module (ICM) monitors the communication on the MOST network. This involves distributing sound channels on the MOST network, so that sound data can be distributed from, for example, the CD module (MP2) to the audio module (AUD). The majority of activations on the MOST network are initiated by the infotainment control module (ICM). The infotainment control module (ICM) also manages diagnostic trouble codes (DTCs) on the MOST network.

If a control module in the MOST network stops working and is unable to transmit light pulses onwards, or if there is an open-circuit in the fiber optic cable, the entire MOST network will stop working. This means that all the control modules on the MOST network will stop working. For more information about remedying this, see fault management on the MOST network.

The infotainment control module (ICM) must always be connected on the MOST network for communication on the MOST network to work.

The MOST network connections increase and the signal routing may change when control modules are added because adapter wiring is used to connect the new control module.

LOCATION OF CONTROL MODULES ON THE MOST NETWORK

Fig. 81: Control Modules On The MOST Network
Courtesy of VOLVO CARS CORPORATION

The control modules on the MOST network should be positioned in a particular order. If this order is not followed, the fault-tracing of the MOST network will deteriorate.

When further control modules are added to the MOST network, these should be placed in the correct order on the network to make it easier to fault-trace the control modules. If the control modules are connected in another order, this does not effect the function of the MOST network, but fault-tracing will be compromised. The

control modules should be placed in the following order:

1. Infotainment Control Module (ICM) (16/1)
2. Multimedia module (MMM) (16/108)
3. CD module (MP2) (16/106)
4. Phone module (PHM) (16/60)
5. MD module (MP1) (16/107)
6. Audio module (AUD) (16/105)
7. Subwoofer module (SUB) (16/79)
8. Antenna module (ATM) (16/110).

If the MD module (MP1) is installed as an aftermarket accessory in a car with a phone module (PHM) and CD module (MP2), the MD module (MP1) will change positions with the phone module (PHM).

If the configuration of the MOST network in the car is minimal, the following control modules are connected:

- infotainment control module (ICM)
- the audio module (AUD)
- the antenna module (ATM).

CONTROL MODULES IN THE MOST NETWORK

MOST NETWORK

Fig. 82: Identifying MOST Network Control Modules (Up To Eight)
Courtesy of VOLVO CARS CORPORATION

The MOST network can consist of up to eight control modules.

The infotainment control module (ICM) monitors the MOST network and manages communication. The infotainment control module (ICM) is monitored by the central electronic module (CEM) on the controller area network (CAN). In addition to the infotainment control module (ICM), there are two control modules which are standard on the MOST network. These are:

- the audio module (AUD)
- the antenna module (ATM).

The table below lists all the control modules which may be included in the MOST network.

Explanation

CAN = Controller Area Network, electrical network for communication

LS CAN = low speed side of the CAN

MOST = Media Oriented Systems Transport, fiber optic network for communication

Master control module = Control module which monitors the MOST network

Slave control module = Control module which supplies the MOST network functions

Option = accessory installed at the factory during the purchase of a new car

Accessory = after market installation

(x) = position number in the illustration

Control module	Function	Communication	Other
Infotainment Control Module (ICM) (1)	Monitors the MOST network.	The master control module is connected to both the LS CAN and the MOST network.	Included in the standard set-up of the MOST network. Must be connected to the MOST network to function.
Multimedia Module (MMM) (2)	Displays traffic information on the directly connected display screen.	Slave module on the MOST network.	Option, accessory
Phone module (PHM) (4)	Controls carphone functions.	Connected to the LS CAN and is a slave module on the MOST network.	Option, accessory
MD module (MP1) (3)	Plays minidisks.	Slave module on the MOST network.	Option, accessory
CD module (MP2) (5)	Plays CDs. Can consist of a CD player or CD changer	Slave module on the MOST network.	Option, accessory
Antenna module (ATM) (8)	Consists of an AM/FM antenna. May also have a GPS unit and TMC unit as an option.	Slave module on the MOST network.	Included in the standard set-up of the MOST network.
Audio module (AUD) (6)	Amplifier connected to all loudspeakers except the subwoofer module (SUB). The microphone and headset panel are also directly connected to this control module.	Slave module on the MOST network.	Included in the standard set-up of the MOST network.
Subwoofer module (SUB) (7)	Amplifier and bass speakers integrated in the same unit.	Slave module on the MOST network	Option, accessory. The audio module (AUD) must be connected to the MOST network for the subwoofer module (SUB) to function.

FAULT MANAGEMENT ON THE MOST NETWORK

GENERAL

The MOST network is monitored by the infotainment control module (ICM). If it detects a fault in the MOST network, a diagnostic trouble code (DTC) is stored in the infotainment control module (ICM). There are different types of diagnostic trouble codes (DTCs) depending on the type of fault. A general rule is that if the light pulse in the MOST network disappears, the entire network stop working.

Fault types which are processed are:

- no communication from a control module
- faulty communication on the MOST network.

NO COMMUNICATION FROM A CONTROL MODULE

The infotainment control module (ICM) knows which control modules are connected to the MOST network. If any control module on the MOST network stops communicating, a diagnostic trouble code (DTC) is stored in the infotainment control module (ICM). There is a diagnostic trouble code (DTC) for each control module on the MOST network for this fault. The diagnostic trouble codes (DTCs) are ICM-1A51 to ICM-1A57.

Diagnostic trouble codes (DTCs) for missing communication are also stored for additional GPS and TMC units which are connected to the antenna module (ATM). The diagnostic trouble codes (DTCs) are ICM-1A58 and ICM-1A59.

Missing communication may be due to an internal fault in the control module or because the function is incorrectly implemented in the control module.

FAULTY COMMUNICATION

Diagnostic trouble code (DTC) ICM-DC00 is stored in the event of internal faults in the infotainment control module (ICM) preventing the transmitting and receiving diodes from sending sound pulses on the MOST network.

For faults when messages cannot be sent on the MOST network, diagnostic trouble code (DTC) ICM-DC02 is stored Causes of this fault may be that:

- a control module, except the infotainment control module (ICM), has a defective optical connector
- a control module has an internal fault, which means that the optical connection stops working
- a control module on the MOST network is not powered. If there is no power supply, the optical connecter stops transmitting light
- the optical cable is damaged or there is a break in it. This fault may occur if the bend radius of the cable is too small or the cable has been folded
- there is dirt or oil on the optical connectors which impedes the light
- the connection to a control module has come loose
- the fiber optic terminals in the connector are cross-connected
- there is a loose connection because the fiber optical wiring is incorrectly installed or the fiber optic terminal pin has been pressed back in the connector
- a bridging connector has come loose or is damaged.

Ring break diagnostics are used to remedy diagnostic trouble code (DTC) ICM-DC02. If a break is discovered in the MOST network after running a ring break diagnostic, diagnostic trouble code (DTC) ICM-DC01 will be stored in the infotainment control module (ICM). If this is the case, the position of the open-circuit and control module location, can be read off from the infotainment control module (ICM).

RING BREAK DIAGNOSTICS

General

This function is important when fault-tracing the MOST network. Ring break diagnostics are used when there is an open-circuit in the MOST network and diagnostic trouble code (DTC) ICM-DC02 has been stored in the infotainment control module (ICM).

During fault-tracing, all control modules transmit a message to the infotainment control module (ICM) in reverse order in relation to the position on the network. This means that the antenna module (ATM) is first, not last. The control module which is not working will not transmit an answer to the infotainment control module (ICM). This also means that the control modules connected after the defective control module will be unable to transmit a message to the infotainment control module (ICM).

The same applies in the event of an open-circuit in the fiber optic cable in the MOST network. None of the control modules before the open-circuit will be able to send their message to the infotainment control module (ICM). The infotainment control module (ICM) is then able to calculate the position of the open-circuit from the incoming messages.

HINT: It is important to know which control modules are connected and in what order to identify the control module which sends each message.

Fig. 83: Identifying Open-Circuit Between The Phone Module (PHM) And The MD Module (MP1)
Courtesy of VOLVO CARS CORPORATION

Example 1

A MOST network contains all eight control modules.

There is an open-circuit in the wiring between the phone module (PHM) and the MD module (MP1). See the illustration.

During the ring break diagnostic, the infotainment control module (ICM) receives responses in reverse order to the order of the control modules. Those that are located before the MD module (MP1) cannot respond to the infotainment control module (ICM).

The infotainment control module (ICM) receives responses up to position four and presents the value 4.

If there was no open-circuit, the infotainment control module (ICM) would have responded "OK".

Example 2

A MOST network to which the subwoofer module (SUB) is not connected, however the other seven control modules are connected.

There is an open-circuit in the wiring between the phone module (PHM) and the CD module (MP2).

During the ring break diagnostic, the response value from all the control modules before the subwoofer module (SUB) will be one less than example 1 when all control modules are connected.

The infotainment control module (ICM) receives responses up to position three and presents the value 3.

If there was no open-circuit, the infotainment control module (ICM) would have responded "OK".

MOST NETWORK

GENERAL

MOST (Media Oriented Systems Transport) is a standardized network communication system for multimedia applications. The MOST protocol is optimized for fiber optic communication. This means that signals are sent as light pulses.

MOST DATA

The MOST protocol determines how light pulses, or the absence of light pulses should be interpreted. Each pulse or absent pulse is called a "bit". The number of "bits" transmitted on the MOST network is 24.8 million per second (24.8 Mbps). A bit can be:

- binary 0, i. e. no light pulse
- binary 1, i. e. light pulse.

The light pulses are transmitted in data frames. A data frame consists of different types of data. The size of a data frame is 64 bytes, which is 64 x 8 = 512 bits.

The data frame has a frequency of 48 kHz. This means that 48000 data frames are sent per second on the MOST network.

The data types which are included in a data frame sent on the MOST network are:

- control data
- synchronous data
- asynchronous data
- administrative data.

Control data

Control data is used to check and to allocate the functions to the control modules and the functions in the MOST network.

The control data message is transmitted from, for example, the infotainment control module (ICM) to another specific control module. The control data message automatically checks if the receiver has received the signal and that the entire message has been correctly transmitted between the transmitting and receiving control modules.

The size of the control data is 2 bytes per data frame. A block, which consists of 16 data frames, is required for a control message to be sent. This means that the total size of the control message is 32 bytes. A control message is the minimum size of a message to activate or deactivate functions in control modules on the MOST network.

Examples of MOST messages are track changes or stop commands on the CD player.

Up to 1000 control data messages can be sent per second.

Synchronous data

Synchronous data is used to transmit data which requires considerable quantities of data in real time, for example to play back sound from the CD module (MP2).

The length of the synchronous data message which can be sent may be up to 60 bytes per data frame, although never less than 24 bytes. This gives a transfer rate of up to 23 Mbits per second for data transmitted as synchronous data.

Synchronous data shares the data frame with asynchronous data. The infotainment control module (ICM) controls which control modules transmit synchronous data and which are receivers.

Asynchronous data

Asynchronous data is used to send large quantities of data, such as TCP/IP and digital images, but not in real time.

The length of the message can be up to 36 bytes (synchronous data minimum 24 bytes + asynchronous data 36 bytes = 60 bytes). This gives a maximum transfer rate of 14 Mbits per second. When the message has been sent, a check is run to ensure that is has been correctly received.

Asynchronous data shares the data frame with synchronous data. The infotainment control module (ICM) controls which control modules transmit asynchronous data and which are receivers.

Administrative data

Administrative data consists of two parts. The first part is at the start of the data frame. This describes how much of the data is synchronous and how much is asynchronous.

The second part is at the end of the data frame. This part checks that the control modules on the MOST network are working correctly.

The size of administrative data is 2 bytes.

MOST DATA FRAME

Fig. 84: Identifying MOST Data Frame
Courtesy of VOLVO CARS CORPORATION

A data frame consists of different parts. This consists of check data, asynchronous, synchronous and administrative data. A data frame on the MOST network is 64 bytes. The data frame consists of the following:

1. synchronization of the clock on the MOST network, i. e. the frequency at which data is transmitted so that the data is sent at the correct intervals
2. administrative data, indicates the size of the asynchronous and synchronous data
3. synchronous data
4. asynchronous data
5. control data
6. administrative data.

16 data frames are required to form a block. One block is the minimum size of a MOST message.

MOST PROTOCOL

All activations on the MOST network are control messages or MOST messages. The majority of the MOST messages are initiated by the infotainment control module (ICM). The infotainment control module (ICM) informs certain control modules if a function in the control module should be activated. The infotainment control module (ICM) then creates space on the MOST network for the activations in the control module to transmit data, either synchronous or asynchronous. The structure of a message is as follows:

- DeviceID. FBlockID. InstID. FktID. OPType.

This means:

- DeviceID - The ID number of one of more control modules in the network
- FBlockID - The ID number of a function unit, for example the CD function in the CD module (MP2)
- InstID - The ID number to differentiate between identical function units, for example two CD modules in the MOST network
- FctID - The ID number of the function to be activated, for example play or stop
- OPType - Specifies how the function is to be used, because a function can be used in different ways.

The message may appear as follows:

- MP2. CD.01. Track, Length. Set(10).

This means: play song number 10 on the CD player in the CD module (MP2).

The infotainment control module (ICM) knows which control modules are in the MOST network. It can then assign specific ID numbers to all control modules and the included functions. If control modules are removed or added, the ID numbers for the control modules are re-assigned.

CALCULATING THE TRANSFER RATE

The number of "ones" and "zeros" transmitted per second determines the transfer rate.

The number of data frames multiplied by the clock frequency of a frame gives the transfer rate.

Example

The maximum transfer rate of asynchronous data:

Bit = a binary 1 or 0

Replace = 8 bit

Maximum asynchronous data = 36 byte

This gives: 36 x 8 = 288 bit

The clock frequency for a data frame = 48 kHz

The maximum number of bits of asynchronous data x clock frequency for a frame: 288 x 48000 = 14 Mbit/s.

SOFTWARE DOWNLOADS ON THE MOST NETWORK

The concept for downloading software is the same as for the CAN network. The CAN uses a PBL (primary boot

loader) which is permanently installed in the control module, and a secondary program loading file (SBL - secondary boot loader) which is downloaded into a RAM while the control module is being programmed.

When downloading software for the MOST control modules, a third type of download module is used, GBL (Gateway boot loader). For downloads to the MOST control modules to work, the GBL must be loaded into the infotainment control module (ICM). The GBL cannot be used to program the infotainment control module (ICM). SBL is used to program the infotainment control module (ICM), in the same way as all the other CAN control modules

GBL downloading

A PROG command is transmitted on the CAN network to all control modules including the infotainment control module (ICM). This command sets all the control modules to reset mode. Before the infotainment control module (ICM) switches to reset mode, it switches of the light to all MOST control modules.

The PROG command on the CAN network sets all CAN control modules to programming mode. The MOST network is inactive during this phase.

The GBL is then downloaded to a RAM memory in the infotainment control module (ICM). The GBL is then activated and the infotainment control module (ICM) transmits light pulses on the MOST network. The GBL now functions as a connection between the CAN and MOST networks. The GBL sets the MOST control modules to programming mode. All the control modules on the MOST and CAN networks can then be addressed in the same way to download software.

In the event of a total software reload for the control modules on the MOST network, select the MOST network option. Select CAN network for control modules on the controller area network (CAN).

SECURITY ON MOST

This function is used to ensure that all control modules on the MOST network can be used. The MOST network starts in ignition positions I, II or III. The infotainment control module (ICM) checks that all the control modules on the MOST network have a valid serial number. If the infotainment control module (ICM) detects that one or more control modules does not have a valid serial number, those particular control modules will be set to disabled mode. This means that the control module functions cannot be used in the MOST network. The light pulses can only pass through the control module.

THE NETWORK

GENERAL

The increasing requirements of extended functionality in cars has underpinned the development of systems with better performance and more functions. The MOST network is a result of this development. The MOST network is a fiber optic network which allows a high number of different commands and messages to be sent and received on the same cable and in the same direction. By using a fiber optic network, functionality is extended without increasing the amount of wiring.

The number of commands and messages which can be handled on the network depends on factors such as the network speed and the length of the message or command. The MOST network which is used in Volvo cars has

the capacity to transmit over 300 message types and approximately 1000 messages per second. The transfer rate on the MOST network is approximately 25 Mbps.

ADVANTAGES OF AN OPTICAL NETWORK

- electrical short-circuits are not possible on the MOST network. This reduces the risk of damage to control modules connected to the network
- As an optical network, the MOST network does not have problems with EMC (Electro Magnetic Compatibility)
- the wiring is not sensitive to electrical cross-induction from other wiring
- The transfer speed of the MOST network is much higher than the CAN network
- it is easy to add further functions and to install accessories, known as plug and play units.

The control modules in the network are connected to each other and are constructed so that more functionality can be easily added. All that is required to increase functionality is to:

- connect the sensor to the closest control module
- connect the controlled component to the nearest control module
- download software to change the configuration and programming of the network.

MOST NETWORK (2009-2012)

CONTROL MODULES IN MOST NETWORK

MOST-NETWORK

Fig. 85: Identifying MOST Network Control Modules (Up To Eight)
Courtesy of VOLVO CARS CORPORATION

Model year 2011-

Fig. 86: Identifying MOST Network Control Modules (Up To Seven)
Courtesy of VOLVO CARS CORPORATION

The MOST network can consist of up to seven different control modules.

The infotainment control module (ICM) deals with monitoring and communication on the MOST network. The infotainment control module (ICM) is in turn monitored by the central electronic module (CEM) on the CAN network.

From the Infotainment Control Module (ICM), the Integrated Audio Module (IAM) is included as standard on the MOST network.

The table below lists all the control modules which may be included in the MOST network.

Explanation

CAN = Controller Area Network, electrical network for communication.

LS CAN = CAN low-speed side

MOST = Media Oriented Systems Transport, fiber optic network for communication.

Master control module = Control module which monitors the MOST network.

Slave control module = Control module which supplies the MOST network functions.

Option = Factory installed accessories, during the purchase of a new car.

Accessory = After market installation.

Control module	Function	Communication	Miscellaneous
Infotainment control module (ICM)	Monitors the MOST network.	Master control module, connected to both the LS CAN and the MOST network	Included in the standard set-up of the MOST network. Must be connected to the MOST network to function.
Remote Digital Audio Receiver (RDAR)	Receives and decodes digital radio signals. Has a directly connected antenna.	Slave module on the MOST network.	Option, accessory. Only USA/CDN.
Phone module (PHM)	Controls carphone functions.	Connected to the LS CAN and is a slave module on the MOST network.	Option, accessory. The audio module (AUD) must be connected to the MOST network for the Phone module (PHM) to function.
Audio module (AUD)	Amplifier to which all speakers except the subwoofer module (SUB) are connected.	Slave module on the MOST network.	Option, accessory. Included in sound systems High Performance and Premium Sound.
Multimedia module (MMM)	Displays traffic information on the directly connected display screen. GPS receiver for determining the position of the vehicle.	Slave module on the MOST network.	Option, accessory.
Global positioning system module (GPS)	Calculates the vehicle's position using a GPS signal. Has directly connected GPS antenna.	Slave module on the MOST network.	Option, accessory. The global positioning system module (GPS) is only connected if the vehicle is equipped with telematics but does not have a Multimedia module (MMM).
Integrated Audio	Has its own AM/FM aerial. The performance model has 4 loudspeakers. For the High performance	Slave module on the MOST	Included in the standard set-up of the MOST

Module (IAM)	and Premium Sound models, the audio module (AUD) is required.	network.	network.
Accessory USB unit (AUU)	Enables listening to the customer's portable media players in the vehicle's speaker system via USB-port.	Slave module on the MOST network.	Option, accessory.
Bluetooth phone module (BPM)	Functions as a wireless link between the vehicle's infotainment system and driver's or passenger's mobile telephone equipped with Bluetooth technology.	Slave module on the MOST network.	Option, accessory.

FAULT MANAGEMENT ON MOST NETWORK

GENERAL

The MOST network is monitored by the infotainment control module (ICM). If it detects a fault in the MOST network, a diagnostic trouble code (DTC) is stored in the infotainment control module (ICM). There are different types of diagnostic trouble codes (DTCs) depending on the type of fault. A general rule is that if the light pulse in the MOST network disappears, the entire network stops working.

Fault types which are processed are:

- no communication from a control module
- faulty communication on the MOST network.

NO COMMUNICATION FROM A CONTROL MODULE

The infotainment control module (ICM) knows which control modules are connected to the MOST network. If any control module on the MOST network ceases to communicate, a diagnostic trouble code (DTC) is stored in the infotainment control module (ICM). There is a diagnostic trouble code (DTC) for every control module on the MOST network for this fault.

Missing communication may be due to an internal fault in the control module or because the function is incorrectly implemented in the control module.

FAULTY COMMUNICATION

Diagnostic trouble code (DTC) ICM-DC00 is stored in the event of an internal fault in the infotainment control module (ICM) preventing the transmitting and receiving diodes from sending sound pulses on the MOST network.

For faults when messages cannot be sent on the MOST network, diagnostic trouble code (DTC) ICM-DC02 is stored.

Causes of this fault may be that:

- a control module, except the infotainment control module (ICM), has a defective optical connector
- a control module has an internal fault which means that the optical connection stops working
- a control module on the MOST network is not powered. If there is no power supply, the optical connecter stops transmitting light
- the optical cable is damaged or there is an open-circuit. This fault can occur if the bend radius of the cable is too small or if the cable is kinked or trapped
- there is dirt or oil on the optical connectors which impedes the light
- the connection to a control module has come loose
- the fiber optic terminals in the connector are cross-connected
- there is a loose connection because the fiber optical wiring is incorrectly installed or the fiber optic terminal pin has been pressed back in the connector
- a bridging connector has come loose or is damaged.

Ring break diagnostics are used to remedy diagnostic trouble code (DTC) ICM-DC02. If a break is discovered in the MOST network after running a ring break diagnostic, diagnostic trouble code (DTC) ICM-DC01 will be stored in the infotainment control module (ICM). If this is the case, the position of the open-circuit and control module location, can be read off from the infotainment control module (ICM).

RING BREAK DIAGNOSTICS

General

This function is important when fault-tracing the MOST network. Ring break diagnostics are used when there is an open-circuit in the MOST network and diagnostic trouble code (DTC) ICM-DC02 has been stored in the infotainment control module (ICM).

During a ring break diagnostic, all control modules transmit a message to the infotainment control module (ICM) in reverse order to their position on the MOST network. This means that the Integrated Audio Module (IAM) transmits first, not last.

The control module which is not working will not transmit a response to the infotainment control module (ICM). This also means that the control modules which are connected before the defective control module will be unable to transmit a message to the infotainment control module (ICM).

The same applies in the event of an open-circuit in the fiber optic cable in the MOST network. None of the control modules before the open-circuit will be able to send their message to the infotainment control module (ICM). The infotainment control module (ICM) is then able to calculate the position of the open-circuit from the incoming messages.

HINT: It is important to know which control modules are connected and in what order to identify the control module which sends each message.

Example

Fig. 87: Identifying An Open Circuit Between The Audio Module (AUD) And The Accessory USB Unit (AUU)
Courtesy of VOLVO CARS CORPORATION

A MOST network with all control modules.

An open circuit occurs on the cable between the Audio module (AUD) and the Accessory USB unit (AUU), see figure.

The infotainment control module (ICM) receives responses up to and including the Accessory USB unit (AUU) and presents the value 3.

If there was no open-circuit, the infotainment control module (ICM) would have responded "OK.

MOST-NETWORK

GENERAL

MOST (Media Oriented Systems Transport) is a standardized network communication system for multimedia applications. The MOST protocol is optimized for fiber optic communication. This means that signals are sent as light pulses.

MOST DATA

The MOST protocol determines how light pulses or their absence should be interpreted. Each pulse or absent pulse is called a "bit". The number of "bits" transmitted on the MOST network is 24.8 million per second (24.8 Mbit/s).

A bit can be:

- binary 0, i. e. no light pulse
- binary 1, i. e. light pulse.

The light pulses are transmitted in data frames. A data frame consists of different types of data. The size of a data frame is 64 bytes, which is 64 x 8 = 512 bits.

The data frame has a frequency of 48 kHz. This means that 48000 data frames are sent per second on the MOST network.

The data types which are included in a data frame sent on the MOST network are:

- control data
- synchronous data
- asynchronous data
- administrative data.

Control data

Control data is used to check and to allocate the functions to the control modules and the functions in the MOST network.

The control data message is transmitted from, for example, the infotainment control module (ICM) to another specific control module.

The control data message automatically checks if the receiver has received the signal and that the entire message has been correctly transmitted between the transmitting and receiving control modules.

The size of the control data is 2 bytes per data frame. A block, which consists of 16 data frames, is required for a control message to be sent. This means that the total size of the control message is 32 bytes. A control message is the minimum size of a message to activate or deactivate functions on the MOST network.

Examples of MOST messages are track changes or stop commands on the CD player.

Up to 1000 control data messages can be sent per second.

Synchronous data

Synchronous data is used to transmit data which requires considerable quantities of data in real time, for example to play back sound to the Audio Module (AUD).

The length of the synchronous data message which can be sent may be up to 60 bytes per data frame, although never less than 24 bytes. This gives a transfer rate of up to 23 Mbits per second for data transmitted as synchronous data.

Synchronous data shares the data frame with asynchronous data. The infotainment control module (ICM) controls which control modules transmit synchronous data and which are receivers.

Asynchronous data

Asynchronous data is used to send large quantities of data, such as TCP/IP and digital images, but not in real

time.

The length of the message can be up to 36 bytes (synchronous data minimum 24 bytes + asynchronous data 36 bytes = 60 bytes). This gives a maximum transfer rate of 14 Mbits per second. When the message has been sent, a check is run to ensure that is has been correctly received.

Asynchronous data shares the data frame with synchronous data. The infotainment control module (ICM) controls which control modules transmit asynchronous data and which are receivers.

Administrative data

Administrative data consists of two parts.

The first part is at the start of the data frame. This describes how much of the transmitted data is synchronous and how much is asynchronous.

The second part is at the end of the data frame. This part checks that the control modules on the MOST network are working correctly.

The size of administrative data is 2 bytes.

MOST DATA FRAME

Fig. 88: Identifying MOST Data Frame

Courtesy of VOLVO CARS CORPORATION

A data frame consists of different parts. This contains for example:

- control data
- asynchronous data
- synchronous data
- administrative data.

A data frame on the MOST network is 64 bytes. The data frame consists of the following:

1. synchronization of the clock on the MOST network, i. e. the frequency at which data is transmitted so that the data is sent at the correct intervals
2. administrative data, indicates the size of the asynchronous and synchronous data
3. synchronous data
4. asynchronous data
5. control data
6. administrative data.

16 data frames are required to form a block. One block is the minimum size of a MOST message.

MOST PROTOCOL

All activations on the MOST network are control messages or MOST messages. The majority of the MOST messages are initiated by the infotainment control module (ICM). The infotainment control module (ICM) informs certain control modules if a function in the control module must be activated. The infotainment control module (ICM) then allocates space to transmit data on the MOST network for those activations which have been initiated in the control modules. This is either synchronous or asynchronous data. The structure of a message is as follows:

- DeviceID. FBlockID. InstID. FktID. OPType

This means:

- DeviceID - ID-number of one or several control modules in the network
- FBlockID - ID-number of a function unit, for example, the CD-function in the integrated audio module (IAM)
- InstID - ID-number to separate identical function units, e. g., two CD-control modules in the MOST-net
- FktID - ID-number for the function that is to be performed, e. g., play or stop
- OPType - Specifies how function is to be used, since a function can be used in different ways.

The message may appear as follows:

- IAM. CD.01. Track, Length. Set(10)

This means: play song number 10 on the CD player in the Integrated Audio Module (IAM).

The infotainment control module (ICM) knows which control modules are in the MOST network. It can then assign specific ID numbers to all control modules and the included functions. If control modules are removed or added, the ID numbers for the control modules are re-assigned.

CALCULATING THE TRANSFER RATE

The number of "ones" and "zeros" transmitted per second determines the transfer rate.

The number of data frames multiplied by the clock frequency of a frame gives the transfer rate.

Example

The maximum transfer rate of asynchronous data:

Bit = a binary 1 or 0

Byte = 8 bit

Maximum asynchronous data = 36 byte

This gives: 36 x 8 = 288 bit

The clock frequency for a data frame = 48 kHz

The maximum number of bits of asynchronous data x clock frequency for a frame: 288 x 48000 = 14 Mbit/s.

SOFTWARE DOWNLOADS ON THE MOST NETWORK

The concept for downloading software is the same as for the CAN network. The CAN uses a PBL (primary boot loader) which is permanently installed in the control module, and a secondary program loading file (SBL - secondary boot loader) which is downloaded into a RAM while the control module is being programmed.

When downloading software for the MOST control modules, a third type of download module is used, GBL (Gateway boot loader). For downloads to the MOST control modules to work, the GBL must be loaded into the infotainment control module (ICM). SBL is used to program the infotainment control module (ICM), in the same way for all other CAN control modules.

GBL downloading

A PROG command is transmitted on the CAN network to all control modules including the infotainment control module (ICM). This command sets all the control modules to reset mode. Before the infotainment control module (ICM) switches to reset mode, it switches off the light to all MOST control modules.

The GBL is then downloaded to a RAM memory in the infotainment control module (ICM). The GBL is then activated and the infotainment control module (ICM) transmits light pulses on the MOST network. The GBL now functions as a connection between the CAN and MOST networks. The GBL sets the MOST control

modules to programming mode. All the control modules on the MOST and CAN networks can then be addressed in the same way to download software.

In the event of a total software reload for the control modules on the MOST network, select the MOST network option. Select CAN network for control modules on the controller area network (CAN).

SECURITY ON MOST

This function is used to ensure that all control modules on the MOST network can be used. When the MOST network starts up, ignition position I, II or III, the infotainment control module (ICM) checks that all control modules on the MOST network have approved serial numbers. If the infotainment control module (ICM) detects that one or more control modules do not have approved serial numbers, these modules will be set to disable mode. This means that the control module functions cannot be used in the MOST network. The control module only acts as a conduit for the light pulses.

It takes 30 seconds for the infotainment control module (ICM) to check the control modules. This means that non-approved control modules will be disabled after 30 seconds.

NETWORK DESIGN

GENERAL

Fig. 89: Identifying MOST Network Control Modules (Up To Eight)
Courtesy of VOLVO CARS CORPORATION

Model year 2011-

Fig. 90: Identifying MOST Network Control Modules (Up To Seven)
Courtesy of VOLVO CARS CORPORATION

The MOST network is an optical network in which all control modules included are connected in a ring. All messages in the MOST network travel in one and the same direction from the infotainment control module (ICM) to the integrated audio module (IAM).

In a fiber optic network, light pulses are transmitted instead of electrical signals. The light pulses are interpreted in the same way as the electrical signals on the CAN network.

The MOST network uses the master-slave concept. This means that a master control module, infotainment control module (ICM) has overall control of communication on the MOST network.

The fiber optic cable is made of plastic. Communication is using red light on a wavelength of 650 nm.

THE OPTICAL CONNECTOR

Fig. 91: Identifying Optical Connector
Courtesy of VOLVO CARS CORPORATION

Terminal	Signal type	Miscellaneous
1 / B1	Optical input signal	Input signal for MOST communication
2 / B2	Optical output signal	Output signal for MOST communication

Each control module in the MOST network has an optical connector which consists of two diodes, a sender diode and a receiver diode. These transmit and receive light pulses.

The actual communication between two control modules is as follows. A sender diode transmits the message as a light pulse. This is transmitted from the control module via the MOST network to a photo-optical receiver diode in the receiving control module.

The two optical terminals in the connector are numbered in the same way on all control modules in the MOST network. The size of the plastic housing for the two optical terminals varies. A connector with integrated power supply is integrated with the optical terminals and one connector with only the optical terminals.

MOST COMMUNICATION

All messages are transmitted as light pulses in the same direction on the MOST network. This means that if other control modules are connected between the two control modules which are communicating, the light pulses pass through these with no effect on the information. The control modules which are passed through amplify the light pulse so that it does not become too weak.

A control module with an internal fault can be set to bypass mode. In this mode, the light pulses are sent straight through the control module without the control module amplifying the light pulse. This means that the distance before the light pulse is amplified is longer and therefore the luminance is weaker. If the light pulse is too weak, it cannot be received by the receiving control module.

The infotainment control module (ICM) is the gateway between the MOST and CAN networks for communication to and from control modules connected on the CAN network.

The infotainment control module (ICM) monitors the communication on the MOST network. This involves distributing sound channels on the MOST network, so that sound data can be distributed from, for example, the Remote Digital Audio Receiver (RDAR) to the Integrated Audio Module (IAM). The majority of activations on the MOST network are initiated by the infotainment control module (ICM).

The infotainment control module (ICM) also manages diagnostic trouble codes (DTCs) on the MOST network.

If a control module on the MOST network stops working and is unable to transmit light pulses onwards, or if there is an open-circuit in the fiber optic cable, the entire MOST network will stop working. This means that all the control modules on the MOST network will stop working. For further information about remedying this, see: **FAULT MANAGEMENT ON MOST NETWORK**

The infotainment control module (ICM) must always be connected on the MOST network for communication on the MOST network to work.

The MOST network connections increase and the signal routing may change when control modules are added because adapter wiring is used to connect the new control module.

LOCATION OF CONTROL MODULES ON THE MOST NETWORK

Fig. 92: Identifying MOST Network Control Modules (Up To Eight)
Courtesy of VOLVO CARS CORPORATION

Model year 2011-

Fig. 93: Identifying MOST Network Control Modules (Up To Seven)
Courtesy of VOLVO CARS CORPORATION

NOTE: **The control modules on the MOST network should be positioned in a particular order. If this order is not followed, the fault-tracing of the MOST network will be more difficult.**

When a control module is added to the MOST network, it should be placed in the correct order on the network to make it easier to fault-trace the control modules.

If the control modules are connected in another order, this does not effect the function of the MOST network, but fault-tracing will be more difficult.

The control modules should be placed in the following order:

1. Infotainment control module (ICM)
2. The Remote Digital Audio Receiver (RDAR)/Phone module (PHM)
3. Audio module (AUD)

4. Accessory USB unit (AUU)
5. Multimedia module (MMM)/Global positioning system module (GPS)
6. Integrated Audio Module (IAM)

Model year 2011-

The following order applies to model year 2011 onwards:

1. Infotainment control module (ICM)
2. Remote Digital Audio Receiver (RDAR)
3. Phone module (PHM)
4. Audio module (AUD)
5. Multimedia module (MMM)
6. Integrated Audio Module (IAM)
7. Bluetooth phone module (BPM)

If the minimum configuration of control modules on the MOST network in the car is used, the following control modules are connected:

- infotainment control module (ICM)
- Integrated Audio Module (IAM)

THE NETWORK

GENERAL

The increasing requirements of extended functionality in vehicles has underpinned the development of systems with better performance and more functions. The MOST network is a result of this development.

The MOST network is a fiber optic network which allows a high number of different commands and messages to be sent and received on the same cable and in the same direction.

By using a fiber optic network, functionality is extended without increasing the amount of wiring.

The number of commands and messages which can be handled on the network depends on factors such as the network speed and the length of the message or command. The MOST network which is used in Volvo cars has the capacity to transmit over 300 message types and approximately 1000 messages per second. The transfer rate on the MOST network is approximately 25 Mbit/s.

ADVANTAGES OF AN OPTICAL NETWORK

- electrical short-circuits are not possible on the MOST network. This reduces the risk of damage to control modules connected to the network
- As an optical network, the MOST network does not have problems with EMC (Electro Magnetic Compatibility)

- the wiring is not sensitive to electrical cross-induction from other wiring
- The transfer speed of the MOST network is much higher than the CAN network
- it is easy to add further functions and to install accessories, known as plug and play units.

The control modules in the network are connected to each other and are constructed so that more functionality can be easily added. All that is required to increase functionality is:

- to connect the sensors to the nearest control module
- to connect the controlled component to the nearest control module
- to download software to change the configuration and programming of the network.

MOST NETWORK (2007-2008)

CONTROL MODULES IN MOST NETWORK

MOST-NETWORK

Fig. 94: Control Modules In MOST Network
Courtesy of VOLVO CARS CORPORATION

The MOST network can consist of up to seven different control modules.

The infotainment control module (ICM) deals with monitoring and communication on the MOST network. The infotainment control module (ICM) is in turn monitored by the central electronic module (CEM) on the CAN network.

From the Infotainment Control Module (ICM), the Integrated Audio Module (IAM) is included as standard on the MOST network.

The table below lists all the control modules which may be included in the MOST network.

Explanation

CAN = Controller Area Network, electrical network for communication.

LS CAN = low speed side of the CAN

MOST = Media Oriented Systems Transport, fiber optic network for communication.

Master control module = Control module which monitors the MOST network.

Slave control module = Control module which supplies the MOST network functions.

Option = Factory installed accessories, during the purchase of a new car.

Accessory = After market installation.

Control module	Function	Communication	Miscellaneous
Infotainment control module (ICM)	Monitors the MOST network.	Master control module, connected to both the LS CAN and the MOST network	Included in the standard set-up of the MOST network. Must be connected to the MOST network to function.
Remote Digital Audio Receiver (RDAR)	Receives and decodes digital radio signals. Has a directly connected antenna.	Slave module on the MOST network.	Option, accessory. Only USA/CDN.
Phone module (PHM)	Controls carphone functions.	Connected to the LS CAN and is a slave module on the MOST network.	Option, accessory. The audio module (AUD) must be connected to the MOST network for the Phone module (PHM) to function.
Audio module (AUD)	Amplifier to which all speakers except the subwoofer module (SUB) are connected.	Slave module on the MOST network.	Option, accessory. Included in sound systems High Performance and Premium Sound.

Multimedia module (MMM)	Displays traffic information on the directly connected display screen. GPS receiver for determining the position of the vehicle.	Slave module on the MOST network.	Option, accessory.
Global positioning system module (GPS)	Calculates the vehicle's position using a GPS signal. Has directly connected GPS antenna.	Slave module on the MOST network.	Option, accessory. The global positioning system module (GPS) is only connected if the vehicle is equipped with telematics but does not have a Multimedia module (MMM).
Integrated Audio Module (IAM)	Has its own AM/FM aerial. The performance model has 4 loudspeakers. For the High performance and Premium Sound models, the audio module (AUD) is required.	Slave module on the MOST network.	Included in the standard set-up of the MOST network.
Accessory USB unit (AUU)	Enables listening to the customer's portable media players in the vehicle's speaker system via USB-port.	Slave module on the MOST network.	Option, accessory. Applies from and incl. structure week 200709.
Subwoofer module (SUB)	Amplifier and bass speakers integrated in the same unit.	Slave module on the MOST network.	Option, accessory. The audio module (AUD) must be connected to the MOST network for the subwoofer module (SUB) to function.

FAULT MANAGEMENT ON MOST NETWORK

GENERAL

The MOST network is monitored by the infotainment control module (ICM). If it detects a fault in the MOST network, a diagnostic trouble code (DTC) is stored in the infotainment control module (ICM). There are different types of diagnostic trouble codes (DTCs) depending on the type of fault. A general rule is that if the light pulse in the MOST network disappears, the entire network stops working.

Fault types which are processed are:

- no communication from a control module
- faulty communication on the MOST network.

NO COMMUNICATION FROM A CONTROL MODULE

The infotainment control module (ICM) knows which control modules are connected to the MOST network. If any control module on the MOST network ceases to communicate, a diagnostic trouble code (DTC) is stored in the infotainment control module (ICM). There is a diagnostic trouble code (DTC) for every control module on the MOST network for this fault.

Missing communication may be due to an internal fault in the control module or because the function is incorrectly implemented in the control module.

FAULTY COMMUNICATION

Diagnostic trouble code (DTC) ICM-DC00 is stored in the event of an internal fault in the infotainment control module (ICM) preventing the transmitting and receiving diodes from sending sound pulses on the MOST network.

For faults when messages cannot be sent on the MOST network, diagnostic trouble code (DTC) ICM-DC02 is stored.

Causes of this fault may be that:

- a control module, except the infotainment control module (ICM), has a defective optical connector
- a control module has an internal fault which means that the optical connection stops working
- a control module on the MOST network is not powered. If there is no power supply, the optical connecter stops transmitting light
- the optical cable is damaged or there is an open-circuit. This fault can occur if the bend radius of the cable is too small or if the cable is kinked or trapped
- there is dirt or oil on the optical connectors which impedes the light
- the connection to a control module has come loose
- the fiber optic terminals in the connector are cross-connected
- there is a loose connection because the fiber optical wiring is incorrectly installed or the fiber optic terminal pin has been pressed back in the connector
- a bridging connector has come loose or is damaged.

Ring break diagnostics are used to remedy diagnostic trouble code (DTC) ICM-DC02. If a break is discovered in the MOST network after running a ring break diagnostic, diagnostic trouble code (DTC) ICM-DC01 will be stored in the infotainment control module (ICM). If this is the case, the position of the open-circuit and control module location, can be read off from the infotainment control module (ICM).

RING BREAK DIAGNOSTICS

General

This function is important when fault-tracing the MOST network. Ring break diagnostics are used when there is an open-circuit in the MOST network and diagnostic trouble code (DTC) ICM-DC02 has been stored in the infotainment control module (ICM).

During a ring break diagnostic, all control modules transmit a message to the infotainment control module (ICM) in reverse order to their position on the MOST network. This means that the Subwoofer module (SUB) transmits first, not last.

The control module which is not working will not transmit a response to the infotainment control module (ICM). This also means that the control modules which are connected before the defective control module will be unable to transmit a message to the infotainment control module (ICM).

The same applies in the event of an open-circuit in the fiber optic cable in the MOST network. None of the control modules before the open-circuit will be able to send their message to the infotainment control module (ICM). The infotainment control module (ICM) is then able to calculate the position of the open-circuit from the incoming messages.

HINT: It is important to know which control modules are connected and in what order to identify the control module which sends each message.

Example 1 (up to and incl. structure week 200708)

Fig. 95: Identifying Open-Circuit Between The Remote Digital Audio Receiver (RDAR) And The Audio Module (AUD)
Courtesy of VOLVO CARS CORPORATION

A MOST network contains 6 control modules. There is an open-circuit in the cable between the Remote Digital Audio Receiver (RDAR) and the audio module (AUD). See the illustration.

During the ring break diagnostic, the infotainment control module (ICM) receives responses in reverse order to the order of the control modules on the MOST network.

The Remote Digital Audio Receiver (RDAR), located after the Audio module (AUD) cannot transmit its response to the Infotainment control module (ICM). The infotainment control module (ICM) receives responses up to position four and presents the value 4.

If there was no open-circuit, the infotainment control module (ICM) would have responded "OK.

Example 2 (from and incl. structure week 200709)

Fig. 96: Identifying An Open Circuit Between The Audio Module (AUD) And The Accessory USB Unit (AUU)
Courtesy of VOLVO CARS CORPORATION

A MOST network with all control modules.

An open circuit occurs on the cable between the Audio module (AUD) and the Accessory USB unit (AUU), see figure.

The infotainment control module (ICM) receives responses up to and including the Accessory USB unit (AUU) and presents the value 4.

If there was no open-circuit, the infotainment control module (ICM) would have responded "OK.

MOST NETWORK

GENERAL

MOST (Media Oriented Systems Transport) is a standardized network communication system for multimedia applications. The MOST protocol is optimized for fiber optic communication. This means that signals are sent as light pulses.

MOST DATA

The MOST protocol determines how light pulses or their absence should be interpreted. Each pulse or absent pulse is called a "bit". The number of "bits" transmitted on the MOST network is 24.8 million per second (24.8 Mbit/s).

A bit can be:

- binary 0, i. e. no light pulse

- binary 1, i. e. light pulse.

The light pulses are transmitted in data frames. A data frame consists of different types of data. The size of a data frame is 64 bytes, which is 64 x 8 = 512 bits.

The data frame has a frequency of 48 kHz. This means that 48000 data frames are sent per second on the MOST network.

The data types which are included in a data frame sent on the MOST network are:

- control data
- synchronous data
- asynchronous data
- administrative data.

Control data

Control data is used to check and to allocate the functions to the control modules and the functions in the MOST network.

The control data message is transmitted from, for example, the infotainment control module (ICM) to another specific control module.

The control data message automatically checks if the receiver has received the signal and that the entire message has been correctly transmitted between the transmitting and receiving control modules.

The size of the control data is 2 bytes per data frame. A block, which consists of 16 data frames, is required for a control message to be sent. This means that the total size of the control message is 32 bytes. A control message is the minimum size of a message to activate or deactivate functions on the MOST network.

Examples of MOST messages are track changes or stop commands on the CD player.

Up to 1000 control data messages can be sent per second.

Synchronous data

Synchronous data is used to transmit data which requires considerable quantities of data in real time, for example to play back sound to the Audio Module (AUD).

The length of the synchronous data message which can be sent may be up to 60 bytes per data frame, although never less than 24 bytes. This gives a transfer rate of up to 23 Mbits per second for data transmitted as synchronous data.

Synchronous data shares the data frame with asynchronous data. The infotainment control module controls which control modules transmit synchronous data and which are receivers.

Asynchronous data

Asynchronous data is used to send large quantities of data, such as TCP/IP and digital images, but not in real time.

The length of the message can be up to 36 bytes. This gives a maximum transfer rate of 14 Mbits per second. When the message has been sent, a check is run to ensure that is has been correctly received.

Asynchronous data shares the data frame with synchronous data. The infotainment control module controls which control modules transmit asynchronous data and which are receivers.

Administrative data

Administrative data consists of two parts.

The first part is at the start of the data frame. This describes how much of the transmitted data is synchronous and how much is asynchronous.

The second part is at the end of the data frame. This part checks that the control modules on the MOST network are working correctly.

The size of administrative data is 2 bytes.

MOST DATA FRAME

Fig. 97: Identifying MOST Data Frame
Courtesy of VOLVO CARS CORPORATION

A data frame consists of different parts. This contains for example:

- control data
- asynchronous data
- synchronous data and
- administrative data.

A data frame on the MOST network is 64 bytes. The data frame consists of the following:

1. synchronization of the clock on the MOST network, i. e. the frequency at which data is transmitted so that the data is sent at the correct intervals
2. administrative data, indicates the size of the asynchronous and synchronous data
3. synchronous data
4. asynchronous data
5. control data
6. administrative data.

16 data frames are required to form a block. One block is the minimum size of a MOST message.

MOST PROTOCOL

All activations on the MOST network are control messages or MOST messages. The majority of the MOST messages are initiated by the infotainment control module. The infotainment control module informs certain control modules if a function in the control module must be activated. The infotainment control module then allocates space to transmit data on the MOST network for those activations which have been initiated in the control modules. This is either synchronous or asynchronous data. The structure of a message is as follows:

-

This means:

- - The ID number of one of more control modules in the network
- - the ID number of a function unit, for example the CD function in the Integrated Audio Module
- - ID number to differentiate two identical function units, for example two CD control modules in the MOST network
- - The ID number of the function to be activated, for example play or stop
- - Specifies how the function is to be used, because a function can be used in different ways.

The message may appear as follows:

-

This means: play song number 10 on the CD player in the Integrated Audio Module (IAM).

The infotainment control module (ICM) knows which control modules are in the MOST network. It can then assign specific ID numbers to all control modules and the included functions. If control modules are removed or added, the ID numbers for the control modules are re-assigned.

CALCULATING THE TRANSFER RATE

The number of "ones" and "zeros" transmitted per second determines the transfer rate.

The number of data frames multiplied by the clock frequency of a frame gives the transfer rate.

Example

The maximum transfer rate of asynchronous data:

Bit = a binary 1 or 0

Byte = 8 bit

Maximum asynchronous data = 36 byte

This gives: 36 x 8 = 288 bit

The clock frequency for a data frame = 48 kHz

The maximum number of bits of asynchronous data x clock frequency for a frame: 288 x 48000 = 14 Mbit/s.

SOFTWARE DOWNLOADS ON THE MOST NETWORK

The concept for downloading software is the same as for the CAN network. The CAN uses a PBL (primary boot loader) which is permanently installed in the control module, and a secondary program loading file (SBL - secondary boot loader) which is downloaded into a RAM while the control module is being programmed.

When downloading software for the MOST control modules, a third type of download module is used, GBL (Gateway boot loader). For downloads to the MOST control modules to work, the GBL must be loaded into the infotainment control module (ICM). SBL is used to program the infotainment control module (ICM), in the same way for all other CAN control modules.

GBL downloading

A PROG command is transmitted on the CAN network to all control modules including the infotainment control module (ICM). This command sets all the control modules to reset mode. Before the infotainment control module (ICM) switches to reset mode, it switches off the light to all MOST control modules.

The GBL is then downloaded to a RAM memory in the infotainment control module (ICM). The GBL is then activated and the infotainment control module (ICM) transmits light pulses on the MOST network. The GBL now functions as a connection between the CAN and MOST networks. The GBL sets the MOST control modules to programming mode. All the control modules on the MOST and CAN networks can then be addressed in the same way to download software.

In the event of a total software reload for the control modules on the MOST network, select the MOST network option. Select CAN network for control modules on the controller area network (CAN).

SECURITY ON MOST

This function is used to ensure that all control modules on the MOST network can be used. When the MOST network starts up, ignition position I, II or III, the infotainment control module (ICM) checks that all control modules on the MOST network have approved serial numbers. If the infotainment control module (ICM) detects that one or more control modules do not have approved serial numbers, these modules will be set to disable mode. This means that the control module functions cannot be used in the MOST network. The control module only acts as a conduit for the light pulses.

It takes 30 seconds for the infotainment control module (ICM) to check the control modules. This means that non-approved control modules will be disabled after 30 seconds.

NETWORK DESIGN

GENERAL

Fig. 98: Control Modules In MOST Network
Courtesy of VOLVO CARS CORPORATION

The MOST network is an optical network in which all control modules included are connected in a ring. All messages in the MOST network travel in one and the same direction from the infotainment control module (ICM) to the Subwoofer module (SUB).

In a fiber optic network, light pulses are transmitted instead of electrical signals. The light pulses are interpreted in the same way as the electrical signals on the CAN network.

The MOST network uses the master-slave concept. This means that a master control module, infotainment control module (ICM) has overall control of communication on the MOST network.

The fiber optic cable is made of plastic. Communication is using red light on a wavelength of 650 nm.

THE OPTICAL CONNECTOR

Fig. 99: Identifying Optical Connector
Courtesy of VOLVO CARS CORPORATION

Terminal	Signal type	Miscellaneous
1 / B1	Optical input signal	Input signal for MOST communication
2 / B2	Optical output signal	Output signal for MOST communication

Each control module in the MOST network has an optical connector which consists of two diodes, a sender diode and a receiver diode. These transmit and receive light pulses.

The actual communication between two control modules is as follows. A sender diode transmits the message as a light pulse. This is transmitted from the control module via the MOST network to a photo-optical receiver diode in the receiving control module.

The two optical terminals in the connector are numbered in the same way on all control modules in the MOST network. The size of the plastic housing for the two optical terminals varies. A connector with integrated power supply is integrated with the optical terminals and one connector with only the optical terminals.

MOST COMMUNICATION

All messages are transmitted as light pulses in the same direction on the MOST network. This means that if other control modules are connected between the two control modules which are communicating, the light pulses pass through these with no effect on the information. The control modules which are passed through amplify the light pulse so that it does not become too weak.

A control module with an internal fault can be set to bypass mode. In this mode, the light pulses are sent straight through the control module without the control module amplifying the light pulse. This means that the distance before the light pulse is amplified is longer and therefore the luminance is weaker. If the light pulse is too weak, it cannot be received by the receiving control module.

The infotainment control module (ICM) is the gateway between the MOST and CAN networks for communication to and from control modules connected on the CAN network.

The infotainment control module (ICM) monitors the communication on the MOST network. This involves distributing sound channels on the MOST network, so that sound data can be distributed from, for example, the Remote Digital Audio Receiver (RDAR) to the Integrated Audio Module (IAM). The majority of activations on the MOST network are initiated by the infotainment control module (ICM).

The infotainment control module (ICM) also manages diagnostic trouble codes (DTCs) on the MOST network.

If a control module on the MOST network stops working and is unable to transmit light pulses onwards, or if there is an open-circuit in the fiber optic cable, the entire MOST network will stop working. This means that all the control modules on the MOST network will stop working. For further information about remedying this, see: **FAULT MANAGEMENT ON MOST NETWORK**

The infotainment control module (ICM) must always be connected on the MOST network for communication on the MOST network to work.

The MOST network connections increase and the signal routing may change when control modules are added because adapter wiring is used to connect the new control module.

LOCATION OF CONTROL MODULES ON THE MOST NETWORK

Model year 2007 (up to and incl. structure week 200708)

Fig. 100: Control Modules In MOST Network
Courtesy of VOLVO CARS CORPORATION

Model year 2007 (from and incl. structure week 200709)

Fig. 101: Control Modules In MOST Network
Courtesy of VOLVO CARS CORPORATION

NOTE: **The control modules on the MOST network should be positioned in a particular order. If this order is not followed, troubleshooting of the MOST network will be more difficult.**

When a control module is added to the MOST network, it should be placed in the correct order on the network to make it easier to fault-trace the control modules.

If the control modules are connected in another order, this does not effect the function of the MOST network, but fault-tracing will be more difficult.

Control modules should be placed in the following order (applies to and incl. structure week 200708, model year 2007):

1. Infotainment control module (ICM)
2. The Remote Digital Audio Receiver (RDAR)/Phone module (PHM)

3. Audio module (AUD)
4. Multimedia module (MMM)/Global positioning system module (GPS)
5. Integrated Audio Module (IAM)
6. Subwoofer module (SUB)

Control modules should be placed in the following order (applies from and incl. model year 2007, structure week 200709):

1. Infotainment control module (ICM)
2. The Remote Digital Audio Receiver (RDAR)/Phone module (PHM)
3. Audio module (AUD)
4. Accessory USB unit (AUU)
5. Multimedia module (MMM)/Global positioning system module (GPS)
6. Integrated Audio Module (IAM)
7. Subwoofer module (SUB)

If the minimum configuration of control modules on the MOST network in the car is used, the following control modules are connected:

- infotainment control module (ICM)
- Integrated Audio Module (IAM)

THE NETWORK

GENERAL

The increasing requirements of extended functionality in vehicles has underpinned the development of systems with better performance and more functions. The MOST network is a result of this development.

The MOST network is a fiber optic network which allows a high number of different commands and messages to be sent and received on the same cable and in the same direction.

By using a fiber optic network, functionality is extended without increasing the amount of wiring.

The number of commands and messages which can be handled on the network depends on factors such as the network speed and the length of the message or command. The MOST network which is used in Volvo cars has the capacity to transmit over 300 message types and approximately 1000 messages per second. The transfer rate on the MOST network is approximately 25 Mbit/s.

ADVANTAGES OF AN OPTICAL NETWORK

- electrical short-circuits are not possible on the MOST network. This reduces the risk of damage to control modules connected to the network
- As an optical network, the MOST network does not have problems with EMC (Electro Magnetic

Compatibility)
- the wiring is not sensitive to electrical cross-induction from other wiring
- The transfer speed of the MOST network is much higher than the CAN network
- it is easy to add further functions and to install accessories, known as plug and play units.

The control modules in the network are connected to each other and are constructed so that more functionality can be easily added. All that is required to increase functionality is:

- to connect the sensors to the nearest control module
- to connect the controlled component to the nearest control module
- to download software to change the configuration and programming of the network.

MULTIMEDIA MODULE (MMM) (2003-2006)

DESIGN

CONTROL MODULE

Fig. 102: Locating Multimedia Module (MMM)
Courtesy of VOLVO CARS CORPORATION

A DVD player is integrated in the multimedia module (MMM). The DVD player is used for navigation. The control module has various user functions such as:

- the start menu
- navigation
- system settings.

The start menu displays all the functions available to the user on the screen.

The navigation function in the multimedia module (MMM) calculates the position of the car using the signals from the GPS antenna. The GPS antenna is integrated in the antenna module (ATM).

The multimedia module (MMM) also has a built-in three dimensional piezo-electrical gyro. This supplies information about the movements of the car, such as any turns taken.

Information used from other nodes for navigation:

- the wheel rotation counter from the brake control module (BCM)
- back-up gear position from the transmission control module (TCM) and central electronic module (CEM)
- speed signal from the central electronic module (CEM).

Information from these control modules is transmitted to the infotainment control module (ICM) which then sends the information onwards to the multimedia module (MMM).

The map displayed on the screen indicates the position of the car. This position is adjusted using information from:

- the wheel rotation counter
- the speed signal
- the gyro in the multimedia module (MMM)
- the back-up gear position
- the GPS antenna
- the map matching function.

Information from the gyro and wheel rotation counter can be used for dead reckoning (i. e. to calculate the position). This happens for example when communication with the GPS satellites is lost such as when traveling through a tunnel.

The multimedia module (MMM) receives traffic information messages (TMC) from the antenna module (ATM) via the MOST network. This information is displayed on the directly connected display screen. The traffic message channel (TMC) is a standardized code system for traffic messages. It provides information about road works, heavy traffic etc. The Japanese equivalent of TMC is called FM multiplex. This system is not available in the USA.

The navigation function also includes voice guiding which instructs the driving how to reach the set destination.

The user can configure certain functions in the system settings. These functions are:

- date and time
- user settings, such as password.

The following functions are displayed on the directly connected display screen:

- navigation.

The control module transmits all the signals required to control the display screen.

The multimedia module (MMM) uses the Windows CE operating system.

DISPLAY SCREEN

Fig. 103: Identifying Display Screen
Courtesy of VOLVO CARS CORPORATION

Functions such as Mobile office, system settings and navigation are presented on a 6.5" display screen in the center of the dashboard. The display screen is directly connected to the multimedia module (MMM). The control module transmits all the signals required to control the display screen.

If there is an internal fault in the screen or faults in communication with the control module, the quality of the display on the screen will deteriorate or the screen will stop working completely. A simple way to detect a fault in the screen, or communication problems between the screen and the control module, is to check the appearance of the image on screen.

The menu system on the display screen can be controlled either using the navigation buttons on the reverse of the steering wheel or using the screen remote control. The infra-red receiver for the remote control is on the infotainment control module (ICM).

DIAGNOSTIC FUNCTIONS

GENERAL

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. A fault which is detected in the most recent operating cycle is defined as permanent. Other faults are defined as intermittent.

Should a fault disappear for any reason after being permanently stored in the control module as a diagnostic trouble code (DTC), the information remains stored in the control module.

If a fault is no longer permanent, the diagnostic trouble code (DTC) remains as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

NOTE: Certain functions are unavailable until the diagnostic trouble codes (DTCs) have been erased.

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N.

READING OFF EXTENDED FAULT-TRACING INFORMATION

This function can be used to read parameters, status identifiers and counters stored at the same time as a diagnostic trouble code (DTC). These are called frozen values.

For further information, see **DESCRIPTION OF VEHICLE COMMUNICATION INFORMATION** .

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the multimedia module (MMM). When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

All the software required for the traffic information system to work in the control module is on the DVDs.

The control module is under the left front seat.

After replacing the control module, the unique serial numbers of the control module are checked by the infotainment control module (ICM). The installed control module will not work if the serial number is incorrect.

Try turning the ignition off and on if there are problems after the software is downloaded and the control module is not working.

The MOST network is used for a total software reload.

FUNCTION

MENU CONTROL OF THE MULTIMEDIA MODULE (MMM)

The on-screen menu can be controlled using the buttons on the reverse of the steering wheel.

The buttons consists of:

- a Back button
- an Enter button
- a navigation button which is used to move the cursor up, down, left and right on the screen.

These commands are transmitted from the steering wheel module (SWM) (3/130) to the infotainment control module (ICM) (16/1) via the Controller area network (CAN). The infotainment control module (ICM) converts the electrical signal to an optical signal and sends it onwards to the multimedia module (MMM) (16/108) via the MOST network.

The remote control for the multimedia module (MMM) has the same functions as the steering wheel buttons. The remote control can be used to control the menus on the display screen. An infra-red signal is transmitted from the remote control to an infra-red receiver on the infotainment control module (ICM), which in turn sends the signal on to the multimedia module (MMM) on the MOST network.

NAVIGATION

Fig. 104: Identifying Navigation Network
Courtesy of VOLVO CARS CORPORATION

The navigation function displays the location of the car and directions to the entered destination.

The navigation buttons on the steering wheel module (SWM) (3/130) are used to control the on-screen menu for

navigation.

The multimedia module (MMM) (16/108) receives GPS signals from the antenna module (ATM) (16/110) via the MOST network.

Two signals are transmitted via the high speed side of the Controller area network (CAN) to the central electronic module (CEM) (4/56):

- information about the wheel rotation counter is transmitted from the brake control module (BCM) (4/16)
- information about the back-up gear position is transmitted from the transmission control module (TCM) (4/28).

The central electronic module (CEM) transmits both signals to the infotainment control module (ICM) (16/1) via the low speed side of the Controller area network (CAN). The vehicle speed is also transmitted to the infotainment control module (ICM) from the central electronic module (CEM). This in turn sends the signals on to the multimedia module (MMM) on the MOST network.

Information for voice guiding for the selected destination is transmitted on the MOST network between the multimedia module (MMM) and the audio module (AUD) (16/105).

A DVD with the required road network must be installed in order for the multimedia module (MMM) to select a route and display the position of the car. The multimedia module (MMM) is then able to calculate the position and display it on the directly connected screen (16/46).

SYSTEM OVERVIEW

MULTIMEDIA MODULE (MMM)

The multimedia module (MMM) is an optional control module. Its primary task is to manage the functions for:

- navigation
- Traffic message channel (TMC)
- FM multiplex (Japan only)
- display screen
- DVD player.

Only the display screen is directly connected to the multimedia module (MMM). The DVD player is integrated in the multimedia module (MMM). The functions from other control modules are via the MOST network, but are managed using the multimedia module (MMM). The system is not compatible with music CD or DVDs.

The multimedia module (MMM) uses the MOST network to communicate with other control modules.

The control module checks activations and input and output signals via an integrated diagnostic system. A diagnostic trouble code (DTC) is stored if the control module detects a fault. Any diagnostic trouble codes (DTCs) are stored in the control module memory. This information can be read off using VIDA via the data link connector (DLC) in the car.

In order to work correctly on the MOST network, the infotainment control module (ICM) checks that the serial number in the multimedia module (MMM) is correct. The multimedia module (MMM) will not function if the number is incorrect. Try switching the ignition off and on if there are problems when replacing the control module.

A simple way to ensure that the multimedia module (MMM) is powered is to insert and then remove a DVD. If this does not work, check that the unit is powered and grounded.

The multimedia module (MMM) is under the left front seat.

SIGNALS

The table below summarizes the input signals to and output signals from the multimedia module (MMM). The signal types are divided into directly connected signals and MOST communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected:	**Directly connected:** (power supply unless otherwise stated) • Display screen (16/46) (color and synchronizing signals).
Via MOST communication: (ring network) • Infotainment Control Module (ICM) (16/1) master control module • Audio module (AUD) (16/105) • Phone module (PHM) (16/60) • Antenna module (ATM) (16/110).	**Via MOST communication:** (ring network) • Infotainment Control Module (ICM) (16/1) master control module • Audio module (AUD) (16/105) • Phone module (PHM) (16/60) • Antenna module (ATM) (16/110).

Fig. 105: Identifying Volvo Component Designations
Courtesy of VOLVO CARS CORPORATION

MULTIMEDIA MODULE (MMM) (2007-2012)

DESIGN

CONTROL MODULE

Fig. 106: Locating Multimedia Module (MMM)
Courtesy of VOLVO CARS CORPORATION

The Multimedia module (MMM) has a hard disk and a DVD player integrated in the control module. The DVD player is used to upgrade the software in the Multimedia module (MMM) and transfer map information from the DVD to the hard disk. Using the hard disk obtains the map information quicker and makes storing more data possible. The map information is used for navigation.

The Multimedia module (MMM) has an integrated gyro that manages information about the vehicle's direction of travel.

The multimedia module (MMM) as inputs and outputs for:

- power supply
- ground
- GPS
- TMC
- RGB output to the screen
- MOST network

GPS

Information to the GPS unit consists of signals received from GPS satellites via the GPS antenna.

The navigation system requires at least three satellites to be able to calculate the vehicle's position.

Power is supplied to the GPS unit from the multimedia module (MMM). The GPS unit is integrated in the multimedia module (MMM).

NOTE: **If the GPS signal is diagnosed as missing, the signal should be checked outdoors in an open area as the signal could be blocked if the vehicle is indoors and surrounding buildings could interfere with reception of GPS signals. It can take up to 12 minutes until the GPS signal has been captured and the position has been determined.**

TMC

The TMC signal is transmitted from the antenna amplifier and received by the TMC receiver. The TMC signal is managed in the Multimedia module (MMM) and the information is then presented on the display screen.

The TMC receiver is integrated in the multimedia module (MMM).

TMC is a standardized code system for traffic bulletins, such as information on road construction. TMC is only available on certain markets.

SCREEN

Fig. 107: Identifying Display Screen
Courtesy of VOLVO CARS CORPORATION

Functions such as system settings and navigation are presented on the display screen in the center of the dashboard. The Multimedia module (MMM) transmits RGB signals to the display screen.

If there is an internal fault in the screen or faults in communication with the control module, the quality of the display on the screen will deteriorate or the screen will stop working completely. A simple way to detect a fault in the screen, or communication problems between the screen and the control module, is to check the appearance of the image on screen.

The screen's menu system can be controlled with the navigation keys on the back of the steering wheel or with the remote control for the screen.

The infra-red receiver for the remote control is in the infotainment control module (ICM) (just under the volume knob). The infra-red receiver at the upper edge of the monitor is not active.

DIAGNOSTIC FUNCTIONS

GENERAL

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

If the control module detect a fault, a diagnostic trouble code (DTC) is stored. A fault that was detected during the last operating cycle is defined as permanent. Other faults that are detected are defined as intermittent.

Should a fault disappear for any reason after being stored in the control module as a permanent diagnostic trouble code, the information remains stored in the control module. If a fault is no longer permanent, the diagnostic trouble code remains as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes can only be erased once all the diagnostic trouble codes have been read out at least once.

NOTE: Certain functions are unavailable until the diagnostic trouble codes (DTCs) have been erased.

READING OFF THE PARAMETERS

This function is used to read the status or value of parameters. The status or value can be presented digitally.

ACTIVATING COMPONENTS AND FUNCTIONS

This function can be used to activate components and functions that affect the multimedia module (MMM).

READING OFF THE CONTROL MODULE IDENTIFICATION

The diagnostic tool identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N

READING OFF EXTENDED FAULT-TRACING INFORMATION

This function can be used to read out parameters, identify status and counts stored at the same time as a diagnostic trouble code (known as frozen values).

DOWNLOADING SOFTWARE, MAP UPDATING AND REPLACING THE CONTROL MODULE

SOFTWARE DOWNLOADING

The DVD is used to upgrade the application software in the multimedia module (MMM).

MAP UPDATING

Map information is updated by inserting a new DVD with updated map information in the DVD player. The map information is transferred onto the hard disk in the Multimedia module (MMM).

When the map information has been updated, the DVD must be in the DVD player in order for the map information to be displayed.

REPLACING THE CONTROL MODULE

The Multimedia module (MMM) is installed under the left-hand front seat.

The Multimedia module (MMM) is preloaded with application software and map information.

When replacing the Multimedia module (MMM), software must also be downloaded via Volvo's central database to be able to write the new serial number to the Central electronic module (CEM).

After replacement of the multimedia module (MMM), the infotainment control module (ICM) checks its unique serial number. If the serial number is incorrect, the multimedia module (MMM) will not work. If the problem remains after software download, try switching the ignition off/on.

FUNCTION

CONTROL MODULE

Fig. 108: Locating Multimedia Module (MMM)
Courtesy of VOLVO CARS CORPORATION

The DVD player is used to transfer map information to the hard disk. The map information on the hard disk is used to navigate. The Multimedia module (MMM) has several user functions, such as:

- route guidance, i. e. guidance to a specific target (address, a specific hotel etc.)
- show map
- find a hotel, a car park, a shopping mall, in the surroundings or in the vicinity of a specific place
- show TMC information, i. e. traffic information (traffic jams, closed roads etc.)
- show remaining mileage and estimated journey time to selected destination.
- system settings for navigation

The start menu allows the user to choose whether the system is to start in a Beginner or Advanced user setting. In the Beginner user setting, only the most important functions are available and are intended for beginners. All functions are available in the advanced user setting

The navigation menu and quick menu display, on the monitor, all the functions that are available for the user to use.

Certain functions can be configured by the user in system settings. These functions are:

- type of route guidance (fastest route, shortest route or easiest route)
- avoid ferries, toll roads etc or not
- volume voice guidance
- language.

MENU NAVIGATION

Fig. 109: Networking Diagram
Courtesy of VOLVO CARS CORPORATION

The on-screen menu can be controlled using the navigation buttons on the reverse of the steering wheel (16/46).

The buttons consist of:

- an enter button
- a back button
- a control button that can move the marker on the screen up, down, left and right.

The commands are transmitted from the Steering wheel module (SWM) (3/254) via LIN to the Central electronic module (CEM) and on to the Infotainment control module (ICM) (16/94) on the CAN network. The Steering wheel module (SWM) converts the electrical signal to an optical signal and sends it onwards to the multimedia module (MMM) (16/108) via the MOST network.

The remote control for the Multimedia module (MMM) has the same functions as the steering wheel buttons.

NAVIGATION

Fig. 110: Networking Diagram
Courtesy of VOLVO CARS CORPORATION

The navigation section in the Multimedia module (MMM) (16/108) calculates the vehicle's position from the information from:

- GPS antenna
- wheel rotation counter
- the gyro in the multimedia module (MMM)
- reverse gear status
- map matching function.

Information from other nodes that is used for navigation:

- wheel rotation counter from the brake control module (BCM) (4/16)
- reverse gear status from the transmission control module (TCM) (4/28) and central electronic module (CEM) (4/56)

Information from these control modules is sent to the infotainment control module (ICM) (16/94), which then distributes the information to the multimedia module (MMM).

Information from the gyro and the wheel rotation counter is used to achieve better precision than the GPS

position from the GPS antenna can give, and is used for dead reckoning, i. e. to calculate the position when communication is lost with the GPs satellites. This occurs when in a tunnel, for example.

The navigation function indicates current position and how to get to the specified destination. There is also voice guidance, which tells the driver which way to drive to get to the specified destination.

The navigation buttons on the steering wheel module (SWM) (3/254) are used to control the on-screen menu for navigation.

Two signals are sent via the high speed side of the CAN network to the central electronic module (CEM):

- information from the wheel rotation counter is sent from the brake control module (BCM)
- information on reverse gear status is sent from the transmission control module (TCM)

The central electronic module (CEM) transmits both signals to the infotainment control module (ICM) via the low speed side of the Controller area network (CAN). In turn, it sends the signals on the MOST network to the Multimedia module (MMM).

Information for voice guidance to the selected destination is sent between the multimedia module (MMM) and integrated audio module (IAM) (16/1) via the MOST network.

In order for the Multimedia module (MMM) to select a route and display the position of the car, the map information must be on the hard disk. The Multimedia module (MMM) calculates the position and displays it on the directly connected screen. If the map information has been updated, the DVD must be left in the DVD player, otherwise the map information will not be displayed.

GPS RECEPTION

Fig. 111: Networking Diagram
Courtesy of VOLVO CARS CORPORATION

The multimedia module (MMM) (16/108) receives GPS signals from the GPS antenna (16/64) to the integrated GPS unit for position determination.

The information about the vehicle's position is continuously transmitted from the Multimedia module (MMM) via the MOST network to the Phone module (PHM) (16/60) for the Volvo On Call function.

A telephone number can also be sent from the Multimedia module (MMM) via the MOST network to the Phone module (PHM), to make a call to a hotel for example.

TMC RECEPTION

Fig. 112: Networking Diagram
Courtesy of VOLVO CARS CORPORATION

The multimedia module (MMM) (16/108) receives traffic information messages (TMC) via the TMC receiver. The signal is transmitted via the antenna amplifier. Traffic information messages (TMC) are displayed on the display screen (16/46).

TMC is a standardized code system for traffic bulletins, such as information on road construction.

The information is displayed on the monitor and is also used by the navigation function during guidance, to avoid closed roads and navigate around queues if possible (dynamic route guidance).

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 113: Locating Multimedia Module (MMM)
Courtesy of VOLVO CARS CORPORATION

The multimedia module (MMM) is an optional module. Its most important task is handling the functions for:

- navigation
- TMC
- GPS
- RGB output for the screen
- DVD player

The GPS unit and the TMC receiver are integrated in the Multimedia module (MMM). The monitor is directly connected to the Multimedia module (MMM). The DVD player is integrated in the Multimedia module (MMM). The Multimedia module (MMM) has a hard disk where map information is stored.

Map data that is stored on the hard disc is updated via the DVD player.

Other functions come from the control modules on the MOST network, but are managed using the Multimedia module (MMM). The system cannot handle CDs or DVDs containing music or films.

The multimedia module (MMM) communicates with other control modules via the MOST network.

The control module checks internal components, executed activations and input/output signals via its integrated diagnostics. If the control module detects a fault, a diagnostic trouble code is generated. Any diagnostic trouble codes are stored in the control module memory. The information can be read via the data link connector in the vehicle.

In order to work in the MOST network, the infotainment control module (ICM) checks that the central electronic module (CEM) has the correct serial number for the multimedia module (MMM). If the number is incorrect, the multimedia module (MMM) will not be operable. If a problem arises upon control module replacement, try switching the ignition off/on.

A simple way to check that the Multimedia module (MMM) is supplied with power is to insert and eject a

DVD. The check requires the ignition to be in ignition position II. If this does not work, first check that the unit is powered and grounded.

The Multimedia module (MMM) is installed under the left-hand front seat.

SIGNALS

The table below summarizes the input signals to and output signals from the multimedia module (MMM). The signal types are divided into directly connected signals and MOST communication. The illustration below depicts the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: • Power supply • Ground • GPS signal from GPS antenna (16/64) • TMC signal from antenna amplifier (16/71)	**Directly connected:** • Display screen (16/46) (color and synchronizing signals)
Via MOST communication: • Infotainment control module (ICM) (16/94) (brake control module (BCM) and transmission control module send signals to infotainment control module (ICM) via CAN network).	**Via MOST communication:** • Infotainment control module (ICM) (16/94) • Integrated audio module (IAM) (16/1) • The Phone module (PHM) (16/60) (call to point of interest (POI), the vehicle's position to the Volvo On Call service)

Fig. 114: Identifying Volvo Component Designations
Courtesy of VOLVO CARS CORPORATION

OVERVIEW BRAKE SYSTEM (2003-2012)

BRAKES

OVERVIEW BRAKE SYSTEM

Fig. 115: Identifying Brake System Components
Courtesy of VOLVO CARS CORPORATION

RSC (Roll Stability Control)

The Volvo XC90 has an active system which counteracts any tendency to roll over, and gives the vehicle stability during violent avoidance maneuvers.

If there is a risk of the car turning over, RSC is activated. This function is integrated in DSTC (Dynamic Stability and Traction Control). It lowers the engine torque and stabilizes the vehicle by braking one or more wheels.

Foot controlled parking brake

The parking brake is applied by pressing the pedal on the floor. The handle in the light switch module (LSM) is used to release the parking brake.

Vacuum pump

B6294T has an electrical vacuum pump to ensure that the pressure is stable in the power brake booster.

- The vacuum switch is on the power brake booster side
- The switch is controlled via the system relay for the engine control module (ECM) and is connected in series to the vacuum pump.

General

For 17 " wheels, the diameter of the brake discs is 316 mm at the front and 308 mm at the rear.

New brake pads, more environmentally friendly. Lead free.

FOOT CONTROLLED PARKING BRAKE

Fig. 116: Viewing Foot Controlled Parking Brake
Courtesy of VOLVO CARS CORPORATION

1. Cable holder, cable to the brake shoes
2. Parking brake switch
3. Cable holder, cable to the handle
4. Parking brake pedal
5. Release handle.

The parking brake is mechanical and acts on the brake shoes in the brake drum on the rear wheels.

The brake pedal is operated when the driver presses the pedal.

The handle in the light switch module (LSM) is used to release the parking brake.

The switch for the parking brake warning lamp is on the mechanism for the parking brake.

The foot controlled mechanism has an integrated adjuster function.

The parking brake pedal is located,

- on the left-hand side at floor height

RSC (ROLL STABILITY CONTROL)

Fig. 117: Identifying Roll Stability
Courtesy of VOLVO CARS CORPORATION

The Volvo XC90 has an active system which counteracts roll over, and increases the vehicle stability during violent avoidance maneuvers.

An integrated gyroscope in the DSTC cluster calculates the dynamic angle of lean and therefore the risk of roll over.

If there is a risk of the car turning over, RSC is activated. This function is integrated in DSTC (Dynamic

Stability and Traction Control). It lowers the engine torque and stabilizes the vehicle by braking one or more wheels.

- The RSC function cannot be disabled
- RSC is activated at speeds above 10 km/h
- In RSC mode, the all-wheel drive (AWD) function is disengaged via the differential electronic module (DEM).

RSC, basic principles

Fig. 118: Identifying Roll Causes
Courtesy of VOLVO CARS CORPORATION

There are number of factors which could cause a wheel to leave the ground.

Caused by an obstacle. (Tripped roll-over):

- the inner wheels hit a raised surface on the road. (1a)
- if the outer wheels hit a fixed object in a corner. (1b).

Caused by friction when cornering. (Un-tripped roll-over):

- the vehicle speed is too high in relationship to the radius of the corner. (2a).

Basic criteria for RSC to activate,

- the vehicle is traveling at a speed in excess of 10 km/h
- one or more wheels is off the ground.

Note that when carrying heaving loads on the roof, the risk of roll over increases when taking sharp corners. (2b)

Overview sensor(s) for RSC

Fig. 119: Identifying RSC Sensors
Courtesy of VOLVO CARS CORPORATION

1. Steering wheel angle sensor
2. Steering wheel angle sensor (SAS)
3. Cluster
4. Wheel sensor, front
5. Wheel sensor, rear
6. Brake control module (BCM)
7. Power brake booster housing
8. Brake pressure sensor

9. Brake pressure sensor
10. Pedal position sensor
11. Warning lamp
12. DSTC switch.

RSC is included in the same cluster as DSTC. The cluster is located under the right-hand seat.

The RSC function cannot be disabled using the DSTC button.

When switching off the DSTC switch, only the SC (Stability Control) function is disengaged.

PARKING ASSISTANCE CAMERA (PAC) (2007-2012)

DESIGN

CONTROL MODULE

Fig. 120: Identifying Parking Assistance Control Module
Courtesy of VOLVO CARS CORPORATION

The Parking Assistance Camera (PAC) is located on the left-hand side of the cargo compartment, on top of the Trailer module (TRM). The Parking Assistance Camera (PAC) is equipped with three connections. One to the video camera, one to the video output and a CAN connection.

The Parking Assistance Camera (PAC) uses the connection to the camera to send control signals to the camera via LIN communication, receive LVDS video signals and to supply the camera with power.

The video output is used to transfer the NTSC video composite signal to the display screen via T connection on the Multimedia module (MMM).

The CAN connection is used to receive necessary signals from the Steering wheel angle sensor module (SAS), Central electronic module (CEM) and Brake control module (BCM).

The Parking Assistance Camera (PAC) is activated in ignition position II, when reverse is engaged. When the

Parking Assistance Camera (PAC) is active, the camera is also active.

Parking Assistance Camera (PAC) switches off:

- ignition positions greater than II
- if the ignition position is less than II for longer than 15 seconds
- when reverse gear is disengaged for longer than 30 seconds.

Multimedia module (MMM) switches off:

- when reverse gear has been disengaged for longer than 15 seconds
- or if the speed exceeds 10 km/h.

Logic for display screen

The display screen is controlled by the Multimedia module (MMM) and the screen is controlled by the Parking Assistance Camera (PAC).

When the navigation system is not active the following applies:

- The display screen goes up and the Parking Assistance Camera (PAC) displays images when reverse is activated in ignition position II.
- When reverse is disengaged, the display screen is up displaying images for 15 seconds. If the vehicle speed is greater than 10 km/h during these 15 seconds, the display screen goes down. If the navigation system is activated during these 15 seconds, these images are displayed instead.

When the navigation system is active the following applies.

- The Parking Assistance Camera (PAC) displays images when reverse gear is activated in ignition position II.
- When reverse gear is disengaged, the parking camera image is displayed for 15 seconds. If the vehicle speed is greater than 10 km/h during these 15 seconds, images from the navigation system are displayed. If the switch for activating the navigation system is pressed during these 15 seconds, the navigation system image is displayed instead.

CAMERA

Fig. 121: Identifying Parking Assistance Camera (PAC)
Courtesy of VOLVO CARS CORPORATION

The camera is located in the tailgate, slightly to the right of the handle.

After installing a new camera, it must be set so that the help lines are displayed in the correct place on the screen. This is carried out using a check procedure in Volvo's diagnostic tool. By activating the check procedure, the view of the camera is displayed on screen with a general semi-transparent pattern that should match the contour of the bumper, at the lower edge of the image.

The camera is only activated when the Parking Assistance Camera (PAC) is activated.

DIAGNOSTIC FUNCTIONS

GENERAL

The Parking Assistance Camera (PAC) does not have a built-in diagnostic system. In the event of a fault in any of the components that are required to generated or transmit image information from the camera to the display screen, a black screen is shown instead. It is only shown if the fault occurs when the Parking Assistance Camera (PAC) is activated, and is only shown once.

ACTIVATING COMPONENTS

This function can be used to activate components to check that they are working.

READING OFF THE CONTROL MODULE IDENTIFICATION

The diagnostic tool identifies control modules by reading off a number of codes from the control module memory.

The codes contain the following information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N

- diagnostic software P/N (part of the software).

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded to the Parking Assistance Camera (PAC).

When ordering software the vehicle's hardware and software are compared with Volvo's central database. If the comparison is correct the software is downloaded to the control module.

If the comparison between the car and Volvo's central database does not correspond, then the database is updated with the vehicle's configuration. When this is complete the software is downloaded.

FUNCTION

MENU SYSTEM

Fig. 122: Identifying Parking Assistance Camera (PAC) Network
Courtesy of VOLVO CARS CORPORATION

The signal with information about which gear is engaged is transmitted via the CAN network from the Central electronic module (CEM) (4/56) to the Parking Assistance Camera (PAC) (4/120) and Infotainment control module (ICM) (16/94). The Infotainment control module (ICM) transmits, in turn, the signal onwards via the MOST network to the Multimedia module (MMM) (16/108).

The Steering wheel angle sensor module (SAS) (3/254) transmits information about the steering wheel angle, via the CAN network, to the Central electronic module (CEM), which transmits the information on to the Parking Assistance Camera (PAC).

The Brake control module (BCM) (4/16) transmits signals about the speed via the CAN network to the Central electronic module (CEM), which transmits the signal onwards to the Infotainment control module (ICM) and the Parking Assistance Camera (PAC). The Infotainment control module (ICM) transmits, in turn, the signal onwards via the MOST network to the Multimedia module (MMM).

The Parking Assistance Camera (PAC) controls the camera (27/6) via LIN communication. The camera transmits a LVDS video signal to the Parking Assistance Camera (PAC). The Parking Assistance Camera (PAC) converts this signal to an NTSC video signal, which is transmitted to the display screen, via a T connector on the Multimedia module (MMM).

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 123: Identifying Parking Assistance Control Module
Courtesy of VOLVO CARS CORPORATION

The task of the Parking Assistance Camera (PAC) is to facilitate parking. When reverse is engaged, the Parking Assistance Camera (PAC) is activated. An image on the display screen then shows what is behind the vehicle. The display screen also shows help lines that correspond to a distance of 0.3 and 1.5 m backwards. At right-angles to these help lines are lines that show the lateral position of the vehicle. If the steering wheel is moved, the help lines move to the lateral position of the vehicle.

The camera is located in the tailgate and the control module is located on the left-hand side of the cargo compartment.

The Parking Assistance Camera (PAC) communicates both with directly connected components via LIN communication and with other control modules via CAN communication.

The control module does not have integrated diagnostics, instead a black screen is shown in the event of a system fault.

The Parking Assistance Camera (PAC) and corresponding video camera can be replaced separately.

To check that the Parking Assistance Camera (PAC) is powered and grounded, ignition position II can be activated and reverse engaged when stationary. If the display screen rises and shows an image of what is behind the vehicle, the Parking Assistance Camera (PAC) is powered.

SIGNALS

The table below summarizes the input signals to and output signals from the Parking Assistance Camera (PAC). The signal types are divided into directly connected signals, LIN communication and controller area network (CAN) communication. The illustration below displays the same information with the Volvo component designations.

Input signals:	Output signals:

PHONE MODULE (PHM) (2006-2012)

DESIGN

PHONE ANTENNA

Fig. 125: Viewing Phone Antenna
Courtesy of VOLVO CARS CORPORATION

The phone antenna is directly connected to the phone module (PHM).

The phone antenna is located in the windshield in front of the rear view mirror.

There are diagnostics for the antenna.

HANDSET (MODEL YEAR-DEPENDENT)

Fig. 126: View Of Handset
Courtesy of VOLVO CARS CORPORATION

The handset is directly connected to the phone module (PHM). The handset is located in the center console.

The phone module (PHM) determines if the call is to be connected via handsfree or handset from the click signal of the handset. When the handset is in the holder all calls are connected via handsfree. The handset is activated when it is removed from the holder. Note that voice calls do not go via the handset if it is lifted when an incoming call arrives or when an out going call is started using the ENTER button. The handset must be replaced and then lifted again for conversations via the handset. The reason for this is to avoid missing sound when the handset has been lifted accidentally. The click signal to the phone module (PHM) is controlled by a magnetic switch placed in the handset. The switch is closed by the magnet in the handset. When the handset is in the holder the click signal to the phone module (PHM) is 0 V, when the handset is used the signal is 5 V.

There are diagnostics for the handset.

SIM CARD HOLDER

Fig. 127: Identifying Sim Card Holder
Courtesy of VOLVO CARS CORPORATION

The holder for the customer's private SIM card is located in the key pad for the infotainment control module (ICM). The SIM card holder is serially connected to the phone module (PHM).

There are diagnostics for the SIM card holder.

SWITCH FOR VOLVO ON CALL

Fig. 128: Identifying Switches
Courtesy of VOLVO CARS CORPORATION

The switches for ON CALL and SOS are located in the instrument panel under the switch for the hazard warning signal flashers. The switches are only for the phone module (PHM) with the Volvo On Call functionality.

The switches are directly connected to the phone module (PHM).

Voltage supply and grounding of the switch lighting is via the phone module (PHM). The level of the light strength is adjusted using a pulse width modulated (PWM) signal.

There are diagnostics for the switches.

DIAGNOSTIC FUNCTIONS

GENERAL

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

If the control module detects a fault, a diagnostic trouble code is generated. The number of diagnostic trouble codes (DTCs) totals approximately 29. A fault that is detected during the most recent operating cycle is defined as permanent. Other faults that are detected are defined as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N.

READING OFF EXTENDED DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION

This function can be used to read parameters, status identifiers and counters stored at the same time as a diagnostic trouble code (DTC). These are called frozen values.

READING OFF THE PARAMETER VALUES

Using this service the status or value of parameters can be read out. The status/value is presented digitally.

REINSTALLING THE RESERVE BATTERY

This service can reset the value to 100% when the reserve battery has been replaced. After replacing the reserve battery in the phone module (PHM) with Volvo On Call functionality the battery algorithm must restored.

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

GENERAL

New software can be downloaded to the phone module (PHM). When ordering software the vehicle software and hardware are compared to Volvo's central database. If the comparison corresponds the new software is downloaded to the control module.

If the comparison between the vehicle and the Volvo central database does not correspond, the database is updated with the vehicle configuration, and then the software and any security codes (Security access code) is downloaded.

The phone module (PHM) is located behind the center console.

REPLACING PHONE MODULE (PHM) WITH VOLVO ON CALL

In addition to the software for the phone module (PHM) with Volvo On Call functionality, a unique security code is also downloaded with the software. When replacing the phone module (PHM) the security code is retrieved from the Volvo central database. A new phone module (PHM) has a generally known security code. The code is used to unlock the control module, and to program functions and to read off parameters. Unlocking is carried out automatically in the ordering version accessible in VIDA (Volvo scan tool).

After software download the read off parameters are transmitted to the Volvo central database. Information about modification to the customer data for Volvo On Call are then transmitted further from the Volvo central database to the web portal that handles customer data for Volvo On Call. The information is also transmitted to the Volvo On Call Service Center via ftp (File Transfer Protocol).

The unique security code is programmed into the phone module (PHM) during software download.

The following parameters are read off and transmitted to the Volvo central database:

- GSM number for the subscription
- The security code for the unit (Security access code)
- The PUK code for the internal SIM card for Volvo On Call
- IMEI (International Mobile Equipment Identity), GSM unit serial number
- Version number on the GSM unit software
- Unit type.

NOTE: After replacing the phone module (PHM), the Volvo On Call functionality must be activated if the customer has an active subscription. This does not happen automatically during the order process.

Volvo On Call is activated either via software orders or via the keypad on the Infotainment control module (ICM). After the Volvo On Call functionality is activated, the phone module (PHM) will wait for information about the position of the vehicle for 0.5-20 minutes. The position is sent from the Aerial module (ATM) (-2006) or Multimedia module (MMM) (2007-), the MOST network. During this time, the car must be parked outdoors with no large obstacles, which could prevent the Aerial module (ATM) (-2006) or Multimedia module (MMM) (2007-) from establishing contact with the GPS satellites, obscuring it. If the phone module (PHM) is unable to receive a position within this time, the activation sequence will be cancelled. Volvo On Call Plus functionality switches to deactivated. After the phone module (PHM) has obtained the position of the car, the ON CALL button must be held in for at least two seconds to connect a voice call the Volvo On Call Service Center. This call is made to confirm the new vehicle data and to check that Volvo On Call is functioning correctly.

Because of the unique security code and the internal SIM card a phone module (PHM) with Volvo On Call functionality cannot be swapped from one vehicle to another.

ACTIVATING AND DEACTIVATING VOLVO ON CALL

It is also possible to activate or deactivate the Volvo On Call function by downloading software. The security access code must be retrieved from the Volvo central database. It is also possible to activate/deactivate the functionality via menu management. The instructions and activation code for this are available at the Volvo On Call ' web site. If necessary (misuse of Volvo On Call for example) the network operator can cancel the subscription of the internal SIM card for Volvo On Call. After activation of the Volvo On Call functionality the same applies as for replacing a control module as regards searching for GPS satellites and connecting calls to the Volvo On Call Service Center.

If the Volvo On Call functionality is deactivated the user will be informed by text message. The text message will be displayed in the driver information module (DIM) at the start of every driving cycle (key position I).

FUNCTION

PHONE

Fig. 129: Identifying Phone Network
Courtesy of VOLVO CARS CORPORATION

When using the menu via the steering wheel buttons (3/131) information is transmitted from the steering wheel module (SWM) (3/254) to the infotainment control module (ICM) via the CAN network. The information is then transmitted to the phone module (PHM) via the MOST network.

Menu management is displayed for the user in the display for the infotainment control module (ICM). Information is transmitted from the phone module (PHM) to the infotainment control module (ICM) via the MOST network.

When starting the phone module (PHM), receiving incoming calls or when using the phone, a request to use the display will be transmitted to the infotainment control module (ICM).

Phone calls can be connected via handsfree or the handset. The phone module (PHM) for the XC90 does not have a separate microphone or loudspeaker for handsfree.

For calls via handsfree the microphone and loudspeaker connected to the audio module (AUD) (16/105) are used. The phone module (PHM) transmits a request to the infotainment control module (ICM) to get access to the microphone and loudspeaker that are connected to the audio module (AUD).

VOLVO ON CALL

Model year -2006

Fig. 130: Identifying Volvo On Call Network
Courtesy of VOLVO CARS CORPORATION

Model year 2007-

Fig. 131: Identifying Volvo On Call Network
Courtesy of VOLVO CARS CORPORATION

Volvo On Call is a system developed by Volvo where the owner has access to different services for safety and service. The service is based on the passenger or driver being able to contact a Volvo On Call Service Center by phone. The personnel at the service center, decide what action to take, depending on the circumstances. Using the information from the On Call system, including the exact position of the vehicle, the service center can quickly direct ambulance, police and recovery vehicles to the vehicle. The different services provided can be separated into two groups, service and safety.

A Volvo On Call service can be activated in one of the following ways:

- by the customer via the switches for Volvo On Call (3/267)
- by the Volvo On Call Service Center
- by the vehicle system.

The strength of the lighting in the switches for Volvo On Call is controlled via the rheostat controls in the light switch module (LSM) (3/111).

Phone module (PHM) (16/60) receives the rheostat signal from the central electronic module (CEM) (4/56) via infotainment control module (ICM) (16/94) on the MOST network.

When activating a Volvo On Call service the phone module (PHM) transmits the information to the

infotainment control module (ICM). The infotainment control module (ICM) transmits on to the driver information module (DIM) (5/1) that displays a text message that a Volvo On Call service is activated and what status it has.

Each time a Volvo On Call service is started the present vehicle data is transmitted to Volvo On Call Service Center. The vehicle data contains information about:

- **Call type.** SOS or On Call service.
- **The time at which the message was transmitted.** The Phone module (PHM) receives information about time from the Aerial module (ATM) (16/110) (-2006) or the Multimedia module (MMM) (16/108) (2007-), via the MOST network.
- **The Vehicle VIN number.** Phone Module (PHM) receives information from the central electronic module (CEM) via the controller area network (CAN).
- **Alarm status** (deactivated, activated, deployed). The phone module (PHM) receives information about the status of the alarm from the central electronic module (CEM) via the controller area network (CAN).
- **Position of the ignition key.** The Phone module (PHM) receives information about the position of the ignition key (in/out, position I, II or III) from the central electronic module (CEM) via the controller area network (CAN).
- **The vehicle's position.** The Phone module (PHM) receives the position of the vehicle, from the Aerial module (ATM) (-2006) or the Multimedia module (MMM) (2007-), via the MOST network.
- **Voltage source.** What voltage source is used by the phone module (PHM). Main or back-up battery.
- **Engine running or not.** The phone module (PHM) receives a signal from the central electronic module (CEM) via the controller area network (CAN).
- **Fuel volume.** The phone module (PHM) receives the information about the remaining fuel volume from the central electronic module (CEM) via the controller area network (CAN).
- **Status of main battery.** The phone module (PHM) receives information about the voltage over the main battery from the central electronic module (CEM) via the controller area network (CAN).
- **Ambient and internal temperature.** The phone module (PHM) receive information about the ambient temperature from the central electronic control module (CEM) and the internal temperature from the climate control module (CCM) (3/112) via the controller area network (CAN).
- **Locked/unlocked.** The phone module (PHM) receives information about whether the vehicle is locked from the inside or from the outside, from the Central electronic module (CEM) via the controller area network (CAN).
- **Front side window open/closed.** The phone module (PHM) receives information about the status of the front side windows from the driver door module (DDM) (3/126) and the passenger door module (PDM) (3/127) via the controller area network (CAN).
- **SRS activated or not.** The phone module (PHM) receives information about whether the vehicle has been in a collision and the SRS system has been activated. The information is received from the Supplemental restraint system module (SRS) (4/9), both via the controller area network (CAN) and the collision cable. The collision cable runs from the Supplemental restraint system module (SRS) to the phone module (PHM) and the central electronic module (CEM). The collision cable is a backup solution in the event of the controller area network (CAN) communication disappearing.

Safety

An SOS service can be started in two ways:

- automatically, in the event of a collision when a component in the SRS system has been activated
- manually, by the customer pressing the SOS button or selecting the service from the phone menu.

In a collision where an SRS component is activated the signal is transmitted from the supplemental restraint system module (SRS) to the phone module (PHM). The phone module (PHM) transmits the vehicle data to Volvo On Call Service Center which connects a call to the vehicle. The call is made in order to establish what action is necessary, for example, whether an ambulance or recovery vehicle is required.

When a Volvo On Call service has been activated the reserve battery is used if there is not sufficient voltage in the main battery.

Service

The Volvo On Call Service Center gives the customer access to various services, such as:

- road assistance
- remote unlocking of the vehicle
- theft message
- localization of stolen vehicle
- remote start of parking heater
- remote-controlled immobilization
- unpermitted movement.

The services that the customer can access vary between different markets.

Road assistance

Help in case of, e. g., a flat tire or if you run out of fuel.

Remote unlocking of the vehicle

Unlocking of the vehicle if the driver happens to lock the keys in the vehicle. Remote unlocking of the vehicle occurs after the owner has contacted the Volvo On Call Service Center, identified themselves using a password and given the required service. The owner and Volvo On Call Service Center then decide at what time the vehicle should be unlocked. The Service center can then transmit a command to the phone module (PHM) that the vehicle must be unlocked.

The central electronic module (CEM) will then transmit a signal via the CAN network to the phone module (PHM) when the handle on the tailgate is closed. If the signal from the central electronic module (CEM) is within the time interval agreed by the customer and the Volvo On Call Service Center, the phone module (PHM) then transmits a request to unlock the car to the central electronic module (CEM) via the CAN network. Then Central electronic module (CEM) sends a signal to driver door module (DDM), passenger door module (PDM) and Rear electronic module (REM) which unlocks all doors. The phone module (PHM) then transmits an acknowledgement to the Volvo On Call Service Center that the car has been unlocked. When one of the

doors or tailgate is opened, the alarm is triggered. The alarm is then active until it is correctly deactivated.

Theft message

If the vehicle alarm is activated, for example by theft, information about the alarm status is transmitted from the central electronic module (CEM) to the phone module (PHM) via controller area network (CAN). If the alarm is active for more than 15 seconds the phone module (PHM) transmits the vehicle data to the Volvo On Call Service Center, which contacts the owner and informs what has happened. In the first instance Volvo On Call Service Center calls the vehicle, if the person answering cannot give the password the owner is called on other numbers that the owner has supplied to the Service center.

Localization of stolen vehicle

If the vehicle has been stolen the owner can request that the service center localizes the vehicle. The Service center transmits a request to the phone module (PHM) to continuously send vehicle data. The interval of the vehicle data that is sent is determined by the Volvo On Call Service Center.

Remote start of parking heater

Applies from and incl. structure week 201020.

With remote start of the parking heater it is possible to set timers for the parking heater as well as start the parking heater directly via a computer with internet connection or via mobile telephone.

Remote-controlled immobilization

Applies for the English, Dutch, and Belgian market. A special version with stricter requirements is available for the Brazilian market. Applies from and incl. structure week 201020.

On certain markets there is a function for remote-controlled immobilization and mobilization. The purpose of the function is to nullify the vehicle's programmed keys in case the vehicle is stolen, for example. The vehicle can be immobilized and mobilized either using Volvo On Call service center or via diagnostic commands in VIDA (Volvo scan tool). For certain markets vehicles can only be mobilized by Volvo On Call service center.

If the vehicle is running when immobilization is requested, the vehicle is immobilized at the next start attempt. Central electronic module (CEM) can, in certain markets, request immobilization if the module detects that Phone module (PHM) does not answer to communication. The function remote-controlled immobilization is diagnosed by Central electronic module (CEM). Immobilization and mobilization of vehicles via diagnostic commands takes place via Phone module (PHM).

Unpermitted movement

Applies for the English, Dutch, and Belgian market from and incl. structure week 201020.

When the vehicle is to be used, the drivers must identify themselves by entering a six-digit code. If the vehicle is driven off without entering a code this is counted as an unpermitted movement

The function is activated automatically one minute after the vehicle's engine has been turned off, regardless of if the vehicle is locked or not. When the function is active the vehicle is monitored to detect unpermitted movement. Unpermitted movement is either that the vehicle is moved with the engine off (towing or loading and transport on trailer, etc.) or that the vehicle is driven off with the engine on without the right code having been entered. If the wrong code is entered three times in a row this will also be counted as an unpermitted movement, even if no movement has taken place. The limit value for unpermitted movement varies depending on current sensor status and on which market the vehicle has been sold. The limit value is normally between 100 - 400 metres. The function uses angle sensor, odometer, and GPS to detect unpermitted movement.

If the function detects unpermitted movement of the vehicle, a notice is sent from the vehicle to Volvo's On Call Service Center. The vehicle's owner and authorities or police can then be informed that the vehicle has been stolen. The Phone module (PHM) then continuously sends information to Volvo's On Call Service Center about the vehicle's whereabouts in the form of GPS coordinates. This information can be used to make it easier for the driver and authorities or police to locate and recover the vehicle.

Mobile applications (only applies to MY 2012)

Mobile applications use Volvo On Call to communicate with the vehicle.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 132: Identifying Phone Module (Phm)
Courtesy of VOLVO CARS CORPORATION

Two versions of the phone module (PHM) are available, with or without Volvo On Call functionality (market dependent).

The main function of the phone module (PHM) is to manage functions for:

- voice calls
- automatic connection to service centers in the event of a collision or alarm (Volvo On Call)
- connection to a service center for other services when the SOS or ON CALL button (Volvo On Call) has been pressed.

The control module is located behind the center console.

Phone module (PHM) with Volvo On Call functionality cannot be retro fitted.

The phone module (PHM) communicates partly with directly connected components and partly with other control modules via the CAN and MOST networks. All diagnostic communication between VIDA and the phone module (PHM) occurs via the CAN network.

The phone module (PHM) does not have a separate keypad but uses menu handling of the keypad and display for the infotainment control module (ICM).

The control module checks activations and input and output signals using an integrated diagnostic system A diagnostic trouble code (DTC) is stored if the control module detects an error. In certain cases the control module replaces the faulty signal with a substitute value.

For phone modules (PHM) with Volvo On Call functionality the driver will be alerted by a message in the driver information module (DIM) when a diagnostic trouble code (DTC) is stored.

Any diagnostic trouble codes (DTCs) are stored in the control module memory. This information can be read off using VIDA via the data link connector (DLC) in the vehicle.

If the phone module (PHM) is not supplied with voltage there will be no communication with the MOST network and the system will shut off.

The phone module (PHM) has a SIM card reader for the customer private telephone subscription. For phone modules (PHM) with the Volvo On Call function there is also an internally mounted SIM card. This subscription is only connected to the service center which supplies Volvo On Call services.

The following applies to phones with Volvo On Call

A started Volvo On Call service will always have higher priority than a call via the customer's private telephone subscription. A normal phone call will either not be possible or will be interrupted while a Volvo On Call service is active.

The phone module (PHM) with Volvo On Call function has an integrated spare battery. The reserve battery must ensure that the control module is supplied with voltage when a Volvo On Call service is activated if normal battery voltage is not available. This means that the main battery should be disconnected as short time as possible to save the spare battery. The residual capacity of the spare battery is calculated by the control module. When the battery is replaced the level of the capacity must be restored to full value. This is carried out using VIDA (Volvo scan tool). When the calculated capacity has fallen to 30% of full capacity a diagnostic trouble code is stored.

The phone module (PHM) with Volvo On Call function has a reserve microphone and reserve loudspeaker. The loudspeaker is located internally in the control module and the microphone is located by the switches for Volvo On Call. The reserve microphone and the reserve loudspeaker are only used when a Volvo On Call service is activated and the normal loudspeaker and handsfree microphone are not available.

The phone module (PHM) with the Volvo On Call function has an integrated reserve antenna. This is located

internally in the control module. The reserve antenna is only used when a Volvo On Call service is activated and when the normal antenna does not function.

SIGNALS

The table below summarizes the input signals and output signals to and from the phone module (PHM). The signal type is divided into directly connected signals, MOST and CAN communication. The illustration below reproduces the same information and Volvo component designations.

Input signals	Output signals
Directly connected: • SIM card holder (16/94) • Antenna signal, phone (16/64) • Microphone, handset (16/62) (model year-dependent) • Switch for Volvo On Call including reserve microphone (only for Volvo On Call) (3/267) • Collision signal from supplemental restraint system (SRS) (4/9) (only applies to phone modules (PHM) with Volvo On Call)	**Directly connected:** (power supply unless otherwise stated) • Antenna signal, phone (16/64) • Speaker, handset (16/62) (model year-dependent)
Via Controller Area Network (CAN) communication: • Central electronic module (CEM) (4/56) • Supplemental Restraint System Module (SRS) (4/9) • Driver door module (DDM) (3/126) • Passenger door module (PDM) (3/127) • Brake Control Module (BCM) (4/16) • Driver information module (DIM) (5/1)	**Via Controller Area Network (CAN) communication:** • Central electronic module (CEM) (4/56) • Driver information module (DIM) (5/1)
Via MOST communication: • Infotainment control module (ICM) (16/94) • Audio module (AUD) (microphone sound with handsfree) (16/105) • Antenna module (ATM) (16/110) (vehicle position, only applies to -2006 for phone modules (PHM) with Volvo On Call) • Multimedia module (MMM) (16/108) (vehicle position, via GPS, only applies to 2007- for phone modules (PHM) with Volvo On Call) • The Global positioning system module (GPS) (16/139) (only applies to 2007-, for vehicle's	**Via MOST communication:** • Infotainment control module (ICM) (16/94) • Audio module (AUD) (loudspeaker sound for handsfree) (16/105)

PHONE MODULE (PHM) (2003-2005)

DESIGN

CARPHONE ANTENNA

Fig. 134: Identifying Carphone Antenna
Courtesy of VOLVO CARS CORPORATION

The carphone antenna is directly connected to the phone module (PHM).

The carphone antenna is in the front windshield in front of the rear view mirror.

There are diagnostics for the antenna.

HANDSET

Fig. 135: Identifying Handset
Courtesy of VOLVO CARS CORPORATION

The handset is directly connected to the phone module (PHM). The handset is in the center console.

The phone module (PHM) determines whether to connect the call using hands free or the handset, depending on the signal from the cradle. When the handset is in the cradle, all voice calls are hands free. The handset is activated when it is removed from the cradle. The cradle signal to the phone module (PHM) is controlled by a solenoid switch in the handset. The switch is closed by a magnet in the cradle. When the handset is in the cradle, the cradle signal to the phone module (PHM) is 0 V. The signal is 5 V when the handset is in use.

There are diagnostics for the handset.

SIM CARD HOLDER

Fig. 136: Locating Sim Card Holder
Courtesy of VOLVO CARS CORPORATION

The holder for the customer's private SIM card is in the keypad for the infotainment control module (ICM). The SIM card holder is connected to the phone module (PHM) via serially connected wiring.

There are diagnostics for the SIM card holder.

DIAGNOSTIC FUNCTIONS

GENERAL

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. A fault which is detected in the most recent operating cycle is defined as permanent. Other faults are defined as intermittent.

The control module can store up to ten diagnostic trouble codes (DTCs).

Should a fault disappear for any reason after being permanently stored in the control module as a diagnostic trouble code (DTC), the information remains stored in the control module.

If a fault is no longer permanent, the diagnostic trouble code (DTC) remains as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N.

READING OFF EXTENDED FAULT-TRACING INFORMATION

This function can be used to read parameters, status identifiers and counters stored at the same time as a diagnostic trouble code (DTC). These are called frozen values.

For further information, see **DESCRIPTION OF FROZEN VALUES, PHONE MODULE (PHM)** .

READING OFF THE PARAMETERS

Using this function, the status or value of parameters can be read off. The presentation of the status or value can be obtained graphically or digitally. For further information about the different parameters, see **DESCRIPTION OF PARAMETERS** .

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the phone module (PHM). When ordering software, the hardware and the software in the car is compared to the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

The control module is positioned behind the center console.

After replacing the control module, check the unique serial number of the infotainment control module (ICM). If the serial number is not correct, the installed control module is not functioning.

If problems arise after downloading the software and the control module does not function, try switching the ignition off and then on again.

When totally reloading the software in the car, select CAN network.

FUNCTION

CARPHONE

Fig. 137: Identifying Carphone Network
Courtesy of VOLVO CARS CORPORATION

The phone module (PHM) (16/60) for the XC90 does not have its own keypad to control the menus. It uses the keypad on the infotainment control module (ICM) (16/1) panel.

When controlling the menus via the steering wheel buttons (3/131), the information is transmitted from the steering wheel module (SWM) (3/130) to the infotainment control module (ICM) via the CAN network. The information is then sent on to the phone module (PHM) via the MOST network.

The menu is displayed for the user in the infotainment control module's (ICM) display. The information is transmitted from the phone module (PHM) to the infotainment control module (ICM) via the MOST network.

When the phone module (PHM) is started, a request is transmitted to the infotainment control module (ICM) to use the display when there are incoming calls or when the carphone is in use.

Telephone calls can be made either hands free or using the handset. The phone module (PHM) for the XC90 does not have its own microphone or loudspeaker for hands free.

The microphone and loudspeaker for the Audio module (AUD) (16/105) are used instead for hands free calls. The phone module (PHM) transmits a request to the infotainment control module (ICM) to access the audio module (AUD) loudspeaker and microphone.

Communication between the phone module (PHM), infotainment control module (ICM) and audio module (AUD) is via the MOST network.

SYSTEM OVERVIEW

PHONE MODULE (PHM)

Fig. 138: Viewing Phone Module (PHM)
Courtesy of VOLVO CARS CORPORATION

The main task of the phone module (PHM) is to manage voice calls.

The control module is behind the center console.

The phone module (PHM) communicates with components which are directly connected and with other control modules and components via serial communication. The phone module (PHM) uses the MOST network to communicate with other control modules. Diagnostic communication and software downloads are via the Controller area network (CAN).

The phone module (PHM) does not have its own keypad. The keypad and display for the infotainment control module (ICM) are used to manage menus.

The control module checks activations and input and output signals via an integrated diagnostic system. A

diagnostic trouble code (DTC) is stored if the control module detects an error. In certain cases the control module replaces the faulty signal with a substitute value.

Any diagnostic trouble codes (DTCs) are stored in the control module memory. This information can be read off using VIDA via the data link connector (DLC) in the car.

If the phone module (PHM) is not powered, there will be no MOST network communication. The Infotainment Control Module (ICM) will then shut down all functionality on the MOST network.

SIGNALS

The following table summarizes the input signals to and output signals from the phone module (PHM). The signal types are divided into directly connected signals and MOST communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: • Antenna signal, carphone (16/64) • Microphone, handset (16/62) • SIM card holder (16/1).	**Directly connected:** (power supply unless otherwise stated) • Antenna signal, carphone (16/64) • Loudspeaker, handset (16/62).
Via MOST communication: • Infotainment Control Module (ICM) (16/1) • Audio control module (AUD) (16/105) microphone sound during hands free usage.	**Via MOST communication:** • Infotainment Control Module (ICM) (16/1) • Audio control module (AUD) (16/105) loudspeaker sound during hands free usage.

POWER SEAT MODULE (2003-2004)

DESIGN

CONTROL PANEL

Fig. 140: Identifying Power Seat Control Module
Courtesy of VOLVO CARS CORPORATION

There are two different types of control panels. In cars with power seats without memory, the control panel is directly connected to the motors and does not have a power seat module.

In cars with power seats and memory, the control panel is directly connected to the power seat module. An easy way of differentiating between power seats with memory (power seat module) and power seats without memory is to look at the control panel. Seats without memory do not have memory buttons 1- 3 or a programming button.

This information refers to seats with memory (power seat module) unless otherwise stated.

The control panel is connected to the power seat module via wiring that is integrated in the control panel. The entire control panel must be replaced if there is a fault with the wiring or the panel.

The panel is used to transmit input signals to the control module from the user:

- Runs each of the four motors in the direction required
- Memory buttons. Input signal indicating the position of the buttons (Memory 1, 2 and 3 and the programming button)
- Ground
- To detect that a control panel is connected to the control module.

If there is no supply to the control panel, because of an open-circuit in the cable for example, the control module will not register any input signals from the control panel. If a cable breaks only that function will fail. For

example Memory 1 cannot be programmed but the other memories are functioning.

The wiring cannot be replaced separately. The entire control panel must be replaced if there is a fault.

The control panel can be diagnosed.

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the power seat module. When ordering software, the hardware and the software in the car is compared to the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database does not correspond, the database is updated with the configuration of the car. New software is downloaded after the update is complete.

A control module may already have software installed which will result in incorrect information being updated on Volvo's Central Database. To avoid this, tick the box in the VIDA software manager indicating the software has been replaced when the control module has been replaced.

A number of customer parameters can be programmed into the power seat module. These customer parameters are stored in the control module but not in the Volvo central database. This means that the customer parameters must be reprogrammed when the hardware is replaced and when downloading software.

The power seat module calculates the current required by the motors. A current limit can be set to protect the wiring from high currents.

- There is a parameter which detects when the seat has reached its limit position, in other words blocked motor. (Programmable)
- There is a parameter for detecting short-circuits (Can be read off).

The value of the current for a blocked motor can be set using the diagnostic tool. When programming, the value of the blocked motor must be less than the value for a short-circuit. If this is not the case, the control module will indicate a short-circuit in the cable when the seat is run to its limit position.

The motor stops when the current exceeds the value for a blocked motor and the control module registers no pulses from the Hall sensor. The level of current for a blocked motor can be set between 9 and 20 Amperes.

It is possible to reprogram the function so that the seat is automatically set by remote control. With this function activated the seat can be set using the remote control. This function is removed if it is deactivated.

FUNCTION

SEAT PROGRAMMING

Fig. 141: Identifying Seat Programming Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

There are four buttons for programming seat positions. There are three memory buttons, 1, 2 and 3 and a programming button, MEM.

To program a new seat position, move the seat to the desired position and press MEM and one of the memory buttons at the same time.

To move the seat to a programmed position press and hold down the desired memory button. The button must be kept depressed for the seat to move. The seat stops if the button is released.

The seat stops moving when the position of the seat matches the position programmed into the memory. If another button is pressed the seat will stop moving. The seat will not move if no position is programmed.

If the car was built in structure week 9950 or later, the car has door mirrors with memories. When the desired memory button is pressed, the mirrors and seat are set to the desired positions. Data is sent from the power seat module (4/52) to the passenger door module (3/126) (3/127) to set the door mirrors to the programmed position. The memory positions of the door mirrors are stored in the driver's door module (DDM) (3/126) and passenger door module (PDM) (3/127). When setting a new mirror position, this is stored in each control module. The position of the driver's door mirror is stored in the driver door module (DDM). The position of the passenger door mirror is stored in the passenger door module (PDM).

When the seat is run, a maximum of two motors are activated at the same time. If all motors need to operate to reach the programmed position, there is an order of priority. Motor 1 (front-rear adjustment) and Motor 2 (backrest adjustment) operate first.

Each seat motor has a Hall sensor which detects the current seat position. When one of the stepper motors for the seat is run, the control module counts the number of pulses from the Hall sensor. The Hall sensor counts the number of revolutions made by the motor by detecting a magnet on the motor shaft. This creates a pulse for each revolution of the motor.

When a seat position is stored, information about the number of pulses recorded from each motor is stored in a memory, allowing the position of the seat to be saved.

When one of the memory buttons is pressed in, the control module calculates which motors need to be run and

in which direction to obtain the desired position.

MANEUVERING SEATS WITH MEMORY

Fig. 142: Identifying Seat Motors
Courtesy of VOLVO CARS CORPORATION

On a power seat, the backrest can be adjusted, the seat height can be altered and the seat can be moved forwards or backwards. There are four motors for moving the seat. The control buttons are on the outside of the seat and are in the shape of a small seat and a small backrest. There are two control buttons on each panel. The buttons are spring-loaded, so they must be held pressed in for the seat to move.

The seat can be maneuvered:

- Within a period of 9 minutes and 40 seconds of the door being opened
- Within 40 seconds of the door being closed
- With the key in the radio position
- With the ignition on.

REMOTE OPERATION OF SEATS

Fig. 143: Identifying Input / Output Signals For Remote Operation Of Seats
Courtesy of VOLVO CARS CORPORATION

There are three memories in the power seat module (PSM) which store the seat positions for a maximum of 3 remote controls. There are also three further memory positions which can be stored from the control panel. The seat can store a total of six different memory positions.

Cars with power seats with memory have a personal setting function. Using this function, the positions of the mirrors and seat can be stored individually for each remote control (a maximum of three remote controls, i. e. remote memory positions 1, 2 and 3).

The customer parameters in the power seat module (4/52) determine whether the remote memory for the seat is activated or not.

From model year 2003 inclusive the remote control memory for the mirrors can also be switched off. This is done using a customer parameter in the driver's door module (DDM) (3/126) and passenger door module (PDM) (3/127). "Programming of the remote control settings" for seats and mirrors is carried out via VIDA vehicle communication.

The signal from the remote control is transmitted to the upper control module (UEM) (4/70) when the car is locked or unlocked. The upper electronic module (UEM) also identifies which remote control is being used. The central electronic module (CEM) (4/56) receives this information from the upper electronic module (UEM). The central electronic module (CEM) identifies and stores the remote control which is being used and determines the data to be sent to the power seat module (PSM) (4/52), driver door module (DDM) (3/126) and passenger door module (PDM) (3/127). This is done when the door is opened.

For model year 2003 the central electronic module (CEM) transmits information about which remote control locked the car.

From model year 2003 inclusive , the central electronic module (CEM) transmits information about which remote control locked the car and which unlocked the car.

If the position of the seat is changed, the power seat module (PSM) (4/52) stores the new position before reverting to sleep mode.

Remote memory positions are stored in the power seat module (PSM) in the following cases:

- 10 minutes after the door has been opened
- 1 minute after the door has been closed
- With the ignition off
- When the key is removed from the ignition switch
- When a new remote control is activated.

The remote memory positions for the door mirrors are stored for the driver door module (DDM) and passenger door module (PDM) in the following cases:

- When the key is removed from the ignition switch
- When a new remote control is activated.

When the car is unlocked, the power seat module (PSM) uses the information about which remote control unlocked the car. This is so that the correct remote memory position can be selected (i. e. the seat position last set by the driver for this remote control). When the door is opened the seat starts to move to the programmed remote memory position. The seat can be stopped by pressing one of the buttons on the control panel.

If the car is opened with a key, the memory settings for the seat are not affected. Remote operation of the seat is not possible if the key is in the ignition switch.

On model year 1999-2002 cars, the system may exhibit unwanted properties. Only information about which remote control unlocked the car is transmitted, a new memory position is not stored if the car was unlocked before this. This is because when a car door is opened and the power seat module (PSM) switches into active mode, the module is unable to identify which remote control is being used.

In addition, when a door is open, it takes 10 minutes before the power seat module (PSM) switches to sleep mode. If this occurs, and the customer then attempts to set a new seat position, the information about which remote control opened the door will have been lost and a new memory position will not be stored.

MANEUVERING SEATS WITHOUT MEMORY

Fig. 144: Identifying Seats Control Panel
Courtesy of VOLVO CARS CORPORATION

Power seats without memory do not have memory management buttons. The seat motors can only be operated directly via the control panel. This type of seat does not have a power seat module (PSM). The seat motors are directly connected to the control panel.

POWER SEAT MODULE DIAGNOSTIC FUNCTIONS

GENERAL

The control module has a built-in diagnostic system, the Volvo on-board diagnostic (OBD) system, which continuously monitors itself and its input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

If the control module detects a fault it will store a diagnostic trouble code (DTC). A fault which is detected in the latest driving cycle is defined as permanent. Other detected faults are defined as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be erased using this function.

Erasing diagnostic trouble codes (DTCs) can only be carried out when all diagnostic trouble codes (DTCs) have been read at least once.

READING OFF CONTROL MODULE IDENTIFICATION

VIDA identifies the control modules by reading off a number of codes from control module memory.

The codes contain information about control module:

- P/N hardware (control module without software)
- serial number hardware (control module without software)
- P/N software

- P/N diagnostic software

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 145: Identifying Power Seat Control Module
Courtesy of VOLVO CARS CORPORATION

The task of the power seat module is to manage the following functions:

- Seat maneuvering
- Storage of memory positions (seat positions only).

The control module is under the seat on the driver's side. The seat must be removed in order to replace the control module.

The power seat module is directly connected to components and to other control modules via CAN communication.

The control module checks activations and input and output signals through an integrated diagnostic system A diagnostic trouble code (DTC) is stored in certain cases if the control module detects a fault.

Diagnostic trouble codes (DTC) are stored in the control module memory. The data can be read off using the diagnostic tool.

A simple way to check that the power seat module (4/52) is supplied with power and grounded is to move the seat.

If the voltage is below 8.5 V or above 16.0 V the power seat module will not function. If the voltage increases to 9.0 V or falls to 15.5 V the control module will function again.

SIGNALS

The table below summarizes input and output signals to and from the power seat module (4/52). The signal

types are divided into directly connected signals, serial communication and Control area network (CAN) communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: Control panel (3/26) with: • Control buttons (eight input signals, two buttons) • Memory button 1, 2 and 3 • Programming button (MEM). Hall sensors (four integrated in the seat motor) Control circuit connected to the control panel	**Directly connected:** (power supply unless otherwise stated) Seat motors (6/16-19) (four) Voltage supply signal EXT. X
Via Control Area Network (CAN): Central electronic module (4/56) Upper electronic module (4/70)	**Via Control Area Network (CAN):** Passenger door module (3/126) Driver's door module (3/127)

Fig. 146: Identifying Volvo Component Designations

POWER SEAT MODULE (PSM) (2005-2012)

DESIGN

CONTROL PANEL

Fig. 147: Identifying Power Seat Control Module
Courtesy of VOLVO CARS CORPORATION

There are two different types of control panels. In vehicles with power seats without memory, the control panel is directly connected to the motors and does not have a power seat module (PSM).

In vehicles with power seats with memory, the control panel is directly connected to the power seat module (PSM). An easy way of differentiating between power seats with memory and power seats without memory is to look at the control panel. Seats without memory do not have memory buttons 1- 3 or a programming button.

This information refers to seats with memory (with a power seat module (PSM)) unless otherwise stated.

The control panel is connected to the control module via wiring that is integrated in the control panel. The entire control panel must be replaced if there is a fault with the wiring or the panel.

The panel is used to transmit input signals to the control module from the user:

- Runs each of the four motors in the direction required
- Memory buttons. Input signal indicating the position of the buttons (Memory 1, 2 and 3 and the programming button)
- Ground
- To detect that a control panel is connected to the control module.

If there is no supply to the control panel, because of an open-circuit in the cable for example, the control module will not register any input signals from the control panel. If a cable breaks only that function will fail. For example Memory 1 cannot be programmed but the other memories are functioning.

The wiring cannot be replaced separately. The entire control panel must be replaced if there is a fault.

There are diagnostics for the control panel.

DIAGNOSTIC FUNCTIONS

GENERAL

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. A fault which is detected in the most recent operating cycle is defined as permanent. Other faults which are detected are defined as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory. The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N.

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the engine power seat module (PSM). When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and the Volvo central database does not correspond, the database is updated with the configuration of the car. New software is downloaded after the update is complete.

A control module may already have software installed which will result in incorrect information being updated in the Volvo Central Database. To avoid this, tick the box in the VIDA software manager indicating the software has been replaced when the control module has been replaced.

A number of customer parameters can be programmed into the power seat module (PSM). These customer parameters are stored in the control module but not in the Volvo central database. This means that the customer parameters must be reprogrammed when the hardware is replaced and when downloading software.

The power seat module (PSM) calculates the current required by the motors. A current limit can be set to protect the wiring from high currents.

- There is a parameter which detects when the seat has reached its limit position, in other words blocked motor. (Programmable)
- There is a parameter for detecting short-circuits. (Can be read off).

The value of the current for a blocked motor can be programmed using VIDA (Volvo scan tool). When programming, the value of the blocked motor must be less than the value for a short-circuit. If this is not the case, the control module will indicate a short-circuit in the cable when the seat is run to its limit position.

The motor stops when the current exceeds the value for a blocked motor and the control module registers no pulses from the Hall sensor. The level of current for a blocked motor can be set between 9 and 20 Amperes.

It is possible to reprogram the function so that the seat is automatically set by remote control. With this function activated the seat can be set using the remote control. This function is not available if it is deactivated.

FUNCTION

SEAT PROGRAMMING

Fig. 148: Identifying Seat Programming Communication Links
Courtesy of VOLVO CARS CORPORATION

There are four buttons for programming seat positions. There are three memory buttons, 1, 2 and 3 and a programming button, MEM.

To program a new seat position, move the seat to the desired position and press MEM and one of the memory buttons at the same time.

To move the seat to a programmed position press and hold down the desired memory button. The button must be kept depressed for the seat to move. The seat stops if the button is released.

The seat stops moving when the position of the seat matches the position programmed into the memory. If another button is pressed the seat will stop moving. The seat will not move if no position is programmed.

On vehicles with mirrors with memories, the desired positions for the mirrors and seat are set when the relevant memory button is pressed. Information is sent from the power seat module (PSM) (4/52) to the passenger door

module (PDM) (3/127) and driver door module (DDM) (3/126) to set the door mirrors to the programmed position. The memory position of the door mirrors are stored in the driver door module (DDM) and the passenger door module (PDM). When setting a new mirror position, this is stored in each control module. The position of the door mirror on the driver's side is stored in the driver door module (DDM). The position of the door mirror on the passenger side is stored in the passenger door module (PDM).

When the seat is run, a maximum of two motors are activated at the same time. If all motors need to operate to reach the programmed position, there is an order of priority. Motor 1 (front-rear adjustment) and Motor 2 (backrest adjustment) operate first.

Each seat motor has a Hall sensor which detects the present position of the seat. When one of the stepper motors for the seat is run, the control module counts the number of pulses from the Hall sensor. The Hall sensor counts the number of revolutions made by the motor by detecting a magnet on the motor shaft. This creates a pulse for each revolution of the motor.

When a seat position is stored, information about the number of pulses recorded from each motor is stored in a memory, allowing the position of the seat to be saved.

When one of the memory buttons is pressed in, the control module calculates which motors need to be run and in which direction to obtain the desired position.

MANEUVERING SEATS WITH MEMORY

Fig. 149: Locating Seat Memory And Control Components
Courtesy of VOLVO CARS CORPORATION

On a power seat, the backrest can be adjusted, the seat height can be altered and the seat can be moved forwards or backwards. There are four motors for moving the seat. The control buttons are on the outside of the seat and are in the shape of a small seat and a small backrest. There are two control buttons on each panel. The buttons are spring-loaded, so they must be held pressed in for the seat to move.

The seat can be maneuvered:

- Within a period of 9 minutes and 40 seconds of the door being opened
- Within 40 seconds of the door being closed

- With the key in the radio position
- With the ignition on.

REMOTE OPERATION OF SEATS

Fig. 150: Identifying Remote Operation Of Seats
Courtesy of VOLVO CARS CORPORATION

There are three memories in the power seat module (PSM) which store the seat positions for a maximum of 3 remote controls. There are also three further memory positions which can be stored from the control panel. The seat can store a total of six different memory positions.

Cars with power seats with memory have a personal setting function. Using this function, the positions of the mirrors and seat can be stored individually for each remote control (a maximum of three remote controls, i. e. remote memory positions 1, 2 and 3).

The customer parameters in the power seat module (PSM) (4/52) determine whether the remote memory for the seat is activated or not.

The remote control memory for the door mirrors can also be switched off. This is done using a customer parameter in the driver door module (DDM) (3/126) and passenger door module (PDM) (3/127). "Programming of the remote control settings" for seats and mirrors is carried out via VIDA vehicle communication.

The signal from the remote control is transmitted to the upper control module (UEM) (4/70) when the car is locked or unlocked. The upper electronic module (UEM) also identifies which remote control is being used. The central electronic module (CEM) (4/56) receives this information from the upper electronic module (UEM). The central electronic module (CEM) identifies and stores the remote control which is used. It also determines what

information must be sent to the power seat module (PSM), driver door module (DDM) and passenger door module (PDM). This is done when the door is opened.

The central electronic module (CEM) transmits information about which remote control locked the vehicle and which remote control unlocked the vehicle.

If the position of the seat is changed, this new position is stored after 5 seconds.

Remote memory positions are stored in the power seat module (PSM) in the following cases:

- 5 minutes after the door has been opened
- 1 minute after the door has been closed
- With the ignition off
- When the key is removed from the ignition switch
- When a new remote control is activated.

The remote memory positions for the door mirrors are stored for the driver door module (DDM) and passenger door module (PDM) in the following cases:

- When the key is removed from the ignition switch
- When a new remote control is activated.

When the car is unlocked, the power seat module (PSM) uses the information about which remote control unlocked the car. This is so that the correct remote memory position can be selected (i. e. the seat position last set by the driver for this remote control). When the door is opened the seat starts to move to the programmed remote memory position. The seat can be stopped by pressing one of the buttons on the control panel.

If the car is opened with a key, the memory settings for the seat are not affected. Remote operation of the seat is not possible if the key is in the ignition switch.

In addition, when a door is open, it takes 5 minutes before the power seat module (PSM) switches to sleep mode. If this occurs, and the customer then attempts to set a new seat position, the information about which remote control opened the door will have been lost and a new memory position will not be stored.

MANEUVERING SEATS WITHOUT MEMORY

Fig. 151: Identifying Seats Control Panel
Courtesy of VOLVO CARS CORPORATION

Power seats without memory do not have memory management buttons. The seat motors can only be operated directly via the control panel. This type of seat does not have a power seat module (PSM). The seat motors are directly connected to the control panel.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 152: Identifying Power Seat Control Module
Courtesy of VOLVO CARS CORPORATION

The primary task of the power seat module (PSM) is to manage the functions for:

- seat operation
- storage of memory positions (seat positions only).

The control module is under the seat on the driver's side. The seat must be removed in order to replace the control module.

The power seat module (PSM) communicates with directly connected components and with other control

modules via CAN communication.

The control module checks activations and input and output signals via an integrated diagnostic system. A diagnostic trouble code (DTC) is stored in certain cases if the control module detects a fault.

Any diagnostic trouble codes (DTCs) are stored in the control module memory. The data can be read off using VIDA (Volvo scan tool).

A simple way to check that the power seat module is supplied with power and grounded is to move the seat.

If the voltage is below 8.5 V or above 16.0 V, the power seat module (PSM) will not function. If the voltage increases to above 9.0 V or falls below 15.5 V, the control module will function again.

SIGNALS

The table below summarizes input and output signals to and from the power seat module (PSM) (4/52). The signal types are divided into directly connected signals, serial communication and controller area network (CAN) communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals

Directly connected:
• Control panel (3/26) with:
  • Control buttons (eight input signals, two buttons)
  • Memory button 1, 2 and 3
  • Programming button (MEM).
• Hall sensors (four integrated into the seat motor)
• Control circuit connected to the control panel.
	Directly connected:
	• Seat motors (6/16-19) (four units).

Via Controller Area Network (CAN) communication: • Central electronic module (CEM) (4/56) • Upper electronic module (UEM) (4/70).	**Via Controller Area Network (CAN) communication:** • Driver door module (DDM) (3/126) • Passenger door module (PDM) (3/127).

Fig. 153: Identifying Volvo Component Designations
Courtesy of VOLVO CARS CORPORATION

REAR ELECTRONIC MODULE (REM) (2003-2004)

DESIGN

INCLINATION SENSOR MODULE (ISM)

Fig. 154: Identifying Inclination Sensor Module
Courtesy of VOLVO CARS CORPORATION

The inclination sensor module (ISM) is on the left-hand side of the rear relay box.

The inclination sensor module (ISM) is powered from the rear electronic module (REM), which both activates and deactivates it. Information is transferred from the inclination sensor module (ISM) to the rear electronic

module (REM) using serial communication.

The inclination sensor module (ISM) detects when the angle of the car changes. If the angle changes when the car is alarmed, a signal is transmitted to the rear electronic module (REM) which sends this data out on the controller area network (CAN) to activate the alarm.

There are diagnostics for the Inclination Sensor Module (ISM).

HEADLAMP RANGE ADJUSTMENT POSITION SENSORS (BI-XENON)

Fig. 155: Headlamp Range Adjustment Position Sensors (Bi-Xenon)
Courtesy of VOLVO CARS CORPORATION

Cars with Bi-Xenon lamps have a position sensor so that the headlamps can automatically adjust beam length. The vertical adjustment accounts for load and road conditions to reduce the risk of dazzle.

The position sensor is beside the rear axle and is connected to the left-hand rear control arm by a linkage system. This linkage system affects the sensor, allowing the angle of the car to be gauged.

The position sensor is directly connected to the rear electronic module (REM) via three inputs. Two are used for the power supply and ground connection for the sensor. One input is used for signals about the angle of the car. The signals are received by the rear electronic module (REM) which sends them onwards via the Control area network (CAN) to the central electronic module (CEM) which controls the headlamp range adjustment function.

The position sensor can be calibrated using VIDA (Volvo scan tool). The calibration is saved in the rear electronic module (REM) and must be carried out again if the rear electronic module (REM) or position sensor is replaced.

There are diagnostics for the position sensor.

FUEL LEVEL

Fig. 156: Fuel Level Sensor
Courtesy of VOLVO CARS CORPORATION

The fuel level in the tank is measured by two sensors. The sensors are located on each side of the fuel tank. Cars with engine B5244S6 have only one sensor, on the pump side. The sensors are directly connected to the rear electronic module (REM).

There are different tables for different fuel tank sizes. These are stored in the rear electronic module (REM) and indicate which sensor values correspond to the remaining fuel in the tank. The rear electronic module (REM) determines which tank is in the car by reading a parameter.

The resistance of the sensor increases as the fuel volume in the tank decreases. The signals from the sensors are compared with the values in the fuel tank table to obtain a value for the remaining fuel volume. This data is displayed by the fuel gauge in the driver information module (DIM).

If the sensors are faulty, the fuel gauge will show 0.

There are diagnostics for the fuel level sensors.

FUEL LEVEL (BI-FUEL)

Fig. 157: Fuel Level Sensor (Bi-Fuel)
Courtesy of VOLVO CARS CORPORATION

CNG (Compressed Natural Gas)

The fuel level in the gasoline tank operates in the same way as for cars with B5244S6 engines, using a sensor in the tank. A combined pressure and temperature sensor is used to measure the fuel level in the gas tank. The sensor is on the left-hand side of the gas tank.

The sensor is directly connected to the rear electronic module (REM). The signals from the sensor are transmitted to the rear electronic module (REM) where they are calculated and sent to the driver information module (DIM) via the Control area network (CAN).

There are diagnostics for the fuel level sensor.

LPG (Liquefied Petroleum Gas)

The fuel level in the gasoline tank operates in the same way as for cars with B5244S6 engines, using a sensor in the tank.

A sensor, on the right-hand side of the tank, is used to measure the fuel level in the LPG tank. The sensor is directly connected to the rear electronic module (REM). The signals from the sensor are compared with a table stored in the rear electronic module (REM). Data about the remaining volume of fuel is transmitted via the Control area network (CAN) to the driver information module (DIM).

There are diagnostics for the fuel level sensor.

SHUT-OFF VALVE (BI-FUEL)

Fig. 158: Identifying Shut-Off Valve (Bi-Fuel)
Courtesy of VOLVO CARS CORPORATION

There are shut-off valves on the gas tanks to open and close the tank valves on bi-fuel cars.

These are positioned at the inlet/outlet on each gas tank. There is one for LPG and three for CNG.

The valves are controlled electro-magnetically and powered via a relay directly connected to the rear electronic module (REM). The rear electronic module (REM) activates the relay when a request for gas power is transmitted on the controller area network (CAN).

The valves close when the car is running on gasoline, when the ignition is switched off or in the event of a collision.

The valves can be opened via a diagnostic command by activating the relay for the gas valves. Activation is carried out in VIDA via the vehicle communication socket.

The valves can also be closed manually using an Allen key or opened by unscrewing the shut-off valve and replacing it with a special tool.

There are diagnostics for the shut-off valve relay.

REAR FOG LAMP

Fig. 159: Identifying Rear Fog Lamp And Back-Up Lamp
Courtesy of VOLVO CARS CORPORATION

The rear fog lamp are in the tail lamps. The fog lamps are operated via a button in the light switch module (LSM). An LED in the button lights when the fog lamps are activated. The rear fog lamp can only be activated when low beam is on (market dependent). The light switch transmits information to the central electronic module (CEM) using serial communication when the button for the rear fog lamp is pressed. The central electronic module (CEM) transmits the data via the Controller area network (CAN) to the rear electronic module (REM). The power supply for the lamps is via a directly connected relay on the rear electronic module (REM).

When reactivating key position II, the function is set to non-activated mode.

In order to detect bulb faults for the rear fog lamp, the rear electronic module (REM) detects the power consumption in the circuit using a directly connected shunt. If the power consumption falls below a certain limit, a fault is indicated and a text message is displayed in the driver information module (DIM).

There are diagnostics for the rear fog lamp relay.

BACK-UP LAMP

Fig. 160: Identifying Rear Fog Lamp And Back-Up Lamp
Courtesy of VOLVO CARS CORPORATION

There are two back-up (reversing) lamps. These are in the tail lamps. The back-up (reversing) lamp lights when back-up (reverse) gear is selected. The back-up (reversing) lamps are connected to the rear electronic module (REM) via a directly connected relay. The lamps are powered via the relay.

Cars with manual transmissions

Cars with manual transmissions have a back-up (reverse) switch on the transmission. The switch closes and transmits a directly connected signal to the central electronic module (CEM) when back-up (reverse) gear is selected.

There are diagnostics for the back-up (reversing) lamp relay.

Cars with automatic transmissions

In cars with automatic transmissions, a signal is transmitted from the transmission control module (TCM) on the Control area network (CAN) to the central electronic module (CEM) indicating that back-up (reverse) gear is selected.

There are diagnostics for the back-up (reversing) lamp relay.

BRAKE LIGHT

Fig. 161: Identifying Rear Fog Lamp And Back-Up Lamp
Courtesy of VOLVO CARS CORPORATION

The stop lamps are in the tail lamps. The lamps light when the stop lamp switch on the brake pedal is closed. The stop lamp switch is connected to the central electronic module (CEM). The signal from the stop lamp switch is sent on to the rear electronic module (REM) via a hardwired cable. The power supply for the lamps is via a directly connected relay on the rear electronic module (REM). In order for the stop lamps to work when the ignition is not on, there is no logic in the rear electronic module (REM) to activate the relay. The relay is activated directly by the signal from the stop lamp switch. The rear electronic module (REM) receives data via the controller area network (CAN) from the central electronic module (CEM) indicating that the stop lamp switch is activated.

In order to detect faults in the stop lamps, the rear electronic module (REM) detects the power consumption in the lamp circuit using a directly connected shunt. If the power consumption falls below a certain limit, a fault is indicated and a text message is displayed in the driver information module.

HIGH LEVEL STOP LAMP

Fig. 162: High Level Stop Lamp
Courtesy of VOLVO CARS CORPORATION

There is a high-mounted stop (brake) lamp on the inside of the rear windshield. This lamp lights during braking together with the standard stop lamps. The stop lamp is activated when the stop lamp switch on the brake pedal is closed.

The high mounted stop lamp is supplied with power directly from the rear electronic module (REM). The lamp consists of a number of LEDs.

There are diagnostics for the high level stop lamp.

REAR DEMIST

Fig. 163: Identifying Rear De-Mist
Courtesy of VOLVO CARS CORPORATION

There are heating loops in the glass for demisting and to prevent ice from forming. The loops heat up when they are supplied with power. The power supply is via a relay on the rear relay box. The relay is controlled by the rear electronic module (REM).

Rear demist is controlled using a switch on the right-hand side of the climate control module (CCM).

The engine must be running for the demister to work. Press the button again to switch off the function. Demisting is switched off automatically after the maximum time of 12 minutes.

The relay can be diagnosed by the rear electronic module (REM). The switch can be diagnosed via the climate control module (CCM).

CARGO COMPARTMENT LIGHTING

Fig. 164: Cargo Compartment Lighting
Courtesy of VOLVO CARS CORPORATION

There are lamps in the cargo compartment. In the XC90 there is a lamp in the trunk lid. The lamps light when the trunk lid is open. The cargo compartment lighting is powered directly from the rear electronic module (REM).

There are diagnostics for the cargo compartment lighting.

REAR 12 V SOCKET

Fig. 165: Identifying Rear 12 V Socket
Courtesy of VOLVO CARS CORPORATION

There is a 12V socket on the right-hand side of the cargo compartment. This socket can be used to power a number of accessories.

The socket is directly connected to the 30-supply via a fuse and a directly connected shunt on the rear electronic module (REM).

The rear electronic module (REM) measures the current through the shunt periodically and calculates an average value. This is compared with a limit value to determine if any power consuming component is connected.

This information is transmitted via the Control area network (CAN) to the driver information module (DIM) which displays a text message when a power consuming component is connected (applies only to factory installed 12V sockets).

PARKING ASSISTANCE (APPLIES ONLY TO THE XC90 2003-2004)

Fig. 166: Identifying Parking Assistance
Courtesy of VOLVO CARS CORPORATION

There is a back-up (reversing) warning system to assist reversing maneuvers. The back-up (reversing) warning system consists of:

- four sensors in the rear bumper
- a parking assistance module (PAM) under the rear relay box.

The parking assistance module (PAM) communicates with the rear electronic module (REM) using serial communication. The signals transmitted contain information about status and diagnostics. The sensors are directly connected to the Parking Assistance Module (PAM). The sensors are also powered via the parking assistance module (PAM).

The back-up (reversing) warning system is activated via a switch on the lower section of the climate control module (CCM). When the system is active, an LED lights in the switch and a text message is displayed in the infotainment control module (ICM)

The sensors detect objects within 1.5 meters and if reverse gear is engaged then a beeping tone can be heard from the rear loudspeakers. The tone intensifies when the car draws closer to the object. At approx. 30 cm the tone becomes continuous.

In the event of a fault in the parking assistance module (PAM) or sensors, the general warning lamp in the driver information module (DIM) lights and a text message is displayed.

There are diagnostics for the back-up (reversing) warning system.

DIAGNOSTIC FUNCTIONS

DIAGNOSTIC FUNCTIONS

GENERAL

The rear electronic module (REM) has a built-in diagnostic system, the Volvo on-board diagnostic (OBD) system, which continuously monitors itself and the input and output signals.

DIAGNOSTIC TROUBLE CODES (DTC)

A diagnostic trouble code (DTC) is stored if the rear electronic module (REM) detects a fault. This control module can store up to 6 diagnostic trouble codes (DTCs), the 3 first and the 3 latest.

Should a fault disappear for any reason after being permanently stored in the control module as a diagnostic trouble code (DTC), the information remains stored in the memory.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function. The on-board diagnostic (OBD) system can identify 58 different faults in the rear electronic module (REM) in the form of diagnostic trouble codes (DTCs).

This function can also be used to read off whether the fault is still present (permanent) or whether it has now ceased (intermittent) after the diagnostic trouble code (DTC) has been stored.

Diagnostic trouble codes (DTC) can only be erased once all the diagnostic trouble codes (DTC) have been read off at least once.

READING OFF INPUT AND OUTPUT SIGNALS

This function can be used to continuously read off the values and status of the rear electronic module (REM) input and output signals.

The following parameters can be read off:

- status of the locking relay and unlocking relay for the left rear door
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- status of the locking relay and unlocking relay for the right rear door
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- status of the relay for the rear folding head restraint
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- the status of the trunk lid pop-up relay (4 doors)
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- status of the locking relay and unlocking relay for the fuel tank filler cover
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- status of the rear fog lamp relay
  - Engaged = The gear selector lever is in the back-up (R) position

    - Disengaged = The gear selector lever is not in the back-up (R) position.
- status of the rear fog lamp relay, German version and trailer
    - Engaged = The gear selector lever is in the back-up (R) position
    - Disengaged = The gear selector lever is not in the back-up (R) position.
- status of the back-up lamp relay
    - Engaged = The gear selector lever is in the back-up (R) position
    - Disengaged = The gear selector lever is not in the back-up (R) position.
- status of the rear windshield heating relay
    - Engaged = The gear selector lever is in the back-up (R) position
    - Disengaged = The gear selector lever is not in the back-up (R) position.
- power supply from the rear electronic module (REM)
    - Engaged = The gear selector lever is in the back-up (R) position
    - Disengaged = The gear selector lever is not in the back-up (R) position.
- fuel level, left and right tank halves
    - Engaged = The gear selector lever is in the back-up (R) position
    - Disengaged = The gear selector lever is not in the back-up (R) position.
- input signal from the pressure sensor (CNG), Full (200bar): 4.5V Empty (0 bar): 0.5V)
    - Engaged = The gear selector lever is in the back-up (R) position
    - Disengaged = The gear selector lever is not in the back-up (R) position.
- input signal from the temperature sensor (CNG) (5V - 0.5V) (0°C~4.5V, 25°C~3.6V)
    - Engaged = The gear selector lever is in the back-up (R) position
    - Disengaged = The gear selector lever is not in the back-up (R) position.
- lamp fault. Indicates whether any bulb has blown. Parking lamp groups 1 and 2, cover the left and right rear parking lamps.
    - Engaged = The gear selector lever is in the back-up (R) position
    - Disengaged = The gear selector lever is not in the back-up (R) position.
- the power supply to the inclination sensor module (ISM) (low, high). High when the car is alarmed, otherwise low
    - Engaged = The gear selector lever is in the back-up (R) position
    - Disengaged = The gear selector lever is not in the back-up (R) position.
- Inclination sensor module (ISM), alarm status. Indicates whether the inclination sensor module (ISM) has deployed the alarm
    - Engaged = The gear selector lever is in the back-up (R) position
    - Disengaged = The gear selector lever is not in the back-up (R) position.
- Inclination sensor module (ISM), x/y status. Indicates whether the inclination sensor module (ISM) has deployed first in the X or Y axis
    - Engaged = The gear selector lever is in the back-up (R) position
    - Disengaged = The gear selector lever is not in the back-up (R) position.

- the status of the trunk lid handle, (pop up, no action) (4 doors)
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- current, bulb failure warning sensor group 1 (left rear parking lamps). The rear electronic module (REM) detects lamp faults when the current is below 0.6A (4 doors) / 0.45A (5 doors)
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- current, bulb failure warning sensor group 2 (right rear parking lamps). The rear electronic module (REM) detects lamp faults when the current is below 0.6A (4 doors) / 0.45A (5 doors)
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- current, lamp fault rear fog lamp. The rear electronic module (REM) detects lamp faults when the current is below 1.5A
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- Central electronic module (CEM) driver brake (off, on). Checks the input signal from the stop lamp driver from the central electronic module (CEM) to the rear electronic module (REM)
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- stop lamp check (lamp on, lamp off). Checks whether the rear electronic module (REM) transmits a signal to activate the stop lamp relay
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- current, lamp fault, stop lamp. The rear electronic module (REM) detects lamp faults when the current is below 3.0 A
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- status of the relay for the tailgate wiper. Controls starting and stopping the tailgate wiper (5 doors)
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- status of the relay for extended X-supply. Controls the power supply to the tailgate wiper (5 doors)
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- status relay 15I in the power supply
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- status relay gas tank valve (Bi-fuel)
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.

- status relay rear A/C (XC90)
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- cargo compartment lighting output signal (0W - 10W)
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- position sensor input signal for the headlamp beam height control (1.7V -3.2V)
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- calibration status of the position sensor for headlamp beam height control
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- status seat belt reminder passenger (off/on)
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- input signal anode/cathode for seat belt reminder.
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- Back-up (reverse) gear status. The parameter indicates whether the rear electronic module (REM) receives a signal indicating that the gear selector lever is in the back-up (R) position
  - Engaged = The gear selector lever is in the back-up (R) position
  - Disengaged = The gear selector lever is not in the back-up (R) position.
- Status, parking assistance rear. The parameter indicates whether the rear electronic module (REM) detects that the rear parking assistance system is active or not
  - On = The rear parking assistance system is active
  - Off = The rear parking assistance system is not active.
- Status, Distance behind. The parameter indicates the distance to a detectable object. The value of the parameter is transmitted by the rear electronic module (REM) on the controller area network (CAN). The distance is presented as a digit between 1 and 32
  - 1 = the distance from the rear bumper to the detectable object is approximately 1.5 m or greater
  - 2 to 31 = the distance to the detectable object is between approximately 1.5 m and approximately 0.3 m
  - 32 = the distance from the rear bumper to the detectable object is approximately 0.3 m or less.
- Status, back-up warning sensor 1-4. The parameter indicates whether the rear electronic module (REM) receives a status signal form the parking assistance module (PAM). This signal indicates whether there is a fault in the sensors or there terminals
  - Faulty = there is a fault in the back-up warning sensor or its terminals
  - OK = there is no fault in the back-up warning sensor or its terminals.

ACTIVATING COMPONENTS AND FUNCTIONS

This function can be used to activate components and functions which affect the outputs on the rear electronic module (REM).

The following components can be activated:

- activation of relay, simultaneous rear locking (rear doors and filler cap).
- activating the relay, left rear door locking
- activating the relay, left rear door unlocking
- activating the relay, deadlock for the rear doors
- activating the relay, right rear door locking
- activating the relay, right rear door unlocking
- activating the relay, rear folding head restraint
- activating the relay, tailgate pop-up
- activating the relay, fuel tank filler cap locking
- activating the relay, fuel tank filler cap unlocking
- activating the relay, rear fog lamp
- activating the relay for the rear fog lamp, German version and trailer
- activating the relay, back-up (reversing) lamp
- activating the relay, rear windshield heating
- activating the relay, tailgate wiper (5 doors)
- activating the relay, extended X-supply
- activating the relay, 15I power supply
- activating the relay, gas tank valve (CNG, Bi-fuel)
- activating the relay, rear A/C
- set assumed fuel level in the left tank half (10, 20, 30 or 40 liters)
- set assumed fuel level in the right tank half (10, 20, 30 or 40 liters)
- set assumed information about bulb failure monitoring (lamp fault)
- activating and deactivating the inclination sensor module (ISM)
- check "sleep mode" ("wake up" or "enter sleep"), inclination sensor module (ISM)
- assumed signal from the handle, tailgate pop-up
- activate the rear electronic module (REM) alarm trigger
- activate the cargo compartment lighting
- activate the back-up (reversing) warning.

READING OFF STATIC DATA

With this function programmed data can be read off. For the rear electronic module (REM), this indicates primarily which relays should be installed.

The following statistics can be read off:

- relay, left rear door locking
- relay, left rear door unlocking
- relay, rear door deadlock
- relay, right rear door locking
- relay, right rear door unlocking
- relay, tailgate pop-up
- relay, fuel tank filler cap locking
- relay, fuel tank filler cap unlocking
- relay, rear fog lamp
- relay, rear fog lamp, German version and trailer
- relay, back-up (reversing) lamp
- relay, rear windshield heating
- relay, increased X-supply
- relay, tailgate wiper
- relay, folding rear head restraint
- relay, 15I power supply
- relay, rear air conditioning (A/C)
- relay, gas tank valve
- relay, RMI 15, reserve
- relay, RMI 11, reserve
- relay, RMI 12, reserve.

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N
- P/N slave nodes (inclination sensor module (ISM))
- CAN frame period (40 ms for the CAN low-speed network at time of writing)
- Subcontractor identification plate (ECU-ID).

DIAGNOSTIC FUNCTIONS

GENERAL

The rear electronic module (REM) has a built-in diagnostic system, the Volvo on-board diagnostic (OBD)

system, which continuously monitors itself and the input and output signals.

DIAGNOSTIC TROUBLE CODES (DTC)

A diagnostic trouble code (DTC) is stored if the rear electronic module (REM) detects a fault. This control module can store up to 6 diagnostic trouble codes (DTCs), the 3 first and the 3 latest.

Should a fault disappear for any reason after being permanently stored in the control module as a diagnostic trouble code (DTC), the information remains stored in the memory.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function. The on-board diagnostic (OBD) system can identify 58 different faults in the rear electronic module (REM) in the form of diagnostic trouble codes (DTCs).

This function can also be used to read off whether the fault is still present (permanent) or whether it has now ceased (intermittent) after the diagnostic trouble code (DTC) has been stored.

Diagnostic trouble codes (DTC) can only be erased once all the diagnostic trouble codes (DTC) have been read off at least once.

READING OFF INPUT AND OUTPUT SIGNALS

This function can be used to continuously read off the values and status of the rear electronic module (REM) input and output signals.

The following parameters can be read off:

- status of the locking relay and unlocking relay for the left rear door
- status of the locking relay and unlocking relay for the right rear door
- status of the relay for the rear folding head restraint
- the status of the trunk lid pop-up relay (4 doors)
- status of the locking relay and unlocking relay for the fuel tank filler cover
- status of the rear fog lamp relay
- status of the rear fog lamp relay, German version and trailer
- status of the back-up lamp relay
- status of the rear windshield heating relay
- power supply from the rear electronic module (REM)
- fuel level, left and right tank halves
- input signal from the pressure sensor (CNG), Full (200bar): 4.5V Empty (0 bar): 0.5V)
- input signal from the temperature sensor (CNG) (5V - 0.5V) (0°C~4.5V, 25°C~3.6V)
- lamp fault. Indicates whether any bulb has blown. Parking lamp groups 1 and 2, cover the left and right rear parking lamps.

- the power supply to the inclination sensor module (ISM) (low, high). High when the car is alarmed, otherwise low
- Inclination sensor module (ISM), alarm status. Indicates whether the inclination sensor module (ISM) has deployed the alarm
- Inclination sensor module (ISM), x/y status. Indicates whether the inclination sensor module (ISM) has deployed first in the X or Y axis
- the status of the trunk lid handle, (pop up, no action) (4 doors)
- current, bulb failure warning sensor group 1 (left rear parking lamps). The rear electronic module (REM) detects lamp faults when the current is below 0.6A (4 doors) / 0.45A (5 doors)
- current, bulb failure warning sensor group 2 (right rear parking lamps). The rear electronic module (REM) detects lamp faults when the current is below 0.6A (4 doors) / 0.45A (5 doors)
- current, lamp fault rear fog lamp. The rear electronic module (REM) detects lamp faults when the current is below 1.5A
- Central electronic module (CEM) driver brake (off, on). Checks the input signal from the stop lamp driver from the central electronic module (CEM) to the rear electronic module (REM)
- stop lamp check (lamp on, lamp off). Checks whether the rear electronic module (REM) transmits a signal to activate the stop lamp relay
- current, lamp fault, stop lamp. The rear electronic module (REM) detects lamp faults when the current is below 3.0 A
- status of back-up gear (idle, engaged)
- status of the relay for the tailgate wiper. Controls starting and stopping the tailgate wiper (5 doors)
- status of the relay for extended X-supply. Controls the power supply to the tailgate wiper (5 doors)
- status relay 15I in the power supply
- status relay gas tank valve (Bi-fuel)
- status relay rear A/C
- cargo compartment lighting output signal (0W - 10W)
- position sensor input signal for the headlamp beam height control (1.7V -3.2V)
- calibration status of the position sensor for headlamp beam height control
- status seat belt reminder passenger (off/on)
- input signal anode/cathode for seat belt reminder.

ACTIVATING COMPONENTS AND FUNCTIONS

This function can be used to activate components and functions which affect the outputs on the rear electronic module (REM).

The following components can be activated:

- activation of relay, simultaneous rear locking (rear doors and filler cap).
- activating the relay, left rear door locking
- activating the relay, left rear door unlocking

- activating the relay, deadlock for the rear doors
- activating the relay, right rear door locking
- activating the relay, right rear door unlocking
- activating the relay, rear folding head restraint
- activating the relay, tailgate pop-up
- activating the relay, fuel tank filler cap locking
- activating the relay, fuel tank filler cap unlocking
- activating the relay, rear fog lamp
- activating the relay for the rear fog lamp, German version and trailer
- activating the relay, back-up (reversing) lamp
- activating the relay, rear windshield heating
- activating the relay, tailgate wiper (5 doors)
- activating the relay, extended X-supply
- activating the relay, 15I power supply
- activating the relay, gas tank valve (CNG, Bi-fuel)
- activating the relay, rear A/C
- set assumed fuel level in the left tank half (10, 20, 30 or 40 liters)
- set assumed fuel level in the right tank half (10, 20, 30 or 40 liters)
- set assumed information about bulb failure monitoring (lamp fault)
- activating and deactivating the inclination sensor module (ISM)
- check "sleep mode" ("wake up" or "enter sleep"), inclination sensor module (ISM)
- assumed signal from the handle, tailgate pop-up
- activate the rear electronic module (REM) alarm trigger
- activate the cargo compartment lighting
- activate the back-up (reversing) warning.

READING OFF STATIC DATA

With this function programmed data can be read off. For the rear electronic module (REM), this indicates primarily which relays should be installed.

The following statistics can be read off:

- relay, left rear door locking
- relay, left rear door unlocking
- relay, rear door deadlock
- relay, right rear door locking
- relay, right rear door unlocking
- relay, tailgate pop-up

- relay, fuel tank filler cap locking
- relay, fuel tank filler cap unlocking
- relay, rear fog lamp
- relay, rear fog lamp, German version and trailer
- relay, back-up (reversing) lamp
- relay, rear windshield heating
- relay, increased X-supply
- relay, tailgate wiper
- relay, folding rear head restraint
- relay, 15I power supply
- relay, rear air conditioning (A/C)
- relay, gas tank valve
- relay, RMI 15, reserve
- relay, RMI 11, reserve
- relay, RMI 12, reserve.

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N
- P/N slave nodes (inclination sensor module (ISM))
- CAN frame period (40 ms for the CAN low-speed network at time of writing)
- Subcontractor identification plate (ECU-ID).

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the rear electronic module (REM). When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

The control module is mounted in a relay box behind the left-hand cargo compartment panel. To replace the rear electronic module (REM), remove it from the relay box.

For cars with Bi-Xenon lamps, the position sensor for headlamp range adjustment must be calibrated when the control module is replaced. This is carried out in VIDA via the vehicle communication socket.

FUNCTION

FUEL LEVEL

Fig. 167: Fuel Level Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

The fuel level is gauged by the fuel level sensors (7/130, 7/143). The signals from the sensors are transmitted to the rear electronic module (REM) (4/58). The rear electronic module (REM) calculates the quantity of fuel remaining by comparing the signals with a tank table stored in the rear electronic module (REM). Information about the quantity of fuel is transmitted via the Control area network (CAN) to the driver information module (DIM) (5/1) where the fuel level is displayed on the fuel gauge.

FUEL LEVEL (BI-FUEL)

Fig. 168: Fuel Level Input And Output Signals (Bi-Fuel)
Courtesy of VOLVO CARS CORPORATION

The fuel level in the gasoline tank is measured by the fuel level sensor (7/143). The level in the gas tank is measured by the fuel level sensor (7/156) (CNG) or (7/153) (LPG). The signals from the sensors are transmitted to the rear electronic module (REM) (4/58).

The rear electronic module (REM) calculates the quantity of fuel remaining in each tank and transmits this information via the Control area network (CAN) to the driver information module (DIM) (5/1). The driver information module (DIM) also receives data via the Control area network (CAN) from the engine control module (ECM) (4/46) indicating which type of fuel the car is running on. The gas level in the tank is displayed via the fuel gauge. The gasoline fuel level is displayed in the text window in the driver information module (DIM).

SHUT-OFF VALVE (BI-FUEL)

Fig. 169: Identifying Shut-Off Valve Input And Output Signals (Bi-Fuel)
Courtesy of VOLVO CARS CORPORATION

The rear electronic module (REM) (4/58) controls the shut-off valves, (8/88-90) (CNG) and (8/76) (LPG), via a directly connected relay (2/140) which supplies the valves with power when they should be open.

The rear electronic module (REM) receives information via the control area network (CAN) from the engine control module (ECM) (4/46) indicating that the car should run on gas/LPG. The rear electronic module (REM) also receives information via the control area network (CAN) from the central electronic module (CEM) (4/56) indicating the position of the ignition and data about collision status. When the ignition is on and no collision has been registered, the rear electronic module (REM) activates the relay, which supplies the valves with power.

The rear electronic module (REM) deactivates the relay in the following cases:

- there is a signal from the engine control module (ECM) indicating that gasoline operation has been selected
- ignition off
- the collision status changes
- there is a fault in the communication on the controller area network (CAN).

The relay can be activated via a diagnostic command to, for example, allow the tank to be drained. Activation is carried out in VIDA via the vehicle communication socket.

REAR FOG LAMP

Fig. 170: Identifying Rear Fog Lamp Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

The rear fog lamps (10/46, 10/53) are activated by pressing the button for the rear fog lamps in the lamp switch module (3/111). The light switch module (LSM) transmits a request to light the lamps to the central electronic module (CEM) (4/56) using serial communication. The central electronic module (CEM) transmits the request to the rear electronic module (REM) (4/58) via the Controller area network (CAN). The rear electronic module (REM) activates the relay (2/49) and the lamps are supplied with power via the relay.

Central Electronic Module (CEM) transmits information:

- back to the light switch module (LSM) to light the LED in the button
- via the Controller area network (CAN) to the driver information module (DIM) (5/1) to light the indicator lamp for the rear fog lamps.

Information about the lamp circuit is obtained by the rear electronic module (REM) via a shunt (20/29). The rear electronic module (REM) sends the status of the lamp fault via the Control area network (CAN) to the central electronic module (CEM). In the event of a fault, the central electronic module (CEM) transmits data via the Control area network (CAN) to the driver information module (DIM) which displays a text message.

BACK-UP LAMP

Fig. 171: Back-Up Lamp Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

Manual transmissions

The back-up (reversing) lamps (10/48, 10/55) are activated when back-up (reverse) gear is selected. The switch (3/10) on the transmission is then closed. A directly connected signal is transmitted to the central electronic module (CEM) (4/56) indicating that back-up (reverse) gear is selected. The central electronic module (CEM) transmits the information via the controller area network (CAN) to the rear electronic module (REM) (4/58) to activate the back-up lamps. The rear electronic module (REM) activates the relay (2/80) and the lamps are supplied with power via the relay.

Automatic transmission

The back-up (reversing) lamps (10/48, 10/55) are activated when back-up (reverse) gear is selected. The transmission control module (TCM) (4/28) transmits information via the Control area network (CAN) to the central electronic module (CEM) (4/56) indicating that back-up (reverse) gear is selected. The central electronic module (CEM) transmits the information via the controller area network (CAN) to the rear electronic module (REM) (4/58) to activate the back-up lamps. The rear electronic module (REM) activates the relay (2/80) and the lamps are supplied with power via the relay.

BRAKE LIGHT

Fig. 172: Brake Light Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

The stop lamps (10/43, 10/50) are activated when the brake switch is (3/9) closed. A directly connected signal is transmitted via the central electronic module (CEM) (4/56) to the rear electronic module (REM) (4/58) and activates the relay (2/79). The lamps are powered via the relay. The central electronic module (CEM) transmits the data via the Controller area network (CAN) to the rear electronic module (REM) indicating that the stop lamp switch is activated. Information about the lamp circuit is obtained by the rear electronic module (REM) via a shunt (20/31). The rear electronic module (REM) sends status information for the lamp fault via the Control area network (CAN) to the central electronic module (CEM). In the event of a fault, the central electronic module (CEM) transmits data via the Control area network (CAN) to the driver information module (DIM) (5/1) which displays a text message.

HIGH LEVEL STOP LAMP

Fig. 173: High Level Stop Lamp Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

When the stop lamp switch (3/9) is closed, a signal is transmitted to the central electronic module (CEM) (4/56). The signal is transmitted from the central electronic module (CEM) to the rear electronic module (REM) (4/58) via a directly connected cable. The high mounted stop lamp is supplied with power directly from the rear electronic module (REM). The stop lamp is supplied with power for as long as the stop lamp switch is closed.

REAR DEMIST

Fig. 174: Identifying Rear De-Mist Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

Rear demist (9/2) is activated by pressing the switch on the climate control module (CCM) (3/112). The climate control module (CCM) transmits the data via the Control area network (CAN) to the central electronic module (CEM) (4/56). The central electronic module (CEM) checks that the conditions to start the demist have been met. If the conditions are met, a request is sent via the Control area network (CAN) to the rear electronic module (REM) (4/58) to activate the relay (2/82). The rear electronic module (REM) powers the relay and the demister is powered.

The central electronic module (CEM) also transmits a request via the Control area network (CAN) back to the climate control module (CCM) to light the LED in the switch.

CARGO COMPARTMENT LIGHTING

Fig. 175: Cargo Compartment Lighting Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

The cargo compartment lighting is activated when the trunk lid is opened. The central electronic module (CEM) (4/56) receives a signal from the lock (3/78) in the trunk lid. The central electronic module (CEM) transmits the information via the Controller area network (CAN) to the rear electronic module (REM) (4/58) about the status of the trunk lid. A request for cargo compartment lighting is also sent from the upper electronic module (UEM) (4/70) to the rear electronic module (REM). The lamps (10/173 (XC90)) are then powered directly from the rear electronic module (REM).

For the XC90, the roof lamp in the cargo compartment also lights.

REAR 12 V SOCKET

Fig. 176: Identifying Rear 12 V Socket Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

When a power consuming component is connected to the rear 12V socket (17/19), the power consumption is measured via a directly connected shunt (20/39) on the rear electronic module (REM) (4/58). The rear electronic module (REM) transmits status data via the control area network (CAN) to the driver information module (DIM) (5/1) which displays a text message (applies only to factory mounted 12V sockets).

The text message is also displayed if a power consuming component is connected when changing from ignition position:

- II to I
- I to 0 and
- 0 to the key is removed.

There is also an audible warning note when the key is removed.

PARKING ASSISTANCE (APPLIES ONLY TO THE XC90 2003-2004)

Fig. 177: Identifying Parking Assistance Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

The back-up (reverse) warning system is activated by pressing the switch on the climate control module (CCM) (3/112). Information about the position of the switch is sent via the Control area network (CAN) to the rear electronic module (REM) (4/58). When back-up (reverse) warning is selected, this is confirmed by the rear electronic module (REM) sending a signal back to the climate control module (CCM) to light the LED in the switch.

The rear electronic module (REM) also receives information via the Control area network (CAN) from the central electronic module (CEM) (4/56) about:

- the key position and
- that back-up (reverse) gear is selected.

The parking assistance system can detect nearby objects when the ignition is on in position II and back-up gear (R) is selected. The parking assistance system is deactivated automatically when the gear selector lever is moved from (R) to any other position.

When the conditions for activating the back-up (reverse) warning are met, the rear electronic module (REM) sends data via serial communication to the parking assistance module (PAM) (4/86). The parking assistance module (PAM) receives signals from the back-up (reversing) warning sensors. A signal for sound from the parking assistance system is sent back from the parking assistance module (PAM) via the rear electronic module (REM) to the infotainment control module (ICM) (16/94). The parking assistance module (PAM) sends the signal when there is an object within 1.5 meters of the rear of the car.

The Infotainment Control Module (ICM) display a text message that the back-up (reversing) warning is active. The Infotainment Control Module (ICM) also sends information via the MOST network to the Audio Control Module (AUD) (16/105). The information which is sent contains the time interval between the acoustic tones as well as the muting of other sound, e. g. CD or radio. The Audio Control Module (AUD) playback the sound in the right-hand rear loudspeaker (16/5).

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 178: Central Electronic Module Control module
Courtesy of VOLVO CARS CORPORATION

The rear electronic module (REM) handles functions for:

- alarm (certain functions)
- locks (certain functions)
- inclination sensor module (ISM)
- headlamp range adjustment position sensors (Bi-Xenon)
- fuel level

- fuel level (Bi-fuel)
- shut-off valve (Bi-fuel)
- rear fog lamps
- back-up lamp
- stop lamps
- high level stop lamps
- rear windshield wiper/washers
- rear demist
- cargo compartment lighting
- rear 12 V socket
- parking assistance (applies only to the XC90 2003-2004).

The control module is installed as a separate unit in the rear relay box. This is under the left-hand cargo compartment panel.

The rear electronic module (REM) communicates with components which are directly connected and also with other control modules and components via serial communication and the control area network (CAN).

The control module checks activations and input and output signals using an integrated diagnostic system A diagnostic trouble code (DTC) is stored if the control module detects an error. In certain cases the control module replaces the faulty signal with a substitute value.

Any diagnostic trouble codes (DTCs) are stored in the control module memory. This information can be read off using VIDA via the data link connector (DLC) in the car.

Lock and unlock the rear doors to check whether the rear electronic module (REM) is grounded and powered. The control module is powered and grounded if the doors lock and unlock. Another way to check whether the rear electronic module (REM) is powered and grounded is to switch on the rear fog lamp.

SIGNALS

The following table summarizes input signals to and output signals from the rear electronic module (REM). The signal types are divided into directly connected signals, serial communication and controller area network (CAN) communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: • Fuel level sensor (7/130, 7/143) • Fuel level sensor (CNG) (7/156) • Fuel level sensor (LPG) (7/153) • Stop lamps from the central electronic module (CEM) (4/56)	**Directly connected:** • Fuel level sensor (CNG) (7/156) • Rear demist, relay (9/2) • Cargo compartment lighting (10-127-128, 10/173) • High level stop lamp (10/19)

• Position sensor for headlamp range adjustment (Bi-Xenon) (7/120)	• Position sensor for headlamp range adjustment (Bi-Xenon) (7/120) • Inclination sensor module (ISM) (7/100).
Via serial communication: • Inclination sensor module (ISM) (optional extra) (7/100) • Parking assistance (optional extra) (4/86) (applies only to the XC90 2003-2004).	**Via serial communication:** • Inclination sensor module (ISM) (optional extra) (7/100) • Parking assistance (optional extra) (4/86) (applies only to the XC90 2003-2004).
Via Controller Area Network (CAN) communication: • Climate Control Module (CCM) (3/112) • Central electronic module (CEM) (4/56) • Engine control module (ECM) (4/46) • Supplemental Restraint System Module (SRS) (4/9) • Upper electronic module (UEM) (4/70).	**Via Controller Area Network (CAN) communication:** • Climate Control Module (CCM) (3/112) • Central electronic module (CEM) (4/56) • Driver information module (DIM) (5/1) • Infotainment control module (ICM) (16/1) (XC90) • Phone module (PHM) (optional equipment) (16/60) • Supplemental Restraint System Module (SRS) (4/9) • Transmission control module (TCM) (4/28).

Fig. 179: Identifying Rear Electronic Module Input And Output Signals

Courtesy of VOLVO CARS CORPORATION

REAR ELECTRONIC MODULE (REM) (2005-2012)

DESIGN

INCLINATION SENSOR MODULE (ISM) (XC90 STRUCTURE WEEK -201127)

Fig. 180: Identifying Inclination Sensor Module
Courtesy of VOLVO CARS CORPORATION

The inclination sensor module (ISM) is on the left-hand side of the rear relay box.

The inclination sensor module (ISM) is powered from the rear electronic module (REM), which both activates and deactivates it. Information is transferred from the inclination sensor module (ISM) to the rear electronic module (REM) using serial communication.

The inclination sensor module (ISM) detects when the angle of the vehicle changes. If the angle changes when the vehicle is alarmed, a signal is transmitted to the rear electronic module (REM) which sends this information out on the controller area network (CAN) to activate the alarm.

There are diagnostics for the Inclination Sensor Module (ISM).

INCLINATION SENSOR MODULE ALARM (BBS-IS) (XC90 STRUCTURE WEEK 201128-)

Fig. 181: Locating Inclination Sensor Module Alarm
Courtesy of VOLVO CARS CORPORATION

If the vehicle is equipped with a vehicle inclination sensor, the sensor is integrated in the siren. The vehicle inclination sensor reacts to changes in the angle of lean of the vehicle and transmits a signal to the Rear electronic module (REM). While the vehicle inclination sensor is mounted in the siren it is counted as a separate unit. If the vehicle inclination sensor indicates that the vehicle is being lifted the master control module must send an activation signal to the siren. In this case the siren cannot trigger an alarm by itself.

The siren is powered via a fuse from the central electronic module (CEM) The siren is grounded in the engine compartment.

SIREN (BBS) (XC90 STRUCTURE WEEK 201128-)

Fig. 182: Locating Inclination Sensor Module Alarm
Courtesy of VOLVO CARS CORPORATION

The siren is used as a sound source for the alarm function. The siren is located in a protected position under the fender liner in the front right wheel housing. The siren is available in versions with or without an internal vehicle inclination sensor. The type of siren installed in the vehicle depends on the market and the customer's wishes.

The siren will sound if the power supply to it is broken or if communication with the master control module ends when the alarm is activated. The siren contains an internal battery that is charged when the ignition is on or

engine running.

The battery service life is limited and depends on the local climate. The battery cannot be replaced as an individual component. The alarm cause can be read from VIDA (Volvo scan tool). This states what caused the alarm.

The siren is powered via a fuse from the central electronic module (CEM) The siren is grounded in the engine compartment.

There are diagnostics for the siren.

HEADLAMP RANGE ADJUSTMENT POSITION SENSORS (BI-XENON)

Fig. 183: Headlamp Range Adjustment Position Sensors (Bi-Xenon)
Courtesy of VOLVO CARS CORPORATION

Cars with Bi-Xenon lamps have a position sensor so that the headlamps can automatically adjust beam length. The vertical adjustment accounts for load and road conditions to reduce the risk of dazzle.

The position sensor is beside the rear axle and is connected to the left-hand rear control arm by a linkage system. This linkage system affects the sensor, allowing the angle of the car to be gauged.

The position sensor is directly connected to the rear electronic module (REM) via three inputs. Two are used for the power supply and ground connection for the sensor. One input is used for signals about the angle of the car. The signals are received by the rear electronic module (REM) which sends them onwards via the Control area network (CAN) to the central electronic module (CEM) which controls the headlamp range adjustment function.

The position sensor can be calibrated using VIDA (Volvo scan tool). The calibration is saved in the rear electronic module (REM) and must be carried out again if the rear electronic module (REM) or position sensor is replaced.

There are diagnostics for the position sensor.

FUEL LEVEL (BI-FUEL)

Fig. 184: Fuel Level Sensor (Bi-Fuel)
Courtesy of VOLVO CARS CORPORATION

CNG (Compressed Natural Gas)

The fuel level in the gasoline tank operates in the same way as for vehicles with B5244S6 engines, using a sensor in the gasoline tank. A combined pressure and temperature sensor is used to measure the fuel level in the gas tank. The sensor is on the left-hand side of the gas tank.

The sensor is directly connected to the rear electronic module (REM). The signals from the sensor are transmitted to the rear electronic module (REM) where they are calculated and sent to the driver information module (DIM) and engine control module (ECM) via the controller area network (CAN).

There are diagnostics for the fuel level sensor.

LPG (Liquefied Petroleum Gas)

The fuel level in the gasoline tank operates in the same way as for vehicles with B5244S6 engines, using a sensor in the gasoline tank.

A sensor, on the right-hand side of the tank, is used to measure the fuel level in the LPG tank. The sensor is directly connected to the rear electronic module (REM). The signals from the sensor are compared with a table stored in the rear electronic module (REM). Data about the remaining volume of fuel is transmitted to the driver information module (DIM) and engine control module (ECM) via the controller area network (CAN).

There are diagnostics for the fuel level sensor.

SHUT-OFF VALVE (BI-FUEL)

Fig. 185: Identifying Shut-Off Valve (Bi-Fuel)
Courtesy of VOLVO CARS CORPORATION

There are shut-off valves on the gas tanks to open and close the tank valves on bi-fuel cars.

These are positioned at the inlet and outlet on each gas tank. There is one for LPG and three for CNG.

The valves are controlled electro-magnetically and powered via a relay directly connected to the rear electronic module (REM). The rear electronic module (REM) activates the relay when a request for gas power is transmitted on the controller area network (CAN) by the engine control module (ECM).

The valves close when the vehicle is running on gasoline, when the ignition is switched off or in the event of a collision.

The valves can be opened via a diagnostic command by activating the relay for the gas valves. Activation is carried out in VIDA vehicle communication.

The valves for the CNG tanks can also be closed manually using an Allen key.

There are diagnostics for the shut-off valve relay.

REAR FOG LAMP

Fig. 186: Identifying Rear Fog Lamp And Back-Up Lamp

Courtesy of VOLVO CARS CORPORATION

The rear fog lamp are in the tail lamps. The fog lamps are operated via a button in the light switch module (LSM). An LED in the button lights when the fog lamps are activated. The rear fog lamp can only be activated when low beam is on (market dependent). The light switch transmits information to the central electronic module (CEM) using serial communication when the button for the rear fog lamp is pressed. The central electronic module (CEM) transmits the data via the Controller area network (CAN) to the rear electronic module (REM). The power supply for the lamps is via a directly connected relay in the rear electronic module (REM).

When reactivating key position II, the function is set to non-activated mode.

To detect faults in the rear fog lamps, the rear electronic module (REM) reads the power consumption of the circuit. If the power consumption falls below a certain limit, a fault is indicated and a text message is displayed in the driver information module.

REAR PARKING LAMPS/LICENSE PLATE LIGHTING

Fig. 187: Identifying Rear Parking Lamps/License Plate Lighting
Courtesy of VOLVO CARS CORPORATION

There are a number of lamps positioned around the car to mark its position. These are in the headlamps and tail lamps. The lamps light together with the license plate lighting when the light switch module (LSM) is in parking lamp mode or low beam is on.

The rear parking lamps and license plate lighting are powered by the rear electronic module (REM).

The front parking lamps are powered by the central electronic module (CEM).

There are diagnostics for the rear parking lamps and license plate lighting.

BACK-UP LAMP

Fig. 188: Identifying Rear Fog Lamp And Back-Up Lamp
Courtesy of VOLVO CARS CORPORATION

There are two back-up (reversing) lamps. These are in the tail lamps. The back-up (reversing) lamp lights when back-up (reverse) gear is selected. The back-up (reversing) lamps are connected to the rear electronic module (REM) via an internal directly connected relay. The lamps are powered via the relay.

Cars with manual transmissions

Cars with manual transmissions have a back-up (reverse) switch on the transmission. The switch closes and transmits a directly connected signal to the central electronic module (CEM) when back-up (reverse) gear is selected.

Cars with automatic transmissions

In cars with automatic transmissions, a signal is transmitted from the transmission control module (TCM) on the controller area network (CAN) to the central electronic module (CEM) indicating that back-up (reverse) gear is selected.

BRAKE LIGHT

Fig. 189: Identifying Rear Fog Lamp And Back-Up Lamp
Courtesy of VOLVO CARS CORPORATION

The stop lamps are in the tail lamps. The lamps light when the stop lamp switch on the brake pedal is closed. The stop lamp switch is connected to the central electronic module (CEM). The signal from the stop lamp switch is sent on to the rear electronic module (REM) via a hardwired cable. The power supply for the lamps is via a directly connected relay in the rear electronic module (REM). In order for the stop lamps to work when the ignition is not on, there is no logic in the rear electronic module (REM) to activate the relay. The relay is activated directly by the signal from the stop lamp switch. The rear electronic module (REM) receives data via the controller area network (CAN) from the central electronic module (CEM) indicating that the stop lamp switch is activated.

To detect faults in the stop lamps, the rear electronic module (REM) reads the power consumption of the lamp circuit. If the power consumption falls below a certain limit, a fault is indicated and a text message is displayed in the driver information module.

There are diagnostics for the stop lamps.

HIGH LEVEL STOP LAMP

Fig. 190: High Level Stop Lamp
Courtesy of VOLVO CARS CORPORATION

There is a high-mounted stop lamp on the inside of the rear windshield. This lamp lights during braking together with the standard stop lamps. The stop lamp is activated when the stop lamp switch on the brake pedal is closed.

The high mounted stop lamp is supplied with power directly from the rear electronic module (REM). The lamp consists of a number of LEDs.

There are diagnostics for the high level stop lamp.

REAR DEMIST

Fig. 191: Identifying Rear De-Mist
Courtesy of VOLVO CARS CORPORATION

There are heating loops in the glass for demisting and to prevent ice from forming. The loops heat up when they are supplied with power. The power supply is via a directly connected relay in the rear electronic module (REM).

Rear demist is controlled using a switch on the right-hand side of the climate control module (CCM).

The engine must be running for the demister to work. Press the button again to switch off the function. Demisting is switched off automatically after the maximum time of 12 minutes.

There are diagnostics for the switch via the climate control module (CCM).

CARGO COMPARTMENT LIGHTING

Fig. 192: Cargo Compartment Lighting
Courtesy of VOLVO CARS CORPORATION

There are lamps in the cargo compartment. In the XC90 there is a lamp in the trunk lid. The lamps light when the trunk lid is open. The cargo compartment lighting is powered directly from the rear electronic module (REM).

There are diagnostics for the cargo compartment lighting.

REAR 12V SOCKET

Fig. 193: Identifying Rear 12V Socket
Courtesy of VOLVO CARS CORPORATION

There is a 12V socket on the right-hand side of the cargo compartment. This socket can be used to power a number of accessories.

The socket is directly connected to the 30-supply via a fuse on the rear electronic module (REM).

The rear electronic module (REM) measures the power consumption and calculates an average value. This is compared with a limit value to determine if any power consuming component is connected.

This information is transmitted via the controller area network (CAN) to the driver information module (DIM) which displays a text message when a power consuming component is connected.

PARKING ASSISTANCE SYSTEM (OPTIONAL EXTRA)

Fig. 194: Identifying Parking Assistance System
Courtesy of VOLVO CARS CORPORATION

There is a parking assistance system to assist parking. The parking assistance system consists of:

- four parking sensors in the rear bumper

- four parking sensors in the front bumper (option)
- the parking assistance module (PAM) under the rear relay box.

The parking assistance module (PAM) communicates with the rear electronic module (REM) using serial communication. The signals transmitted contain information about status and diagnostics. The sensors are directly connected to the parking assistance module (PAM). The sensors are also powered via the parking assistance module (PAM).

The parking assistance module (PAM) is powered and grounded via the rear electronic module (REM).

The parking assistance system is activated via a switch on the dashboard environment panel for the climate control module (CCM). An LED lights in the switch when the system is active.

The rear sensors detect objects within 1.5 meters if back-up (reverse) gear is selected. There is a beeping noise from the rear loudspeakers. The sound intensifies as the vehicle gets nearer to the object. The sound is constant from approximately 30 cm.

The front sensors (option) detect objects within 0.8 meters if back-up gear is selected or if the car is driven forwards at a speed below 10 km/h. There is a beeping sound from one of the front loudspeakers. The sound intensifies as the vehicle gets nearer to the object. The sound is constant from approximately 30 cm.

In the event of a fault in the parking assistance module (PAM) or sensors, the general warning lamp in the driver information module (DIM) lights and a text message is displayed.

The parking assistance system can be temporarily deactivated at lower speeds. This is done manually using a switch on the dashboard environment panel for the climate control module (CCM). The LED in the switch goes out when the system is deactivated.

There are diagnostics for the parking assistance system

TOW HITCH (OPTIONAL EXTRA)

Fig. 195: Identifying Trailer Module (TRM)
Courtesy of VOLVO CARS CORPORATION

The trailer module (TRM) manages the electrical connection between the vehicle and the trailer. The trailer module (TRM) is directly connected to the rear electronic module (REM).

The primary task of the trailer module (TRM) is to manage output signals to the tow hitch cable harness for:

- Turn signal lamps
- Brake light
- Parking lamps
- Fog lights

The rear electronic module (REM) transmits the following voltages to the electrical socket for the tow hitch:

- Back-up lamp
- +12V voltage
- +12V supply.

REAR WINDOW LIFT MECHANISMS

Fig. 196: Identifying Rear Window Lift Mechanisms
Courtesy of VOLVO CARS CORPORATION

The rear side windows are operated by motors in the doors. The switches for operating the windows are in the door panels. The windows can also be operated from the driver's door module (DDM).

The function is controlled by five relays inside the rear electronic module (REM). Depending on whether the control switch is moved up or down, the relays are activated to carry out the requested operation.

Two relays guide the window up on the right and left-hand sides. Two other relays lower the window. A further relay controls the power supply.

When operated from the driver's position, information is transmitted via the controller area network (CAN) from the driver's door module (DDM) to the rear electronic module (REM) which sends out signals to the relays.

DIAGNOSTIC FUNCTIONS

GENERAL

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. The control module can store up to 6 diagnostic trouble codes (DTCs). A fault which is detected in the most recent operating cycle is defined as permanent. Other faults which are detected are defined as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N.

READING OFF EXTENDED DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION

This function can be used to read parameters, status identifiers and counters stored at the same time as a diagnostic trouble code (DTC). These are called frozen values.

For further information, see: **DESCRIPTION OF FROZEN VALUES, REAR ELECTRICAL MODULE**

READING OFF THE PARAMETER VALUES

Using this function, the status or value of parameters can be read off. The status/value is presented digitally.

For further information about the different parameters, see: **DESCRIPTION OF PARAMETERS**

ACTIVATING COMPONENTS AND FUNCTIONS

This function can be used to activate components and functions which affect the outputs on the rear electronic

module (REM).

For further information, see: **DESCRIPTION OF ACTIVATIONS**

DESCRIPTION OF FROZEN VALUES, REAR ELECTRICAL MODULE

EXPLANATION

Not all the parameters described need to be implemented in the control module. This varies from system to system.

Frozen values are parameter values that are stored when a diagnostic trouble code (DTC) is stored.

BATTERY VOLTAGE, VALUE

Measurement range: 0-12 V.

Normal value when the generator (GEN) is charging: 13.0-14.5 V.

The value is the voltage from the central electronic module (CEM).

DISTANCE, VALUE

Measurement range: 0-1048575 km.

The value indicates the total mileage of the car at the time the diagnostic trouble code (DTC) was stored.

PASSENGER COMPARTMENT TEMPERATURE, VALUE

Measurement range: -60-195 °C.

The combined instrument panel obtains the value via the control area network (CAN).

OUTSIDE TEMPERATURE, VALUE

Measurement range: -128-127.75 °C.

The combined instrument panel obtains the value via the control area network (CAN).

ENGINE RUNNING, STATUS

The status displays whether the engine was running when the diagnostic trouble code (DTC) was stored.

No = the engine was not running

Yes = the engine was running

TIME, VALUE

The value displays the time that has passed since the diagnostic trouble code (DTC) was stored.

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the rear electronic module (REM). When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

The control module is mounted in a relay box behind the left-hand cargo compartment panel. To replace the rear electronic module (REM), remove it from the relay box.

For cars with Bi-Xenon lamps, the position sensor for headlamp range adjustment must be calibrated when the control module is replaced. This is carried out in VIDA via the vehicle communication socket.

FUNCTION

BATTERY VOLTAGE

The task of the rear electronic module (REM) is to check the voltage of the battery. The value of the voltage is transmitted out on the CAN network as a reference for other control modules.

The Central electronic module (CEM) receives this signal and checks it against its own supply voltage from the battery. The value is used when diagnosing the charging function.

FUEL LEVEL (BI-FUEL)

Fig. 197: Identifying Fuel Level Measurement System And Components
Courtesy of VOLVO CARS CORPORATION

The fuel level in the gasoline tank is measured by the fuel level sensor (7/143). The level in the gas tank is measured by the fuel level sensor (7/156) (CNG) or (7/153) (LPG). The signals from the sensors are transmitted to the rear electronic module (REM) (4/58).

The rear electronic module (REM) calculates the quantity of fuel remaining in each tank and transmits this information via the controller area network (CAN) to the driver information module (5/1) and engine control module (ECM) (4/46). The driver information module (DIM) also receives data via the controller area network (CAN) from the engine control module (ECM) (4/46) indicating which type of fuel the car is running on. The gas level in the tank is displayed via the fuel gauge. The gasoline fuel level is displayed in the text window in the driver information module (DIM).

SHUT-OFF VALVE (BI-FUEL)

Fig. 198: Identifying Bi-Fuel Shut-Off Valve Communication Links & Components
Courtesy of VOLVO CARS CORPORATION

The rear electronic module (REM) (4/58) controls the shut-off valves, (8/88-90) (CNG) and (8/76) (LPG), via a relay (which supplies the valves with power when they should be open.

The rear electronic module (REM) receives information via the controller area network (CAN) from the engine control module (ECM) (4/46) indicating that the car should run on LPG or CNG. The rear electronic module (REM) also receives information via the controller area network (CAN) from the central electronic module (CEM) (4/56) indicating the position of the ignition and data about collision status. When the ignition is on and no collision has been registered, the rear electronic module (REM) activates the relay, which supplies the valves with power.

The rear electronic module (REM) deactivates the relay in the following cases:

- there is a signal from the engine control module (ECM) indicating that gasoline operation has been selected
- ignition off
- the collision status changes
- there is a fault in the communication on the controller area network (CAN).

The relay can be activated via a diagnostic command, for example, to allow the tank to be drained. Activation is carried out in VIDA via the vehicle communication socket.

REAR FOG LAMP

Fig. 199: Identifying Rear Fog Lamp(s) Communication Links & Components
Courtesy of VOLVO CARS CORPORATION

The rear fog lamps (10/46, 10/53) are activated by pressing the button for the rear fog lamps in the lamp switch module (3/111). The light switch module (LSM) transmits a request to light the lamps to the central electronic module (CEM) (4/56) using serial communication. The central electronic module (CEM) transmits the request to the rear electronic module (REM) (4/58) via the Controller area network (CAN).

Central Electronic Module (CEM) transmits information:

- back to the light switch module (LSM) to light the LED in the button
- via the Controller area network (CAN) to the driver information module (DIM) (5/1) to light the indicator lamp for the rear fog lamps.

The rear electronic module (REM) sends the status of the lamp fault via the Control area network (CAN) to the central electronic module (CEM). In the event of a fault, the central electronic module (CEM) transmits data via the Control area network (CAN) to the driver information module (DIM) which displays a text message.

REAR PARKING LAMPS/LICENSE PLATE LIGHTING

Fig. 200: Identifying Rear Parking Lamps/License Plate Lighting Communication Links & Components
Courtesy of VOLVO CARS CORPORATION

The parking lamps (10/17-18) and license plate lighting (10/3) light when:

- the knob in the light switch module (LSM) (3/111) is in the low beam position
- the knob in the light switch module (LSM) is in the parking lamp position
- low beam is lit via the low beam automatic function.

The lamp switch module (LSM) transmits data using serial communication to the central electronic module (CEM) (4/56) to activate the lamps.

The central electronic module (CEM) transmits the data via the controller area network (CAN) to the rear electronic module (REM) which activates the lamps.

The rear parking lamps and license plate lighting are powered via the rear electronic module (REM) (4/58).

In the event of a bulb fault for the rear parking lamps or license plate lighting, data is transmitted on the controller area network (CAN) from the rear electronic module (REM) to the driver information module (DIM) (5/1) and a text message is displayed.

There is a Limp Home function for the parking lamps so that they will work even if there is a fault in the controller area network (CAN) or in the serial communication between the light switch module (LSM) and the

central electronic module (CEM).

BACK-UP LAMP

Fig. 201: Identifying Back-Up Lamp Communication Links And Components
Courtesy of VOLVO CARS CORPORATION

Manual transmissions

The back-up (reversing) lamps (10/48, 10/55) are activated when back-up (reverse) gear is selected. The switch (3/10) on the transmission is then closed. A directly connected signal is transmitted to the central electronic module (CEM) (4/56) indicating that back-up (reverse) gear is selected. The central electronic module (CEM) transmits the information via the controller area network (CAN) to the rear electronic module (REM) (4/58) to activate the back-up lamps. The rear electronic module (REM) activates the relay and the back-up lamps are supplied with power via the relay.

Automatic transmission

The back-up (reversing) lamps (10/48, 10/55) are activated when back-up (reverse) gear is selected. The transmission control module (TCM) (4/28) transmits information via the Control area network (CAN) to the central electronic module (CEM) (4/56) indicating that back-up (reverse) gear is selected. The central electronic module (CEM) transmits the information via the controller area network (CAN) to the rear electronic module (REM) (4/58) to activate the back-up lamps. The rear electronic module (REM) activates the relay and the back-up lamps are supplied with power via the relay.

BRAKE LIGHT

Fig. 202: Identifying Brake Light Communication Links And Components
Courtesy of VOLVO CARS CORPORATION

The stop lamps (10/43, 10/50) are activated when the brake switch is (3/9) closed. A directly connected signal is transmitted via the central electronic module (CEM) (4/56) to the rear electronic module (REM) (4/58) and activates the relay. The lamps are powered via the relay. The central electronic module (CEM) transmits the data via the Controller area network (CAN) to the rear electronic module (REM) indicating that the stop lamp switch is activated. The rear electronic module (REM) sends status information for the lamp fault via the Control area network (CAN) to the central electronic module (CEM). In the event of a fault, the central electronic module (CEM) transmits data via the Control area network (CAN) to the driver information module (DIM) (5/1) which displays a text message.

HIGH LEVEL STOP LAMP

Fig. 203: Identifying High Level Stop Lamp Communication Links & Components
Courtesy of VOLVO CARS CORPORATION

When the stop lamp switch (3/9) is closed, a signal is transmitted to the central electronic module (CEM) (4/56). The signal is transmitted from the central electronic module (CEM) to the rear electronic module (REM) (4/58) via a directly connected cable. The high mounted stop lamp is supplied with power directly from the rear electronic module (REM). The stop lamp is supplied with power for as long as the stop lamp switch is closed.

REAR DEMIST

Fig. 204: Identifying Rear Demister Communication Links & Components
Courtesy of VOLVO CARS CORPORATION

Rear demist (9/2) is activated by pressing the switch on the climate control module (CCM) (3/112). The climate control module (CCM) transmits the data via the Control area network (CAN) to the central electronic module (CEM) (4/56). The central electronic module (CEM) checks that the conditions to start the demist have been met. If the conditions are met, a request is transmitted via the controller area network (CAN) to the rear electronic module (REM) (4/58) to activate the relay. The rear electronic module (REM) powers the relay and the demister is powered.

The central electronic module (CEM) also transmits a request via the Control area network (CAN) back to the climate control module (CCM) to light the LED in the switch.

CARGO COMPARTMENT LIGHTING)

Fig. 205: Cargo Compartment Lighting Modules
Courtesy of VOLVO CARS CORPORATION

The cargo compartment lighting is activated when the trunk lid is opened. The central electronic module (CEM) (4/56) receives a signal from the lock (3/78) in the trunk lid. The central electronic module (CEM) transmits the information via the Controller area network (CAN) to the rear electronic module (REM) (4/58) about the status of the trunk lid. A request for cargo compartment lighting is also sent from the upper electronic module (UEM) (4/70) to the rear electronic module (REM). The lamps (10/173 (XC90)) are then powered directly from the rear electronic module (REM).

For the XC90, the roof lamp in the cargo compartment also lights..

REAR 12V SOCKET

Fig. 206: Identifying Rear 12V Socket Communication Links & Components
Courtesy of VOLVO CARS CORPORATION

When a power consuming component is connected to the rear 12V socket (17/19), the power consumption is measured via a shunt inside the rear electronic module (REM) (4/58). The rear electronic module (REM) transmits status data via the controller area network (CAN) to the driver information module (DIM) (5/1) which displays a text message.

The text message is also displayed if a power consuming component is connected when changing from ignition position:

- II to I
- I to 0 and
- 0 to the key is removed.

There is also an audible warning note when the key is removed.

PARKING ASSISTANCE SYSTEM (OPTIONAL EXTRA)

Fig. 207: Identifying Parking Assistance System Communication Links & Components
Courtesy of VOLVO CARS CORPORATION

The parking assistance system warns the drivers of close objects when reversing.

The driver is warned by a sound signal from the loudspeakers for the audio module (AUM) (16/1). The signal is transmitted via the infotainment control module (ICM) (16/94).

The rear sensors (7/131, 7/132, 7/133 and 7/134) are active when the ignition is on in position II and back-up gear (R) is selected. The sensors are deactivated automatically when the gear selector lever is moved from R to any other position. The sensors detect objects at a distance of 1.5 meters. A beeping sound is heard from the rear right-hand loudspeaker (16/5). The sound signal becomes more frequent as the distance to the object reduces. The sound is constant at distances below approximately 30 cm.

The front sensors (7/204, 7/205, 7/206 and 7/207) (option) are active when the ignition is on in position II and gear R is selected, or when the ignition is on in position II and the car is driven forwards at speeds below 10 km/h. The sensors are automatically deactivated when the car is driven forwards at above 15 km/h. On cars with automatic transmissions, the sensors are deactivated if P is selected, irrespective of speed. The sensors detect objects at a distance of 0.8 meters. A beeping sound is heard from one of the front loudspeaker on the driver's side (16/4). The sound signal becomes more frequent as the distance to the object reduces. The sound is constant at distances below approximately 30 cm.

A signal is transmitted from the parking assistance module (PAM) (4/86) to the rear electronic module (REM) (4/58). This indicates whether the buzzer should be switched on or off.

The rear electronic module (REM) then transmits a signal to the audio module (AUM) on the controller area network (CAN). This signal is sent to the Infotainment Control Module (ICM).

If a trailer or caravan is connected, the parking assistance system must be deactivated. This is done using the switch on the climate control module (CCM) (3/112).

The climate control module (CCM) then transmits a signal to the rear electronic module (REM) via the controller area network (CAN). The parking assistance system is deactivated.

TOW HITCH (OPTIONAL EXTRA)

Fig. 208: Identifying Tow Hitch Communication Links & Components
Courtesy of VOLVO CARS CORPORATION

The trailer module (TRM) (4/110) ensures that the correct type of signals are transmitted to the tow hitch cable harness.

The rear electronic module (REM) (4/58) receives messages on the controller area network (CAN) from the central electronic module (CEM) (4/56) about when output signals to the turn signal lamps, parking lamps, back-up lamps and fog lamps should be activated. The rear electronic module (REM) then transmits a direct signal to the trailer module (TRM).

The trailer module (TRM) forwards the signal to the tow hitch cable harness.

The +12 V output signal is activated when the ignition key is turned from position 0 to I, II or III. The rear electronic module (REM) transmits the signal.

+12 V supply is direct from the battery.

The rear electronic module (REM) transmits messages on the controller area network (CAN) to the central electronic module (CEM) and driver information module (DIM) (5/1), if a trailer is connected to the tow hitch connector socket. A separate indicator lamp in the driver information module (DIM) indicates when the turn signal lamps are used and the trailer is connected. If one of the turn signal lamp bulbs is defective the separate indicator lamp will not light.

The output signals for back-up lamps, fog lamps and +12 V in the socket for the tow hitch connector are market dependent. The socket for the tow hitch connector is available in a number of variants with different numbers of pins.

REAR WINDOW LIFT MECHANISMS

Fig. 209: Identifying Rear Window Lift Mechanism(s) Communication Links & Components
Courtesy of VOLVO CARS CORPORATION

The rear window lift mechanisms are operated using switches (3/85-86) in the door panels.

When the window lift mechanisms are operated from the driver's position, data is transmitted from the driver's door module (3/126) via the controller area network (CAN) to the rear electronic module (REM) (4/58) which transmits a signal to the correct relay.

There is a switch in the driver's door module (DDM) to allow for child locking, where the windows can only be operated from the driver's position. When the function is active, information is transmitted via the controller area network (CAN) to the rear electronic module (REM) to disconnect the relay. The circuit for the rear switch is then broken.

When the child lock is activated, the lighting in the rear switches goes out.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 210: Locating Rear Electronic Module (REM)
Courtesy of VOLVO CARS CORPORATION

The rear electronic module (REM) handles functions for:

- alarm (certain functions)
- locks (certain functions)
- Inclination Sensor Module alarm
- siren (XC90 structure week 201128-)
- headlamp range adjustment position sensors (Bi-Xenon)
- fuel level (Bi-fuel)
- shut-off valve (Bi-fuel)
- rear fog lamps
- back-up lamp
- stop lamps
- high level stop lamp
- rear windshield wiper/washers
- rear demist
- cargo compartment lighting
- rear 12 V socket
- parking assistance system
- electrical connections on the tow hitch
- rear parking lamps/license plate lighting
- rear window lift mechanisms.

The control module is installed as a separate unit in the rear relay box. This is under the left-hand cargo compartment panel.

The rear electronic module (REM) communicates with components which are directly connected and also with other control modules and components via serial communication and the control area network (CAN).

The control module checks activations and input and output signals using an integrated diagnostic system A diagnostic trouble code (DTC) is stored if the control module detects an error. In certain cases the control module replaces the faulty signal with a substitute value.

Any diagnostic trouble codes (DTCs) are stored in the control module memory. This information can be read off using VIDA via the data link connector in the vehicle.

Lock and unlock the rear doors to check whether the rear electronic module (REM) is grounded and powered. The control module is powered and grounded if the doors lock and unlock. Another way to check whether the rear electronic module (REM) is powered and grounded is to switch on the rear fog lamp.

SIGNALS

The following table summarizes input signals to and output signals from the rear electronic module (REM). The signal types are divided into directly connected signals, serial communication and controller area network (CAN) communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: • Fuel level sensor (CNG) (7/156) • Fuel level sensor (LPG) (7/153) • Stop lamps from the central electronic module (CEM) (4/56) • Position sensor for headlamp range adjustment (Bi-Xenon) (7/120) • Tailgate lock unit (3/78) • Trailer module (TRM) (4/110) (optional extra).	**Directly connected:** • Fuel level sensor (CNG) (7/156) • Rear demist, relay (9/2) • Cargo compartment lighting (10/127-128, 10/173) (S60/S80/XC90) • High level stop lamp (10/19) • Position sensor for headlamp range adjustment (Bi-Xenon) (7/120) • Inclination sensor module (ISM) (7/100) (XC90 structure week -201127) • Trailer module (TRM) (4/110) (optional extra).
Via serial communication: • Inclination sensor module (ISM) (7/100) (extra equipment) (XC90 structure week -201127) • Inclination sensor module BBS-IS (16/35) (extra equipment) (XC90 structure week 201128-) • Siren BBS (16/35) (extra equipment) (XC90 structure week 201128-) • Parking assistance module (PAM) (4/86) (optional extra).	**Via serial communication:** • Inclination sensor module (ISM) (7/100) (extra equipment) (XC90 structure week -201127) • Inclination sensor module BBS-IS (16/35) (extra equipment) (XC90 structure week 201128-) • Siren BBS (16/35) (extra equipment) (XC90 structure week 201128-) • Parking assistance module (PAM) (4/86) (optional extra).
Via Controller Area Network (CAN) communication:	**Via Controller Area Network (CAN) communication:**

• Climate Control Module (CCM) (3/112) • Central electronic module (CEM) (4/56) • Engine control module (ECM) (4/46) • Supplemental Restraint System Module (SRS) (4/9) • Upper electronic module (UEM) (4/70) • Driver door module (DDM) (3/126).	• Climate Control Module (CCM) (3/112) • Central electronic module (CEM) (4/56) • Driver information module (DIM) (5/1) • Infotainment control module (ICM) (16/94) (XC90) • Phone module (PHM) (16/60) (optional equipment) • Supplemental Restraint System Module (SRS) (4/9) • Transmission control module (TCM) (4/28).

REAR SEAT ENTERTAINMENT SYSTEM (RSE), GENERATION 3.1/3.2 (2005-2006)

DESIGN

REAR SEAT ENTERTAINMENT MODULE (RSE)

Fig. 212: Rear Seat Entertainment Module (RSE)
Courtesy of VOLVO CARS CORPORATION

The rear seat entertainment module (RSE) is enclosed in a steel casing with installation holes. In the XC90, it is located below the centre console between the driver's and passenger seat. The control module is driven from Ext. X-feed in the central electronic module (CEM).

The central unit of the rear seat entertainment system is the rear seat entertainment module (RSE), which interprets and implements the commands issued by the user via the system's infrared remote control. These commands are forwarded to the rear seat entertainment module (RSE) via the system's infrared receiver in the screens. The rear seat entertainment system (RSE) also distributes current to the system and detects the status of the vehicle ignition via a sensor lead that runs from the control module to the vehicle ignition switch. This prevents battery consumption when the vehicle is not in use.

The rear seat entertainment module (RSE) receives audio and video signals from the DVD player and the vehicle's TV receiver (if installed). It is also possible to receive additional input audio/video and output a two-channel audio output at low level via the AUX inputs.

REAR AUDIO SEPARATION MODULE (RAS)

Fig. 213: Rear Audio Separation Module (RAS)
Courtesy of VOLVO CARS CORPORATION

The rear audio separation module (RAS) is enclosed in a casing of ribbed aluminium with installation holes.

The rear audio separation module is a unit with dual functions. The first is the production of continual infrared signals via "control module infrared transfer" for "wireless headphones" (audio is in headphone mode as standard). The second is integration with the vehicle's rear speakers for media selection.

SCREEN, HEAD RESTRAINT

Fig. 214: Screen, Head Restraint
Courtesy of VOLVO CARS CORPORATION

The multimedia head restraint consists of five main components:

- Screen
- Circuit board
- Rear piece
- Border
- Head restraint pad

The rear piece is fastened in an opening on the rear of the head restraint pad. The circuit board is held in place

in the rear piece with three screws. The screen is housed in the rear piece in front of the circuit board and is connected with a flexible foil cable and an AC lead. The border holds all electronic components in place in the rear piece in the head restraint pad. The lower edge of the border contains a window so that the infrared receiver on the circuit board can receive infrared signals from the remote control. The infrared receiver is separately connected to the rear seat entertainment module (RSE) and is activated when the rear seat entertainment module (RSE) is on.

The 7-inch screen has an aspect ratio of 16:9. The screen is positioned to provide the optimal viewing angle. The screen has a 120 degree horizontal viewing angle.

The integrated infrared receiver is activated when the rear seat entertainment module (RSE) is supplied power. The screen is activated once the receiver obtains an infrared "switch-on command" from the remote control. The circuit board contains an image generator, an infrared receiver and a unit that controls all screen settings:

- colour
- contrast
- brightness
- aspect ratio.

Contrast control has a contrast ratio of 30:1 to improve the image and reduce sharp light from bright daytime conditions down to complete darkness. Brightness can be adjusted so that the image on the screen is clear even in daylight. The circuit board is also responsible for voltage protective and the power supply to the screen's background illumination. The control module contains logic for interpreting commands for setting video output, input selections and background illumination brightness.

The screens are supplied power and grounded via the rear seat entertainment module (RSE).

DVD PLAYER

Fig. 215: Identifying DVD Player
Courtesy of VOLVO CARS CORPORATION

The DVD player has a compact chassis and border in miniature format that is ideal for tight installation locations (148 mm x 55 mm x 160 mm). The DVD player has standard ISO connections. Its mechanism is resistant to vibrations and works to avoid the image or audio becoming choppy during playback. The DVD

player has slot-in disc feed with region coding programmed into the software. The DVD player has video output in NTSC or PAL format depending on the format of the DVD disc. The player is completely integrated with the rear seat entertainment system and is controlled with the infrared remote control via the rear seat entertainment module (RSE). The operating temperature of the player is -20 to +70 °C.

Introduction of a new DVD player is planned for week 5 2005. The new and improved DVD player can read DVD-R/+R, DVD-RW/+RW, CD-R and CD-RW discs and can play MP3 files. The "+" and "-" buttons can now be used to change chapters in a DVD movie or jump to the next track on a CD.

The DVD player is supplied power and grounded via the rear seat entertainment module (RSE).

HEADPHONES

Fig. 216: Identifying Headphones
Courtesy of VOLVO CARS CORPORATION

The wireless IR headphones are compatible with both screens. IR transfer is used to transfer standard audio to the headphones in two-channel stereo format. The headphones are powered by internal batteries. The headphones are switched on with a button on one side while the volume of the respective headphones is adjusted with a wheel. Each set also has a channel selector that controls which audio source the set of headphones receives.

EXTERNAL INPUT

Fig. 217: External Input
Courtesy of VOLVO CARS CORPORATION

The rear of the centre console (XC90) houses an AUX panel with external input connections for audio/video. This input can be used for inputting standard AV signals to the system. Such signals include video camera, Dreamcast, Nintendo, Playstation, Playstation 2, VHS videotapes, portable DVD or CD player.

DIAGNOSTIC FUNCTIONS

The rear seat entertainment system is not connected to the vehicle's CAN network and contains no diagnostic trouble codes or readable diagnostic services. System fault tracing is done via symptom input.

FUNCTION

REAR SEAT ENTERTAINMENT MODULE (RSE)

Fig. 218: Rear Seat Entertainment Module (RSE)
Courtesy of VOLVO CARS CORPORATION

The rear seat entertainment system is supplied power and regulated by the rear seat entertainment module (RSE) (16/124).

When the rear seat entertainment module (RSE) receives a switch-on command from the infrared remote control via the IR receivers in one of the head restraints, it performs a simple system check and then sends commands to other system components for activation. Once a screen (16/81A, B) has been selected with the infrared remote control, the rear seat entertainment module (RSE) identifies the selected screen and displays a menu from which the user can select the functions described below:

- Independent shifting of three audio/video inputs (DVD, TV (if installed) and AUX)
- Image adjustment (image colour, brightness, contrast and aspect ratio)
- Audio settings (bass, treble and volume)
- Language selection for on-screen instructions
- Switch individual screens ON/OFF

The rear seat entertainment module (RSE) also determines which media source has been linked to the selected screen and forwards the commands in an appropriate protocol. For example, if screen 1 is set for DVD playback and an infrared playback command is detected at screen 1, it will be received, stored and forwarded to the DVD player (16/82) in the DVD player's infrared protocol. A fixed memory stores the instruction language used and current audio and video settings for the respective output channel. These settings are loaded upon start. Volume

is automatically set to low level.

REAR AUDIO SEPARATION MODULE (RAS)

Fig. 219: Rear Audio Separation Module (RAS)
Courtesy of VOLVO CARS CORPORATION

The rear audio separation module (RAS) (16/122) is a unit with dual functions. The first is the production of continual infrared signals for the wireless headphones (audio is in headphone mode as standard) via the IR transmitter (16/125). The second is integration with the vehicle's rear speakers 16/5, 16/6, 16/57, 16/58 (XC90)) for media selection.

When the unit is in standard mode, audio signals are sent from the front audio system to the rear speakers. When selected using the remote control, the rear audio separation module (RAS) is activated and audio signals from the front audio system are replaced with audio signals from the rear seat entertainment system. In rear seat entertainment system mode, media signals for the right or left screen can be selected via the remote control.

NOTE: **Lowering the volume of the screen will increase the signal/noise ratio of the headphones. Optimal headphone output is obtained by setting screen volume to 75%. Headphone volume can then be set on the headphones themselves.**

INFRARED (IR) CONTROL

Fig. 220: Infrared (IR) Control
Courtesy of VOLVO CARS CORPORATION

Each screen houses an IR receiver. The IR receivers are connected to the rear seat entertainment module (RSE) (16/124) and are activated when the rear seat entertainment module (RSE) is supplied power. When a button is pressed on the remote control, it emits a signal with infrared light. The coding of this signal varies depending on which button was pressed. The IR signal is received by the IR receiver below the respective head restraint screen (16/81A, B) and is forwarded to the rear seat entertainment module (RSE) for processing.

The remote control can be used to switch between different audio and/or video inputs in the system:

- DVD player, audio/video
- AUX input, audio or audio/video
- Audio from the front audio system to one of the headphones, both headphones or separately to one of the headphones and the rear speakers
- Audio/video from a TV receiver (if installed) to one or both screens.

The remote control is used for selection by aiming it at the screen that is to respond to the command. The command from the remote control is received by one (or both) of the IR receivers located below the screens (16/81A, B). The integrated infrared receiver is activated when the rear seat entertainment module (RSE) (16/124) is supplied power. The receiver forwards the command to the rear seat entertainment module (RSE). The rear seat entertainment module (RSE) will select AV or audio source for the screen in question. The remote control can then be aimed at the other screen to select a source for that screen.

DVD PLAYER

Fig. 221: DVD Player
Courtesy of VOLVO CARS CORPORATION

NOTE: There may be a slight delay between selecting a DVD function with the remote control and activation of the DVD player function. A message will appear on the screen to confirm that the DVD function was selected. Display of "Not permitted" indicates that the DVD player is still processing a previously selected function.

The DVD player is not operational until the rear seat entertainment module (RSE) (16/124) has been activated via an infrared switch-on command from the remote control and the screens are lit.

NOTE: This means, for example, that a disc in the DVD player (16/82) cannot be ejected until the rear seat entertainment system has been switched on.

A microprocessor is used to control the power supply to the DVD player based on the position of the ignition key. This is handled via a connection from the ignition switch to the rear seat entertainment system (RSE). The system is functional when the ignition key is in position II. If the voltage in the lead is high, the DVD player can be supplied power. If voltage in the lead is low, the system cannot be supplied power. The lead for controlling power supply is also used to activate the fan on the rear of the player.

The microprocessor is also used to send commands to and receive information from the DVD mechanism. IR commands from the remote control are received by the rear seat entertainment module (RSE) and come to the DVD player via the IR pin on the rear connection block (ISO connection). IR commands are interpreted by the microprocessor. The DVD player is used to read the source media, which consists of DVDs and CDs that fulfil relevant standards. The DVD player does not read CD-R discs. The use of DVD-R, CD-RW and DVD-RW discs in the DVD player is also discouraged.

NOTE: Introduction of a new version of the DVD player is expected week 5 2005. The new DVD player can play DVD-R/+R, DVD-RW/+RW, CD-R and CD-RW discs. It can also read Kodak photo CDs and play MP3 files in the disc's root directory and subfolders. The DVD player will also be able to read play lists for MP3 files in M3U format.

When a DVD is inserted in the opening, DVD playback starts automatically if the disc does not have a play

menu. DVD playback can be resumed from a pause, for example if the ignition is switched off while a movie is being played. Playback then resumes where it left off once the ignition is switched back on. Audio and video signals are fed out from the DVD player from the connection block (ISO connection) on the rear of the unit.

HEADPHONES

Fig. 222: Headphones
Courtesy of VOLVO CARS CORPORATION

Two sets of IR headphones are included. Any number of headphones can be used provided they are within the area of the IR transmitter. The wireless headphones use an infrared signal. There must be a free path between the transmitter and the receivers on the side of the headphones. If the path is blocked, audio will be interrupted. The headphones are activated by pressing the power button on one side of the headphones. They switch off automatically 3-4 minutes after the IR transmitter has stopped sending a signal.

NOTE: Lowering the volume of the screen will increase the signal/noise ratio of the headphones. Optimal headphone output is obtained by setting screen volume to 75%. Headphone volume can then be regulated using the wheel on the headphones themselves.

IDENTIFICATION OF GENERATION

REAR SEAT ENTERTAINMENT SYSTEM

NOTE: This information does not apply to roof mounted systems.

Rear seat entertainment systems are available in a number of different generations. The generations have different designs and are equipped with different functions. This section describes the easiest method to identify which generation of system is installed in the vehicle.

The table below shows which generations are available for each model and model year. This is followed by the most distinct differences between the generations.

The information in the table only applies to factory installed systems. To identify a retrofitted accessory system, see each generation below.

Model	Model year	Remarks	Generation
S80 (-06)	2002-2005	For chassis number: 257332-431446	3.1
	2005-2006	For chassis number: 431447-446475	3.2
XC90	2005-2006	For chassis number: 137372-258728	3.2
	2006-2007	For chassis number: 258729-371137	4.1
	2007-2008	For chassis number: 371138-*	4.2
	2009-		4.3
V70 (00-08)	2006-2008		4.1
V70XC (01-)/XC70 (-07)	2006-2007		4.1
S80 (07-)	2007-2008		4.2
	2009-		4.3
V70 (08-)/XC70 (08-)	2008		4.2
	2009-		4.3

* Until model year 2008 changed to model year 2009.

Fig. 223: Identifying Remote Control (Generation 3.1)
Courtesy of VOLVO CARS CORPORATION

Generation 3.1

Equipped with a remote control that has 29 buttons.

Has two 7" screens.

NOTE: **When replacing the Rear seat entertainment module (RSE) the remote control must also be replaced. The new remote control, which must be used, is generation 3.2. The chassis number as set out above must now be used to distinguish the systems.**

Fig. 224: Identifying Remote Control (Generation 3.2)
Courtesy of VOLVO CARS CORPORATION

Generation 3.2

Equipped with a remote control that has 16 buttons.

Has two 7" screens.

Fig. 225: Identifying Remote Control (Generation 4.1)
Courtesy of VOLVO CARS CORPORATION

Generation 4.1

Is equipped a remote-control that has 22 buttons of which one button is red and 21 are white.

In addition, there are two sockets for headphones on the AUX panel. One socket for the left-hand screen and one socket for the right-hand screen.

Has two 7" screens.

Fig. 226: Identifying Remote Control (Generation 4.2)
Courtesy of VOLVO CARS CORPORATION

Generation 4.2

Is equipped a remote-control that has 22 buttons of which one button is red and 21 are white.

Has two 7" screens.

Fig. 227: Identifying Remote Control (Generation 4.3)
Courtesy of VOLVO CARS CORPORATION

Generation 4.3

Equipped with a remote control that has 17 buttons.

If the system is equipped with a TV (DVB-T) the remote control has 29 buttons. In addition, there is a visible card slot for a subscription/program card on the TV receiver.

The TV receiver is installed in the cargo compartment, in XC90 on the right-hand side under the cover above the wheel housing.

Has two 8" screens.

SYSTEM OVERVIEW

REAR SEAT ENTERTAINMENT SYSTEM

The rear seat entertainment system is a mobile entertainment system specially designed to keep rear seat passengers occupied and entertained with video games or movies.

The system is completely integrated in the vehicle, with two separately controlled high resolution 7-inch screens designed to resist any adverse condition to which they can be subjected during the journey. The screens are mounted in the head restraints.

The rear seat entertainment module (RSE) can receive up to three AV inputs and can output video to two separately controlled screens.

A connection panel with AV inputs is mounted on the rear of the centre console.

Audio is sent out to the component headphones via an IR transmitter or to the vehicle's rear speakers.

The system is controlled via an infrared remote control, which can also be used to control the DVD player and the vehicle's front audio system (if installed).

NOTE: **The DVD player is not operational unless the rear seat entertainment system is on. This means, for example, that a DVD disc cannot be ejected from the player unless the rear seat entertainment system has been switched on using the remote control.**

Fig. 228: Rear Seat Entertainment System -- System Overview
Courtesy of VOLVO CARS CORPORATION

1. Screen, head restraint (16/81A, B)
2. DVD player, rear (16/82)
3. Rear seat entertainment module (RSE) (16/124)
4. Rear audio separation module (RAS) (16/122)
5. Fuse holder (11F)
6. Infrared transmitter (16/125)
7. AUX socket (16/123)

SIGNALS

The tables below summarise the input and output signals to the units of the rear entertainment system. The signal type is only directly connected signals as the rear seat entertainment module (RSE) is not connected to the CAN network.

REAR SEAT ENTERTAINMENT MODULE (RSE) (16/124)

Input signals	Output signals
Direct connection: • Commands from remote control via head	**Via infrared - direct connection:** • Command to DVD player (16/82)

restraint screens (16/81A, B) • Audio/video signals from DVD player (16/82) • Audio/video signals from AUX panel (16/123)	forwarded from remote control • Audio to rear audio separation module (RAS) (16/122)
-	**Serial communication:** • Head restraint screens (16/81A, B)

REAR AUDIO SEPARATION MODULE (RAS) (16/122)

Input signals	Output signals
Audio (Tri-Level) - direct connection: • Rear seat entertainment module (RSE) (16/124) for controlling audio path between headphones/rear speakers	**Direct connection:** • Rear speakers (16/17, 16/18 (S80)), (16/5, 16/6, 16/57, 16/58 (XC90)) • IR transmitter (16/125) (signal to headphones)
Audio - direct connection: • Rear seat entertainment module (RSE) (16/124)	-

SCREEN, HEAD RESTRAINT (16/81A, B)

Input signals	Output signals
Wireless communication (IR): • Remote control.	-
-	**Direct connection:** • Rear seat entertainment module (RSE) (16/124), forwarded commands from remote control
Serial communication: • Rear seat entertainment module (RSE) (16/124), video signals.	-

DVD PLAYER, REAR (16/82)

Input signals	Output signals
Direct connection: • IR commands from remote control forwarded via rear seat entertainment module (RSE) (16/124)	**Output signals** • Audio/video signals to rear seat entertainment module (RSE) (16/124)

INFRARED HEADPHONES

Input signals	Output signals

Wireless (IR): • IR transmitter (16/125)	-

REAR SEAT ENTERTAINMENT SYSTEM (RSE), GENERATION 3.1/3.2 (EXECUTIVE; PREMIER; 2004)

DESIGN

IDENTIFICATION OF GENERATION

see **IDENTIFICATION OF GENERATION**

SYSTEM OVERVIEW

see **SYSTEM OVERVIEW**

REAR SEAT ENTERTAINMENT SYSTEM (RSE), GENERATION 4.1 (2006-2007)

DESIGN

REAR SEAT ENTERTAINMENT MODULE (RSE)/DVD PLAYER

Fig. 229: Identifying DVD Player
Courtesy of VOLVO CARS CORPORATION

Rear seat entertainment module (RSE) is the central unit in the system for rear seat entertainment.

The control module is integrated with the DVD player and is located at the rear edge of the center console.

The control module interprets and carries out the commands given by the user using the system's infra red remote control. These commands are then forwarded from the remote control to the Rear seat entertainment module (RSE) via the system's infra red receiver in the screens. The Rear seat entertainment module also distributes current to the system's other components.

The Rear seat entertainment module distributes audio and video signals from the DVD player to screens and loudspeakers in the system. Other audio and video sources can be connected via external inputs, such as games consoles and video cameras etc.

The DVD player mechanism has an anti-shock system and it helps to prevent the image or sound skipping when played. The DVD player has slot-in disc insertion and region coding programmed into the software. The region code can be changed using a security code.

The following media formats can be played by the DVD player:

- DVD-R/+R
- DVD-RW/+RW
- CD-R and CD-RW
- CDDA
- HDCD

The following information formats can be played:

- DVD
- DVD Audio
- VCD
- SVCD
- DivX
- WMV
- Audio CD
- Kodak photo CD
- MP3
- MP3 Pro
- playlists in M3U format
- WMA Sound.

Formats such as THX and DolbyDigital are also supported. Only stereo signals of this audio format are reproduced.

The control module is supplied with power from the Ext. X-supply in the Central electronic module and directly from the battery.

To easily check whether the control module is powered and grounded, switch on the ignition. The background illumination on the function buttons should then come on.

Change of DVD player region code

The region coding means that only discs with the region code matching that of the DVD player can be played.

The region code in the DVD player can be changed up to 10 times. After the 11th change, the set region will then be locked and it will not be possible to change again.

NOTE: Warranty repairs due to locked region on the DVD player will not be approved. Region code changes to the region in which the vehicle will be used is to be done at the workshop. The security code is not to be given to the customer.

Do as follows to open the menu for region code change:

Model year 2006:

1. Switch on the system
2. Open the menu:
3. Enter the code: 1971 and press

Model year 2007-:

1. Switch on the system

   NOTE: There must not be a disc in the DVD player.

2. Aim the remote control at a screen and depress the button for child lock for approx. 5 seconds. The menu will be displayed with four stars underneath.
3. Enter the code 1971 using the arrow keys on the remote control and then press OK.
4. Select menu selection and press OK.

The submenu can then be used to select a new region for the DVD player.

REAR AUDIO SEPARATION MODULE (RAS)

Fig. 230: Identifying Rear Audio Separation Module (RAS)
Courtesy of VOLVO CARS CORPORATION

The rear audio separation module (RAS) is enclosed in a ribbed aluminum casing with installation holes.

The task of the Rear audio separation module (RAS) is to distribute audio from various audio sources to the vehicle's rear loudspeakers.

The Rear audio separation module (RAS) is supplied with power from the Rear seat entertainment module (RSE).

To check whether the rear audio separation module (RAS) is powered and grounded, switch on the ignition and then switch on the rear seat entertainment system.

You must then use the remote control to activate the sound to the rear speakers.

When the function is activated, there is an audible click from an internal relay in the rear audio separation module (RAS).

SCREEN, HEAD RESTRAINT

Fig. 231: Identifying Rear Facing Head Restraint Video Screen
Courtesy of VOLVO CARS CORPORATION

The multimedia head restraint consists of five main components:

- Screen
- Circuit board
- Rear piece
- Border
- Head restraint pad

The rear piece is fastened in an opening on the rear of the head restraint pad. The circuit board is held in place in the rear piece with three screws. The screen is housed in the rear piece in front of the circuit board and is connected with a flexible foil cable and an AC lead. The border holds all electronic components in place in the rear piece in the head restraint pad. The lower edge of the border contains a window so that the infrared receiver on the circuit board can receive infrared signals from the remote control. The infrared receiver is separately connected to the rear seat entertainment module (RSE) and is activated when the rear seat entertainment module (RSE) is on.

The 7-inch screen in the head restraint has an aspect ratio of 16:9. The screen is positioned to provide the optimal viewing angle. The screen has a 120 degree horizontal viewing angle.

The integrated infrared receiver is activated when the rear seat entertainment module (RSE) is supplied power. The screen is not activated until it receives a high signal from the rear seat entertainment module (RSE)/DVD player via the wake-up cable.

This signal is sent when the system is switched on with the POWER button on the remote control or with the POWER button on the control module.

The circuit board contains an image generator, infrared receiver, infrared transmitter and the unit that controls all screen settings:

- colour
- contrast
- brightness
- aspect ratio.

The damping control has a damping ratio of 30:1 to improve the image and reduce bright light from daylight conditions down to complete darkness. Brightness can be adjusted so that the screen's image can easily be seen in daylight. Voltage protection and current supply of the background lighting also occurs via the circuit card. The control module contains logic for interpreting the command for setting the video performance, input selection and strength of background lighting. The control command is transmitted from the Rear seat entertainment module (RSE) via a private CAN network.

Each screen has an integrated infrared transmitter to send audio signals to the supplied wireless headphones. On the AUX panel, on the rear of the center console there is also an output for connecting headphones with leads.

The screens are supplied power and grounded via the rear seat entertainment module (RSE).

To check whether a screen has power and ground, you can switch on the ignition and then switch on the system with the remote control. The screen will then come on.

NOTE: **If there is power and ground to the screen, but the screen does not have contact with the rear seat entertainment module (RSE)/DVD player, the screen will come on in LOCAL mode nonetheless. This is no guarantee that the entire system is operational.**

If the screen works in LOCAL mode this indicates that the voltage supply and ground to the screen's circuit board are OK.

REMOTE CONTROL

Fig. 232: Identifying Remote Control
Courtesy of VOLVO CARS CORPORATION

The remote control is used to control the Rear seat entertainment module (RSE)/DVD player and the screens.

The remote control has 22 buttons; 1 red button and 21 white buttons.

The remote control uses infrared signals (IR) to transfer commands to the system. The signals are received by the screens' infrared receivers.

The remote control is equipped with two batteries, fitted under a cover at the rear.

HEADPHONES

Fig. 233: Identifying Headphones
Courtesy of VOLVO CARS CORPORATION

The wireless IR headphones can be used with both screens. IR transfer is used to transfer standard audio to the headphones in two-channel stereo format. The headphones are powered by internal batteries. The headphones are switched on with a button on one side while the volume of the respective headphones is adjusted with a wheel. Each set also has a channel selector that controls which audio source the set of headphones receives.

The audio from the left screen is always transmitted on channel A and the audio from the right screen is always transmitted on channel B.

EXTERNAL INPUT (AUX)

Fig. 234: Identifying AUX Panel
Courtesy of VOLVO CARS CORPORATION

On the rear of the center console there is an AUX panel with external input terminals for audio/video. This input can be used for supplying standard AV signals to systems, such as, video cameras, video game consoles, VHS videos, portable DVD or CD players.

All inputs on the AUX panel are directly connected to the rear seat entertainment module (RSE)/DVD player.

Two headphone sockets for connecting headphones with wires are also on the panel, one for the left-hand screen and one for the right-hand screen.

DIAGNOSTIC FUNCTIONS

FAULT-TRACING INFORMATION

The rear seat entertainment module (RSE)/DVD player does not have any diagnostic functions and is not connected to the rest of the car's CAN network. Because of this, for example, no diagnostic trouble codes can be read from the control module. **All fault tracing must be done by fault tracing symptoms**

The following is information that may facilitate when fault tracing in the system.

When the ignition is switched on the Rear seat entertainment module (RSE) performs a basic internal system check and starts the start-up procedure with the screens.

If the time from when the ignition is switched on until the system is in standby mode (only the illuminated POWER button is lit) is longer than normal or that the lighting does not appear to be normal, this indicates a communication fault with the screens.

The start-up times, see: **SYSTEM START-UP**

A long start-up time or irregularities can be due to:

- No supply voltage and ground to the screen
- Damaged wake-up signal cable.
- Damaged leads for the internal CAN-network (no communication can take place). In connector D on Rear seat entertainment module (RSE)/DVD-player, which contains the connections to the control module for rear audio separation (RAS), there is a bridging of the CAN-net for *right screen* .

  Bridging is there so that in the future the system can be extended with additional units. If connector D has been damaged, has slipped out, or if there for some reason is no contact between the ends on the bridging of the CAN-leads, it will not be possible to establish communication.

Switch on the system using the remote control

If the system is switched on using the remote control aimed towards the right-hand screen, when the voltage supply and ground to the screen are fully functional but for example there is no CAN-communication with the Rear seat entertainment module (RSE)/DVD-player, the screen will be lit and work in LOCAL mode. It will then be possible to show the menus and to adjust the sound and brightness settings.

This can be misinterpreted as the function is OK. However no image will be shown on screen if, for example, you play a DVD disc. The system will be switched on and the left-hand screen will start. This is because the cables for the IR signals do not go via the CAN network, but go directly to the DVD player and are interpreted.

If the screen works in LOCAL mode this indicates that the voltage supply and ground to the screen's circuit board are OK.

Later software

Switch on the system using the POWER button on the DVD player

If one of the screens does not start when the system is switched on, when the start-up procedure has elapsed over the normal time (without fault), and only the POWER lamp on the control module/DVD player is lit, this indicates a fault with the actual screen or the cables between the screen and the circuit board.

When communication with the control modules/DVD player in this case is okay, both these screens' circuit boards behind the actual screens are OK.

The functionality of the circuit boards can also be checked by switch on the system and checking whether the IR lamps in the bottom of the screen are slightly illuminated.

The IR-lights are lit for about 2 minutes after the system is switched on or when sound is played from a selected audio source.

FUNCTION

REAR SEAT ENTERTAINMENT MODULE (RSE)

Fig. 235: Identifying Rear Seat Entertainment Module Communication Links & Components
Courtesy of VOLVO CARS CORPORATION

NOTE: There may be a slight delay between selecting a DVD function with the remote

control and activation of the DVD player function. A message will appear on the screen to confirm that the DVD function was selected. Display of indicates that the DVD player is still processing a previously selected function.

The rear seat entertainment system is supplied with power and regulated by the rear seat entertainment module (RSE) (16/82).

The control module also includes the DVD player for the system.

The system can either be switched on with the POWER button on the control module or with the POWER button on the remote control.

The remote control must be aimed at one of the screens before a button is depressed as the receiver for remote control signals is located in the bottom edge of the screens.

When the remote control is aimed at a screen (16/81A, B) and a function button is depressed, the rear seat entertainment module (RSE) identifies the selected screen and carries out the remote control command.

If, for example, you press a menu selection button, a menu opens on the screen at which the remote control was aimed. The possible selections are described below:

- Independent shifting of three audio/video inputs (DVD, TV (if installed) and AUX).
- Image adjustment (image color, brightness, contrast and aspect ratio).
- Audio settings (bass, treble and volume).
- Language selection for on-screen instructions.
- Switch individual screens ON/OFF.

The rear seat entertainment module (RSE) also determines which media source has been linked to the selected screen and forwards the commands in the suitable protocol.

If, for example, the left screen is set for DVD playback and an infrared play command is detected at the left screen, the message is received, saved and forwarded to the DVD player (16/82) in the DVD player's infrared protocol.

A fixed memory saves the displayed instruction language used and the current audio and video settings for the respective output channel. These settings are loaded upon start-up with the exception of volume level, which is set to low as standard.

The system is powered via X-feed and directly from the battery. If the system is operating when the ignition is switched of, a question will appear on the screens as to whether continued play is permitted.

If the user answers YES, the system will continuing playing another 10 minutes. The system will then shut down. If there is no response to the question, the system will shut down after 1 minute. As a means of safeguarding the battery, play time cannot be extended unless the ignition is switched on again.

When a DVD is inserted in the opening, DVD playback starts automatically if the disc does not have a play

menu. DVD playback can be resumed from a pause, for example if the ignition is switched off while a movie is being played. Playback then resumes where it left off once the ignition is switched back on. Audio and video signals are fed out from the DVD player from the connection block (ISO connection) on the rear of the unit.

SYSTEM START-UP

When the ignition is switched on the Rear seat entertainment module (RSE) performs a basic internal system check and starts the start-up procedure with the screens.

The start-up process differs depending on software.

Previous software

Start-up process, no communication fault

1. The ignition is switched on.
2. Lighting in the DVD-player's buttons is activated.
3. The Rear seat entertainment module (RSE) feeds the connections #E1 (left-hand screen) and #E13 (right-hand screen) with voltage.
4. The Rear seat entertainment module (RSE) sends a wake-up signal of approximately 11.5 V to connection #E2 for the left-hand screen.
5. The left-hand screen then returns an OK signal to the Rear seat entertainment module (RSE) via the internal CAN network.
6. The Rear seat entertainment module (RSE) returns a message to the left-hand screen on the CAN network which assigns the screen number 1. This is necessary for the video and audio to be addressed to the right screen and so that commands from the remote control can be executed on the right screen. Wake-up signal's voltage maintained at 11.5 V.
7. Communication for the left-hand screen is now OK.
8. The Rear seat entertainment module (RSE) sends a wake-up signal of approximately 11.5 V to connection #E14 for the right-hand screen.
9. The right-hand screen then returns an OK signal to the Rear seat entertainment module (RSE) via the internal CAN network.
10. On the CAN, the Rear seat entertainment module (RSE) sends back a message to the right hand screen allocated screen number 2. The wake-up signal's voltage is maintained at 11.5 V.
11. Communication for the right-hand screen is now OK.
12. Lighting in the DVD-player's buttons, except the POWER button, goes out.
13. The start-up procedure is implemented and the system switches to standby.

Start-up times

A start-up with fault-free communication takes 4-10 seconds.

Start-up process, communication fault with left screen

1. The ignition is switched on.
2. Lighting in the DVD-player's buttons is activated.
3. The Rear seat entertainment module (RSE) feeds the connections #E1 (left-hand screen) and #E13 (right-hand screen) with voltage.
4. The Rear seat entertainment module (RSE) sends a wake-up signal of approximately 11.5 V to connection #E2 for the left-hand screen.
5. No response from left screen. The Rear seat entertainment module (RSE) maintains high voltage (11.5V), but drops it down to 0 V every 10 seconds until further notice. The wake-up signal to the right screen is 0 V.
6. Lighting in the DVD player's buttons follow the same pattern as the wake-up signal for the left screen.
7. The system will not work.

Start-up process, communication fault with right screen

1. The ignition is switched on.
2. Lighting in the DVD-player's buttons is activated.
3. The Rear seat entertainment module (RSE) feeds the connections #E1 (left-hand screen) and #E13 (right-hand screen) with voltage.
4. The Rear seat entertainment module (RSE) sends a wake-up signal of approximately 11.5 V to connection #E2 for the left-hand screen.
5. The left-hand screen then returns an OK signal to the Rear seat entertainment module (RSE) via the internal CAN network.
6. The Rear seat entertainment module (RSE) returns a message to the left-hand screen on the CAN network which assigns the screen number 1. This is necessary for the video and audio to be addressed to the right screen and so that commands from the remote control can be executed on the right screen. Wake-up signal's voltage maintained at 11.5 V.
7. Communication for the left-hand screen is now OK.
8. The Rear seat entertainment module (RSE) sends a wake-up signal of approximately 11.5 V to connection #E14 for the right-hand screen.
9. No response from right screen. The Rear seat entertainment module (RSE) maintains high voltage (11.5V), but drops it down to 0 V every 10 seconds until further notice. The wake-up signal to the left screen (whose communication is OK) is continually high (11.5V).
10. Lighting in the DVD player's buttons follow the same pattern as the wake-up signal for the right screen.
11. The system will not work.

Start-up process, CAN related fault

1. The ignition is switched on.
2. Lighting in the DVD-player's buttons is activated.
3. The Rear seat entertainment module (RSE) feeds the connections #E1 (left-hand screen) and #E13 (right-hand screen) with voltage.
4. The Rear seat entertainment module (RSE) sends a wake-up signal of 11.5 V at the same time to both

terminals, #E2 for the left screen and #E14 for the right screen.

5. The Rear seat entertainment module (RSE) maintains high voltage (11.5 V) to both screens, but drops it down to 0 V every 10 seconds until further notice.
6. Lighting in the DVD player's buttons follow the same pattern as the wake-up signal for the screens.
7. The system will not work.

Conclusions of start-up signal's voltage

By checking the wake-up signal's voltage to both the screens during system start-up, the following conclusions can be drawn. The table below is worked into the symptom fault-tracings.

Left screen	Right screen	Conclusion
Voltage is continually high (11.5 V).	Voltage is continually high (11.5 V).	Communication with both screens established and OK.
Voltage is high (11.5 V) but drops to 0 V every 10 seconds.	Voltage is 0 V.	No communication with left screen. No attempt made with right screen.
Voltage is continually high (11.5 V).	Voltage is high (11.5 V) but drops to 0 V every 10 seconds.	Communication with left screen established and OK. No communication with right screen.
Voltage is continually high (11.5 V).	Voltage is 0 V.	Communication with left screen established and OK. Probable open-circuit on wake-up signal for right screen.
Voltage is 0 V.	Voltage is 0 V.	No communication with left screen. No attempt made with right screen. Probable open-circuit on wake-up signal for left screen.
Voltage is high (11.5 V) but drops to 0 V every 10 seconds.	Voltage is high (11.5 V) but drops to 0 V every 10 seconds.	Probable fault with CAN communication with screens.

Later software

1. The ignition is switched on.
2. Lighting in the DVD-player's buttons is activated.
3. The Rear seat entertainment module (RSE) feeds the connections #E1 (left-hand screen) and #E13 (right-hand screen) with voltage.
4. The Rear seat entertainment module (RSE) sends a wake-up signal of approximately 11.5 V to connection #E2 for the left-hand screen.
5. The left-hand screen then returns an OK signal to the Rear seat entertainment module (RSE) via the internal CAN network.

NOTE: the screen does not respond on the CAN network, the Rear seat

entertainment module (RSE) makes a further two attempts according to the pattern below (*). If the screen does not respond the Rear seat entertainment module (RSE) continues as set out in section 8 below.

6. The Rear seat entertainment module (RSE) returns a message to the left-hand screen on the CAN network which assigns the screen number 1. This is necessary for the video and audio to be addressed to the right screen and so that commands from the remote control can be executed on the right screen.
7. Communication for the left-hand screen is now OK.
8. The Rear seat entertainment module (RSE) sends a wake-up signal of approximately 11.5 V to connection #E14 for the right-hand screen.
9. The right-hand screen then returns an OK signal to the Rear seat entertainment module (RSE) via the internal CAN network.

NOTE: **If the screen does not respond on the CAN network, the Rear seat entertainment module (RSE) makes a further two attempts according to the pattern below (*). If the screen does not respond the Rear seat entertainment module (RSE) continues as set out in item 12 below.**

10. The Rear seat entertainment module (RSE) returns a message to the right-hand screen on the CAN network which assigns the screen number 2.
11. Communication for the right-hand screen is now OK.
12. Lighting in the DVD-player's buttons, except the POWER button, goes out.
13. The start-up procedure is implemented and the system switches to standby.
14. The system can now be started using the POWER button on the DVD player or the remote control.

(*) Wake-up signal (signal pattern with a fault)

High signal (approx. 11.5 V) is sent for approx 1 second (first attempt).

If there is no response a low signal is sent (approx. 0 V) for approximately 1 second.

High signal (approx. 11.5 V) is sent for approx 1 second (second attempt).

If there is no response a low signal is sent (approx. 0 V) for approximately 10 seconds.

High signal is sent (approx. 11.5 V) and remains continuously high (third and last attempt).

Start-up times

Start-up without faults detected takes approximately 4-10 seconds.

Start-up with communication fault on one screen takes approximately 20-25 seconds.

Start-up with communication fault on both screens takes approximately 30-35 seconds.

The times above should only be seen as a guide and are not exact times.

REAR AUDIO SEPARATION MODULE (RAS)

Fig. 236: Identifying Rear Audio Separation Module (RAS) Communication Links & Components
Courtesy of VOLVO CARS CORPORATION

The rear audio separation module (RAS) (16/122) is designed to redirect audio signals from the car's internal audio system or from the system's DVD player to the rear speakers (16/5, 16/6, 16/57 and 16/58).

When the unit is in normal mode, audio signals are routed from the front audio system to the rear speakers.

The remote control can be used to activate the rear audio separation module (RAS). Audio signals from the front audio system will then be replaced with audio signals from the rear seat entertainment system.

Which audio channel is connected to the rear speakers is determined by which screen the remote control is aimed at when the button to activate the rear audio separation module (RAS) is pressed.

If a parking assistance system is installed, the control module is temporarily deactivated via an input when reverse gear is engaged. The deactivation signal comes from the same voltage circuit the drives the reversing lights. The parking assistance system signals will then be heard via the rear speakers.

INFRARED (IR) CONTROL

Fig. 237: Identifying Infrared (IR) Control Signal Examples
Courtesy of VOLVO CARS CORPORATION

Each screen houses an IR receiver. The IR receivers are directly connected to the rear seat entertainment module (RSE) (16/82) and are activated when the rear seat entertainment module (RSE) is supplied power. When a button is pressed on the remote control, it emits a signal with infrared light. The coding of this signal varies depending on which button was pressed. The IR signal is received by the IR receiver below the respective head restraint screen (16/81A, B) and is forwarded to the rear seat entertainment module (RSE) for processing.

The remote control can be used to switch between different audio and/or video inputs in the system:

- DVD player, audio/video
- AUX input, audio or audio/video
- Audio from the front audio system to one of the headphones, both headphones or separately to one of the headphones and the rear speakers
- Audio/video from a TV receiver (if installed) to one or both screens.

Selection is carried by pointing the remote control towards the screen to be commanded. Depending on which of the two screens that received the command, the Rear seat entertainment module (RSE) selects AV or audio source for the screen. The remote control can then be pointed to the other screen to select the source for that screen.

HEADPHONES

Fig. 238: Identifying IR Headphone Signal Example
Courtesy of VOLVO CARS CORPORATION

The system includes two pairs of IR headphones as standard. Any number of headphones can be used as long as they are within range of the IR transmitter.

Sound is transferred from the screen to the wireless headphones via an infrared signal. There must be free travel between the transmitter in the bottom edge of the screen and the receivers on the side of the headphones. If the way is blocked, the signal may be interfered with and sound quality will thus deteriorate.

The headphones are switched on with the switch located on the side. The headphones switch off automatically if no IR signal is received for 3-4 minutes.

The headphones also have a button to set which audio channel to listen to. Channel A or B can be selected. Channel A is always transmitted from the left screen and channel B is always transmitted from the right screen.

NOTE: Lowering the volume of the screen will increase the signal/noise ratio of the headphones. Optimal headphone output is obtained by setting screen volume to 75%. Headphone volume can then be regulated using the wheel on the headphones themselves.

IDENTIFICATION OF GENERATION

see **IDENTIFICATION OF GENERATION**

SYSTEM OVERVIEW

REAR SEAT ENTERTAINMENT SYSTEM

Fig. 239: Locating Rear Seat Entertainment System Components
Courtesy of VOLVO CARS CORPORATION

1. Screen, head restraint (16/81A, B)

2. DVD player with integrated Rear seat entertainment module (RSE) (16/82)
3. Rear audio separation module (RAS) (16/122)
4. AUX socket (16/123)
5. Headphones (two)
6. Remote control

The rear seat entertainment system is a mobile entertainment system for keeping rear seat passengers occupied and entertained with video games or movies.

The system is fully integrated in the car and has two separately controlled, high-resolution 7-inch screens mounted in the head restraints.

The rear seat entertainment module (RSE) is integrated in the DVD player and can receive signals from up to three AV inputs and can transmit video to two separately controlled screens. The control module can also send an output signal to an external screen.

The following media formats can be played by the DVD player:

- DVD-R/+R
- DVD-RW/+RW
- CD-R and CD-RW
- CDDA
- HDCD

The following information formats can be played:

- DVD
- DVD Audio
- VCD
- SVCD
- DivX
- WMV
- Audio CD
- Kodak photo CD
- MP3
- MP3 Pro
- playlists in M3U format
- WMA Sound.

Formats such as THX and DolbyDigital are also supported. Only stereo signals of this audio format are reproduced.

A connection panel with AV inputs is mounted on the rear section of the center console. Other audio and video sources can be connected to the system via this panel, such as video cameras, games consoles or portable DVD and CD players.

The system includes two pairs of wireless headphones. Audio is transferred to the headphones via an IR transmitter in each screen. Headphones with wire can be used by connecting them to the socket in the AUX panel on the back of the center console.

Audio can also be played in the rear speakers using the rear audio separation module (RAS).

The system is controlled via an infrared remote control, which can also be used to control the DVD player and the vehicle's front audio system (if installed).

Different versions (generations) of the system

The system comes in different versions depending on which software is installed in the control module/DVD player. There are slight differences in function, primarily when handling system faults. There is no difference between the systems form a hardware perspective.

XC90

For XC90 from VIN 258731, generation 4.1 is installed on the car.

For VINs prior to this number the system is generation 3.

The software version in the car can be read out using the service menu. Access the menu as follows:

Model year 2006:

1. Switch on the system
2. Open the menu:
3. Enter the code: 1971 and press

Model year 2007-:

1. Switch on the system

   NOTE: There must not be a disc in the DVD player.

2. Aim the remote control at a screen and depress the button for child lock for approx. 5 seconds. The menu will be displayed with four stars underneath.

SIGNALS

The tables below include the in and output signals for the units in the system for rear seat entertainment.

NOTE: **The CAN communication given here is only a private CAN between the control module and the screens.**

REAR SEAT ENTERTAINMENT MODULE (RSE)/DVD PLAYER (16/82)

Input signals:	Output signals:
Directly connected: • Commands from remote control via head restraint screens (16/81A, B). • Audio/video signals from AUX panel (16/123).	**Directly connected:** • Audio signals to rear audio separation module (RAS) (16/122). • Rear audio separation module (RAS) (16/122), power supply and ground terminal. • Screen, head restraint (16/81A, B), audio and video signals. • Screen, head restraint (16/81A, B), power supply and ground terminal. • AUX panel (16/123), audio and video signals.
Via Controller Area Network (CAN) communication: • Communication with screens (16/81A, B).	**Via Controller Area Network (CAN) communication:** • Communication with screens (16/81A, B).

REAR AUDIO SEPARATION MODULE (RAS) (16/122)

Input signals:	Output signals:
Directly connected: • Rear seat entertainment module (RSE)/DVD player (16/82), power supply and ground terminal. • Rear seat entertainment module (RSE)/DVD player (16/82), audio signals. • Rear seat entertainment module (RSE)/DVD player (16/82), activation signal. • Input signals from circuit for back-up (reversing) lamps, to indicate engaged reverse gear.	**Directly connected:** • Rear loudspeakers, (16/5, 16/6, 16/57, 16/58).

SCREEN, HEAD RESTRAINT (16/81A, B)

Input signals:	Output signals:
Wireless communication (IR): • Remote control	**Wireless communication (IR):** • IR signals to wireless headphones
Directly connected: • Rear seat entertainment module (RSE)/DVD player (16/82), audio and video signals. • Rear seat entertainment module	**Directly connected:** • Rear seat entertainment module (RSE)/DVD player (16/82), command from remote control.

(RSE)/DVD player (16/82), power supply and ground terminal.	
Via Controller Area Network (CAN) communication: • Rear seat entertainment module (RSE)/DVD player (16/82), control signals.	**Via Controller Area Network (CAN) communication:** • Rear seat entertainment module (RSE)/DVD player (16/82), communication signals.

INFRARED HEADPHONES

Input signals:	Output signals:
Wireless (IR): • Screen, head restraint (16/81A, B), IR signals from transmitter in screen.	**Wireless (IR):** -

REAR SEAT ENTERTAINMENT SYSTEM (RSE), GENERATION 4.2 (2007-2008)

DESIGN

REAR SEAT ENTERTAINMENT MODULE (RSE)/DVD-PLAYER

Fig. 240: Identifying DVD Player
Courtesy of VOLVO CARS CORPORATION

Rear seat entertainment module (RSE) is the central unit in the system for rear seat entertainment.

The control module is integrated with the DVD player and is located at the rear edge of the center console.

The control module interprets and executes the commands given by the user with the system's infrared remote control. These commands are transmitted from the remote control to Rear seat entertainment module (RSE) via system's infrared receivers in the screens. Rear seat entertainment module (RSE) also distributes current to the system's other components.

Rear seat entertainment module (RSE) distributes audio and video signals from the DVD-player to screens and

speakers in the system. Via external inputs, other audio and video sources can also be connected, e. g., game pads or video cameras.

The DVD player mechanism has an anti-shock system and it helps to prevent the image or sound skipping when played. The DVD player has slot-in disc insertion and region coding programmed into the software. The region code can be changed using a security code.

The following media formats can be played by the DVD player:

- DVD-R/+R
- DVD-RW/+RW
- CD-R and CD-RW
- CDDA
- HDCD

The following information formats can be played:

- DVD
- DVD Audio
- VCD
- SVCD
- DivX
- WMV
- Audio CD
- Kodak photo CD
- MP3
- MP3 Pro
- playlists in M3U format
- WMA Sound.

Formats such as THX and DolbyDigital are also supported. Only stereo signals of this audio format are reproduced.

The control module is supplied with power from the Ext. X-supply in the Central electronic module and directly from the battery.

To easily check whether the control module is powered and grounded, switch on the ignition. The background illumination on the function buttons should then come on.

CHANGE OF DVD PLAYER REGION CODE

The region coding means that only discs with the region code matching that of the DVD player can be played.

The region code in the DVD player can be changed up to 10 times. After the 11th change, the set region will

then be locked and it will not be possible to change again.

NOTE: Warranty repairs due to locked region on the DVD player will not be approved. Region code changes to the region in which the vehicle will be used is to be done at the workshop. The security code is not to be given to the customer.

Do as follows to open the menu for region code change:

1. Switch on the ignition.
2. Switch on the system

   NOTE: There must not be a disc in the DVD player.

3. Aim the remote control at a screen and depress the button for child lock for approx. 5 seconds. The menu will be displayed with four stars underneath.
4. Enter the code 1971 using the arrow keys on the remote control and then press OK.
5. Select menu selection and press OK.
6. Select the region code which applies to the relevant vehicle and press OK.
7. Check that the set region code, which will be shown in the top left-hand corner of the screen corresponds with the region where the vehicle will be used.
8. Switch off the system

The submenu can then be used to select a new region for the DVD player.

AUX-INPUT

Fig. 241: Identifying Aux-Input 3.5 mm Stereo Connection
Courtesy of VOLVO CARS CORPORATION

In order to playback audio from the rear seat entertainment system using the vehicle's ordinary audio system, the Rear seat entertainment module (RSE) is connected to the regular AUX input.

The AUX-input is a 3.5 mm stereo connection and can be used to connect, e. g., a portable CD-player or other

media player to the system.

The connection is breaking which means, if nothing is connected, it is the audio signals from the Rear seat entertainment module (RSE)/DVD-player that are forwarded to the Integrated Audio Module (IAM).

When something is connected, this connection is broken and the audio from the connected unit is forwarded instead to the Integrated Audio Module (IAM).

Internal electrical connections:

- AUX input connection #1 is internally connected to AUX input #7.
- AUX input connection #2 is internally connected to AUX input #6. The circuit is broken when a 3.5 mm plug is connected.
- AUX input connection #3 is internally connected to AUX input #5. The circuit is broken when a 3.5 mm plug is connected.

SCREEN, HEAD RESTRAINT

Fig. 242: Identifying Rear Facing Head Restraint Video Screen
Courtesy of VOLVO CARS CORPORATION

The multimedia head restraint consists of five main components:

- Screen
- Circuit board
- Rear piece
- Border
- Head restraint pad

The rear piece is fastened in an opening on the rear of the head restraint pad. The circuit board is held in place in the rear piece with three screws. The screen is housed in the rear piece in front of the circuit board and is connected with a flexible foil cable and an AC lead. The border holds all electronic components in place in the rear piece in the head restraint pad. The lower edge of the border contains a window so that the infrared receiver on the circuit board can receive infrared signals from the remote control. The infrared receiver is separately

connected to the rear seat entertainment module (RSE) and is activated when the rear seat entertainment module (RSE) is on.

The 7-inch screen in the head restraint has an aspect ratio of 16:9. The screen is positioned to provide the optimal viewing angle. The screen has a 120 degree horizontal viewing angle.

The integrated infrared receiver is activated when Rear seat entertainment module (RSE) receives voltage supply. The screen is not activated until it receives a high signal on the wake-up cable from Rear seat entertainment module (RSE)/DVD-player.

This signal is sent when the system is switched on with the POWER button on the remote control or with the POWER button on the control module.

The circuit board contains an image generator, infrared receiver, infrared transmitter and the unit that controls all screen settings:

- colour
- contrast
- brightness
- aspect ratio.

Damping control has a damping relationship of 30:1 to improve the image and reduce bright light from light day conditions down to complete darkness. Brightness can be adjusted so that the screen's image easily can be seen in daylight as well. Voltage protection and power supply of the screens background lighting also take place via the circuit board. The control module contains logic for interpreting commands for setting video performance, input selection, and intensity of background lighting. Control commands are sent from Rear seat entertainment module (RSE) via a private CAN-net.

Each screen has an integrated infrared transmitter to send sound signals to the wireless headphones.

The screens are supplied power and grounded via the rear seat entertainment module (RSE).

To check whether a screen has power and ground, you can switch on the ignition and then switch on the system with the remote control. The screen will then come on.

NOTE: **If voltage supply and ground to the screen work but the screen has no contact with Rear seat entertainment module (RSE)/DVD-player, the screen will still be activated in LOCAL-mode. However, this is no guarantee that the whole system works. For more information, see : TROUBLESHOOTING INFORMATION If the screen works in LOCAL-mode this indicates that voltage supply and ground to the screen's circuit board are okay.**

REMOTE CONTROL

Fig. 243: Identifying Remote Control
Courtesy of VOLVO CARS CORPORATION

The remote control is used to control Rear seat entertainment module (RSE)/DVD-player and the screens. The remote control has 22 buttons, one is red and 21 are white.

The remote control uses infrared signals (IR) to transfer commands to the system. The signals are received by the screens' infrared receivers.

The remote control is equipped with two batteries, fitted under a cover at the rear.

HEADPHONES

Fig. 244: Identifying Headphones
Courtesy of VOLVO CARS CORPORATION

The wireless IR-headphones can be used for both screens. The standard sound is transmitted via IR-transmission to the headphones in two-channel stereo format. The headphones are driven by an internal battery.

The headphones are turned on with a button on one side, and the volume, in each headphone, can be adjusted with a knob. Each kit also has a channel selector, that controls which audio channel the headphone receives.

The audio from the left screen is always transmitted on channel A and the audio from the right screen is always transmitted on channel B.

AV-PANEL

Fig. 245: Identifying AV-Panel With External Input Terminals
Courtesy of VOLVO CARS CORPORATION

On the rear of the center console there is an AV-panel with external input terminals for audio/video. This input can be used for supplying standard AV signals to systems, such as, video cameras, video game consoles, VHS videos, portable DVD or CD-players.

All inputs on the AV-panel are directly connected to Rear seat entertainment module (RSE)/DVD-player.

DIAGNOSTIC FUNCTIONS

TROUBLESHOOTING INFORMATION

For diagnostics the Rear seat entertainment module (RSE)/DVD-player has a basic internal system check and a start-up procedure for the screens.

The control module is not connected to the vehicle's other CAN networks. This means for example that **no** diagnostic trouble codes (DTCs) can be read from the control module. All fault tracing must therefore be carried out via symptom fault tracing.

The following is information that may facilitate when fault tracing in the system.

When the ignition is switched on the Rear seat entertainment module (RSE) performs a basic internal system check and starts the start-up procedure with the screens.

If the time from when the ignition is switched on until the system is in standby mode (only the illuminated POWER button is lit) is longer than normal, this indicates a communication fault with the screens.

The start-up times, see: **SYSTEM START-UP PROCEDURE**

Causes of a long start-up time can be:

- No supply voltage and ground to the screen

- Damaged wake-up signal cable.
- Damaged cables for the internal CAN network (no communication can take place). In connector D on the Rear seat entertainment module (RSE)/DVD-player the CAN network is strapped for the *right-hand screen* . The strap is used to support the future expansion of the system with additional devices. If connector D has been damaged, has become dislodged or for some reason there is no connection between both ends of the strap on the CAN cables, it will not be possible to establish communication.

Switch on the system using the POWER button on the DVD player

If one of the screens does not start when the system is switched on, when the start-up procedure has elapsed over the normal time (without fault), and only the POWER lamp on the control module/DVD player is lit, this indicates a fault with the actual screen or the cables between the screen and the circuit board.

When communication with the control modules/DVD player in this case is okay, both these screens' circuit boards behind the actual screens are OK.

The functionality of the circuit boards can also be checked by switch on the system and checking whether the IR lamps in the bottom of the screen are slightly illuminated.

The IR-lights are lit for about 2 minutes after the system is switched on or when sound is played from a selected audio source.

Switch on the system using the remote control

If the system is switched on using the remote control aimed towards the right-hand screen, when the voltage supply and ground to the screen are fully functional but for example there is no CAN-communication with the Rear seat entertainment module (RSE)/DVD-player, the screen will be lit and work in LOCAL mode. It will then be possible to show the menus and to adjust the sound and brightness settings.

This can be misinterpreted as the function is OK. However no image will be shown on screen if, for example, you play a DVD disc. The system will be switched on and the left-hand screen will start. This is because the cables for the IR signals do not go via the CAN network, but go directly to the DVD player and are interpreted.

If the screen works in LOCAL mode this indicates that the voltage supply and ground to the screen's circuit board are OK.

FUNCTION

REAR SEAT ENTERTAINMENT MODULE

Fig. 246: Identifying Rear Seat Entertainment Network
Courtesy of VOLVO CARS CORPORATION

NOTE: **There may be a slight delay between selecting a DVD function with the remote control and activation of the DVD player function. A message will appear on the screen to confirm that the DVD function was selected. Display of indicates that the DVD player is still processing a previously selected function.**

The rear seat entertainment system is supplied with electric power and is controlled by the rear seat entertainment module (RSE) (16/109).

The control module also includes the DVD player for the system.

The system is powered via X-feed and directly from the battery. If the system is operating when the ignition is switched of, a question will appear on the screens as to whether continued play is permitted.

If the user answers YES, the system will continuing playing another 10 minutes. The system will then shut down. If there is no response to the question, the system will shut down after 1 minute. As a means of safeguarding the battery, play time cannot be extended unless the ignition is switched on again.

All buttons will light for approximately 5-10 seconds when attempting to start the system using the POWER button on the DVD player in this mode, they will then go out. Accordingly, the system is not permitted to start before the ignition has been switched on again.

If the system is to be switched on using the remote control, the ignition must be switched on and the remote control must be pointed at one of the screens before any buttons are depressed, the receiver for the signals from the remote control is located on the lower edge of the screens.

When the remote control is aimed at a screen (16/81A, B) and a function key is pressed in, the Rear seat entertainment module (RSE) identifies the selected screen and executes the command that the remote control sent out.

If, for example, you press a menu selection button, a menu opens on the screen at which the remote control was aimed. The possible selections are described below:

- Independent shifting of three audio/video inputs (DVD and AUX).
- Image adjustment (image color, brightness, contrast and aspect ratio).
- Audio settings (bass, treble and volume).
- Language selection for on-screen instructions.
- Switch individual screens ON/OFF.

Rear seat entertainment module (RSE) also decides which media source that has been linked to the selected screen and transmits command in a suitable protocol.

If, for example, the left screen is set for DVD-playback and an infrared play command is detected at the left screen, the message is received, saved and forwarded to the DVD-player (16/109) in the DVD-player's infrared protocol.

A fixed memory saves the displayed instruction language used and the current audio and video settings for the respective output channel. These settings are loaded upon start-up with the exception of volume level, which is set to low as standard.

When a DVD disc is inserted in the opening DVD playback starts automatically if the DVD disc does not have a disc menu.

DVD playback can resume from a paused position, for example, if the ignition was switched off when watching a movie. In this case playback continues from the last position when the ignition is switched on again. The audio and video signals are fed out from the DVD player from the connection block (ISO connection) at the rear of the device.

SYSTEM START-UP PROCEDURE

When the ignition is switched on the Rear seat entertainment module (RSE) performs a basic internal system check and starts the start-up procedure with the screens.

Depending on software, the start-up times are different and handling of the POWER-button's lighting. Version of software can be identified using the SERVICE MENU, see: **CHANGE OF DVD PLAYER REGION CODE**

The following takes place:

Software, version DVD TMS S/W 2.1.3 (a newer software)

1. The ignition is switched on.
   - If the wake-up attempt and communication check are OK, the control module continues as set out in section 14.
   - If both the wake-up attempt/communication check fail, the control module continues as set out in section 13.
2. Lighting in the DVD-player's buttons is activated.
   - If the wake-up attempt and communication check are OK, the control module continues as set out in section 14.
   - If both the wake-up attempt/communication check fail, the control module continues as set out in section 13.
3. The Rear seat entertainment module (RSE) feeds the connections #E1 (left-hand screen) and #E13 (right-hand screen) with voltage.
   - If the wake-up attempt and communication check are OK, the control module continues as set out in section 14.
   - If both the wake-up attempt/communication check fail, the control module continues as set out in section 13.
4. The Rear seat entertainment module (RSE) sends a wake-up signal of approximately 11.5 V to connection #E2 for the left-hand screen.
   - If the wake-up attempt and communication check are OK, the control module continues as set out in section 14.
   - If both the wake-up attempt/communication check fail, the control module continues as set out in section 13.
5. The left-hand screen then returns an OK signal to the Rear seat entertainment module (RSE) via the internal CAN network.

   NOTE: If the screen does not respond on the CAN network, the Rear seat entertainment module (RSE) makes a further two attempts according to the pattern below (*). If the screen does not respond the Rear seat entertainment module (RSE) continues as set out in section 8 below.

   - If the wake-up attempt and communication check are OK, the control module continues as set out in section 14.
   - If both the wake-up attempt/communication check fail, the control module continues as set out in section 13.
6. The Rear seat entertainment module (RSE) returns a message to the left-hand screen on the CAN network which assigns the screen number 1. This is necessary for the video and audio to be addressed to the right screen and so that commands from the remote control can be executed on the right screen.
   - If the wake-up attempt and communication check are OK, the control module continues as set out in section 14.
   - If both the wake-up attempt/communication check fail, the control module continues as set out in section 13.

7. Communication for the left-hand screen is now OK.
   - If the wake-up attempt and communication check are OK, the control module continues as set out in section 14.
   - If both the wake-up attempt/communication check fail, the control module continues as set out in section 13.
8. The Rear seat entertainment module (RSE) sends a wake-up signal of approximately 11.5 V to connection #E14 for the right-hand screen.
   - If the wake-up attempt and communication check are OK, the control module continues as set out in section 14.
   - If both the wake-up attempt/communication check fail, the control module continues as set out in section 13.
9. The right-hand screen then returns an OK signal to the Rear seat entertainment module (RSE) via the internal CAN network.

   NOTE: If the screen does not respond on the CAN network, the Rear seat entertainment module (RSE) makes a further two attempts according to the pattern below (*). If the screen does not respond the Rear seat entertainment module (RSE) continues as set out in item 12 below.

   - If the wake-up attempt and communication check are OK, the control module continues as set out in section 14.
   - If both the wake-up attempt/communication check fail, the control module continues as set out in section 13.
10. The Rear seat entertainment module (RSE) returns a message to the right-hand screen on the CAN network which assigns the screen number 2.
    - If the wake-up attempt and communication check are OK, the control module continues as set out in section 14.
    - If both the wake-up attempt/communication check fail, the control module continues as set out in section 13.
11. Communication for the right-hand screen is now OK.
    - If the wake-up attempt and communication check are OK, the control module continues as set out in section 14.
    - If both the wake-up attempt/communication check fail, the control module continues as set out in section 13.
12. The Rear seat entertainment module (RSE) checks whether the result of the wake-up attempt according to section 7 and 11 is OK. It then performs a communication check with the DVD player.
    - If the wake-up attempt and communication check are OK, the control module continues as set out in section 14.
    - If both the wake-up attempt/communication check fail, the control module continues as set out in section 13.
13. The illuminated DVD player buttons are on for approximately 60 seconds.
14. Lighting in the DVD-player's buttons, except the POWER button, goes out.

15. The start-up procedure is implemented and the system switches to standby.
16. The system can now be started using the POWER button on the DVD player or the remote control.

(*) Wake-up signal (signal pattern with a fault)

High signal (approx. 11.5 V) is sent for approx 1 second (first attempt).

If there is no response a low signal is sent (approx. 0 V) for approximately 3 seconds.

High signal (approx. 11.5 V) is sent for approx 1 second (second attempt).

If there is no response a low signal is sent (approx. 0 V) for approximately 3 seconds.

High signal is sent (approx. 11.5 V) and remains continuously high (third and last attempt).

Start-up times

Start-up without faults detected takes approximately 10 seconds.

Start-up with communication fault on one screen takes approximately 85 seconds.

Start-up with communication fault on both screens takes approximately 95 seconds.

The times above should only be seen as a guide and are not exact times.

Software, version DVD TMS S/W 3.0.0 and 2.1.1 (an older software)

1. The ignition is switched on.
2. Lighting in the DVD-player's buttons is activated.
3. The Rear seat entertainment module (RSE) feeds the connections #E1 (left-hand screen) and #E13 (right-hand screen) with voltage.
4. The Rear seat entertainment module (RSE) sends a wake-up signal of approximately 11.5 V to connection #E2 for the left-hand screen.
5. The left-hand screen then returns an OK signal to the Rear seat entertainment module (RSE) via the internal CAN network.

NOTE: **If the screen does not respond on the CAN network, the Rear seat entertainment module (RSE) makes a further two attempts according to the pattern below (*). If the screen does not respond the Rear seat entertainment module (RSE) continues as set out in section 8 below.**

6. The Rear seat entertainment module (RSE) returns a message to the left-hand screen on the CAN network which assigns the screen number 1. This is necessary for the video and audio to be addressed to the right screen and so that commands from the remote control can be executed on the right screen.
7. Communication for the left-hand screen is now OK.

8. The Rear seat entertainment module (RSE) sends a wake-up signal of approximately 11.5 V to connection #E14 for the right-hand screen.
9. The right-hand screen then returns an OK signal to the Rear seat entertainment module (RSE) via the internal CAN network.

NOTE: **If the screen does not respond on the CAN network, the Rear seat entertainment module (RSE) makes a further two attempts according to the pattern below (*). If the screen does not respond the Rear seat entertainment module (RSE) continues as set out in item 12 below.**

10. The Rear seat entertainment module (RSE) returns a message to the right-hand screen on the CAN network which assigns the screen number 2.
11. Communication for the right-hand screen is now OK.
12. Lighting in the DVD-player's buttons, except the POWER button, goes out.
13. The start-up procedure is implemented and the system switches to standby.
14. The system can now be started using the POWER button on the DVD player or the remote control.

(*) Wake-up signal (signal pattern with a fault)

High signal (approx. 11.5 V) is sent for approx 1 second (first attempt).

If there is no response a low signal is sent (approx. 0 V) for approximately 1 second.

High signal (approx. 11.5 V) is sent for approx 1 second (second attempt).

If there is no response a low signal is sent (approx. 0 V) for approximately 10 seconds.

High signal is sent (approx. 11.5 V) and remains continuously high (third and last attempt).

Start-up times

Start-up without faults detected takes approximately 4-10 seconds.

Start-up with communication fault on one screen takes approximately 20-25 seconds.

Start-up with communication fault on both screens takes approximately 30-35 seconds.

The times above should only be seen as a guide and are not exact times.

For more information about the procedure at start, see: **TROUBLESHOOTING INFORMATION**

PLAYBACK OF AUDIO IN THE VEHICLE'S FIXED AUDIO SYSTEM

Fig. 247: Identifying Fixed Audio System Network
Courtesy of VOLVO CARS CORPORATION

In order to playback audio from the DVD player using the vehicle's ordinary audio system the Rear seat entertainment module (RSE)/DVD player is connected to the AUX input on the Integrated Audio Module (IAM).

Audio from the DVD-player or AUX-input can be selected as audio source on Integrated Audio Module (IAM) by selecting input signal "AUX" in the audio system's menu system.

When Rear seat entertainment module (RSE)/DVD-player plays a disc, the audio is automatically sent out on the outputs to the Integrated Audio Module (IAM). But no sound will be heard in the speakers until "AUX" has been selected as the audio source.

NOTE: If an audio source is connected to the AUX input's 3.5 mm stereo connection, the audio signals from the Rear seat entertainment module (RSE)/DVD player to the Integrated Audio Module (IAM) are disconnected.

INFRARED (IR) CONTROL

Fig. 248: Remote Control Emitting A Signal With Infrared
Courtesy of VOLVO CARS CORPORATION

Each screen houses an IR-receiver. The IR-receivers are connected to the rear seat entertainment module (RSE) (16/109) and are activated when the rear seat entertainment module (RSE) is supplied power. When a button is pressed on the remote control, it emits a signal with infrared light. The coding of this signal varies depending on which button was pressed. The IR-signal is received by the IR-receiver below the respective head restraint screen (16/81A, B) and is forwarded to the rear seat entertainment module (RSE) for processing.

The remote control can be used to switch between different audio and/or video inputs in the system:

- DVD player, audio/video
- AV-panel, audio or audio/video
- Audio/video from a TV receiver (if installed) to one or both screens.

Selection is performed by aiming the remote control at the screen where the command is to be executed.

Depending on which of the two screens that received the command, the Rear seat entertainment module (RSE) will select AV- or audio source for that screen. Then the remote control can be aimed at the other screen to select source for that screen.

HEADPHONES

Fig. 249: Identifying IR Headphone Signal Example
Courtesy of VOLVO CARS CORPORATION

The system includes two pairs of IR headphones as standard. Any number of headphones can be used as long as they are within range of the IR transmitter.

Sound is transferred from the screen to the wireless headphones via an infrared signal. There must be free travel between the transmitter in the bottom edge of the screen and the receivers on the side of the headphones. If the way is blocked, the signal may be interfered with and sound quality will thus deteriorate.

The headphones are switched on with the switch located on the side. The headphones switch off automatically if no IR signal is received for 3-4 minutes.

The headphones also have a button to set which audio channel to listen to. Channel A or B can be selected. Channel A is always transmitted from the left screen and channel B is always transmitted from the right screen.

NOTE: **Lowering the volume of the screen will increase the signal/noise ratio of the headphones. Optimal headphone output is obtained by setting screen volume to 75%. Headphone volume can then be regulated using the wheel on the headphones themselves.**

IDENTIFICATION OF GENERATION

see **IDENTIFICATION OF GENERATION**

SYSTEM OVERVIEW

REAR SEAT ENTERTAINMENT SYSTEM

Fig. 250: Rear Seat Entertainment System Components
Courtesy of VOLVO CARS CORPORATION

1. Screen, head restraint (16/81A, B)
2. DVD-player with integrated Rear seat entertainment module (RSE) (16/109)
3. AUX-input (17/40.1)
4. AV-panel (16/123.3)
5. Headphones (two)
6. Remote control

The system for rear seat entertainment is a mobile entertainment to keep the rear seat passengers occupied and amused with TV-games or movies.

The system is fully integrated in the car and has two separately controlled, high-resolution 7-inch screens mounted in the head restraints.

There is an internal CAN network between the Rear seat entertainment module (RSE)/DVD-player and the screens for the transfer of information. This CAN network is not connected to the vehicle's ordinary CAN network.

Rear seat entertainment module (RSE) is integrated in the DVD-player and can receive signals from up to three AV-inputs and supply video to two separately controlled screens. The control module can also supply output signal to an external screen.

The following media formats can be played by the DVD player:

- DVD-R/+R
- DVD-RW/+RW
- CD-R and CD-RW
- CDDA
- HDCD

The following information formats can be played:

- DVD
- DVD Audio
- VCD
- SVCD
- DivX
- WMV
- Audio CD
- Kodak photo CD
- MP3
- MP3 Pro
- playlists in M3U format
- WMA Sound.

Formats such as THX and DolbyDigital are also supported. Only stereo signals of this audio format are reproduced.

A connection panel with AV inputs is mounted on the rear section of the center console. Other audio and video sources can be connected to the system via this panel, such as video cameras, games consoles or portable DVD and CD players.

Two pairs of wireless headphones are included in the system. The sound is transferred to the headphones via an IR transmitter in each screen.

Audio can also be played in the vehicle's ordinary speakers via the connection from Rear seat entertainment module (RSE) to Integrated Audio Module (IAM).

Wired headphones can also be connected if the vehicle is equipped with headphone panels in the C-posts. The panels are available as accessories to the vehicle's audio system and are not directly included in the rear seat entertainment system.

In the storage compartment between the front seats there is also an AUX-input where, e. g., a portable CD or media player can be connected. When an audio source is connected, the sound from it can be played in the vehicle's ordinary speakers, by selecting "AUX" as audio source on the audio panel.

The system is controlled using an infrared (IR) remote control, which also can be used to control the DVD-player and screens.

SIGNALS

The following tables summarize input and output signals to the units in the system for rear seat entertainment.

NOTE: The CAN communication given here is only a private CAN between the control module and the screens.

REAR SEAT ENTERTAINMENT MODULE (RSE)/DVD-PLAYER (16/109)

Input signals:	Output signals:
Directly connected: • Commands from remote control via head restraint screens (16/81A, B). • Audio/video signals from AV-panel (16/123.3).	**Directly connected:** • Screen, head restraint (16/81A, B), audio and video signals. • Screen, head restraint (16/81A, B), power supply and ground terminal. • Screen, head restraint (16/81A, B), wake-up signal. • AUX-input (17/40:1), audio and video signals to the vehicle's audio system.
Via CAN communication: • Communication with screens (16/81A, B).	**Via CAN communication:** • Communication with screens (16/81A, B).

SCREEN, HEAD RESTRAINT (16/81A, B)

Input signals:	Output signals:
Wireless communication (IR): • Remote control	**Wireless communication (IR):** • IR signals to wireless headphones
Directly connected: • Rear seat entertainment module	**Directly connected:**

(RSE)/DVD-player (16/109), audio and video signals. • Rear seat entertainment module (RSE)/DVD-player (16/109), wake-up signal. • Rear seat entertainment module (RSE)/DVD-player (16/109), voltage feed and ground connection.	• Rear seat entertainment module (RSE)/DVD player (16/109), command from remote control.
Via CAN communication: • Rear seat entertainment module (RSE)/DVD-player (16/109), control signals.	**Via CAN communication:** • Rear seat entertainment module (RSE)/DVD-player (16/109), communication signals.

WIRELESS HEADPHONES

Input signals:	Output signals:
Wireless communication (IR): • Screen, head restraint (16/81A, B), IR signals from transmitter in screen.	**Wireless communication (IR):** -

REAR SEAT ENTERTAINMENT SYSTEM (RSE), GENERATION 4.3 (2009-2012)

DESIGN

REAR SEAT ENTERTAINMENT MODULE (RSE)/DVD-PLAYER

Fig. 251: Identifying DVD Player
Courtesy of VOLVO CARS CORPORATION

Rear seat entertainment module (RSE) is the central unit in the system for rear seat entertainment.

The control module is integrated with the DVD player and is located in the storage tray in the centre console. In XC90 it is located at the rear edge of the centre console.

The control module interprets and executes the commands given by the user with the system's infrared remote control. These commands are transmitted from the remote control to Rear seat entertainment module (RSE) via system's infrared receivers in the screens. Rear seat entertainment module (RSE) also distributes current to the system's other components.

The Rear seat entertainment module (RSE) distributes audio and video signals from the DVD player or digital TV receiver to the screen and speakers in the system. Other audio and video sources can be connected via external inputs (AV panel), for example, games consoles or video cameras.

There is an internal CAN network between the Rear seat entertainment module (RSE)/DVD-player and the screens for the transfer of information. This CAN network is not connected to the vehicle's ordinary CAN network.

The DVD player mechanism has an anti-shock system and it helps to prevent the image or sound skipping when played. The DVD player has slot-in disc insertion and region coding programmed into the software. The region code can be changed using a security code.

The following media formats can be played by the DVD player:

- DVD-R/+R
- DVD-RW/+RW
- CD-R and CD-RW
- CDDA
- HDCD

The following information formats can be played:

- DVD
- DVD Audio
- VCD
- SVCD
- DivX
- WMV
- Audio CD
- Kodak photo CD
- MP3
- MP3 Pro
- playlists in M3U format
- WMA Sound.

Formats such as THX and DolbyDigital are also supported. Only stereo signals of this audio format are reproduced.

The control module is supplied with power from the Ext. X-supply in the Central electronic module (CEM) and

directly from the battery.

To easily check whether the control module is powered and grounded, switch on the ignition. The background illumination on the function buttons should then come on.

Change of DVD player region code

The region coding means that only discs with the region code matching that of the DVD player can be played.

The region code in the DVD player can be changed up to 25 times. After the last change, the set region will be locked and it will not be possible to change again.

NOTE: Warranty repairs due to locked region on the DVD player will not be approved. Region code changes to the region in which the vehicle will be used is to be done at the workshop. The security code is not to be given to the customer.

Do as follows to open the menu for region code change:

1. Switch on the ignition.
2. Switch on the system.

   NOTE: There must not be a disc in the DVD player.

3. Direct the remote-control towards one of the screens and press and hold the Day/Night switching button for approx. 5 seconds. The SERVICE MENU will now be shown with four stars below.
4. Enter the code 1971 using the arrow keys on the remote control and then press OK.
5. Select menu REGION CODE and press OK.
6. Select the region code which applies to the relevant vehicle and press OK.
7. Check that the set region code, which will be shown in the top left-hand corner of the screen corresponds with the region where the vehicle will be used.
8. Switch off the system.

The submenu can then be used to select a new region for the DVD player.

AUX-INPUT

Fig. 252: Identifying Aux-Input 3.5 mm Stereo Connection
Courtesy of VOLVO CARS CORPORATION

In order to playback audio from the rear seat entertainment system using the vehicle's ordinary audio system, the Rear seat entertainment module (RSE) is connected to the regular AUX input.

The AUX-input is a 3.5 mm stereo connection and can be used to connect, e. g., a portable CD-player or other media player to the system.

The connection is breaking which means, if nothing is connected, it is the audio signals from the Rear seat entertainment module (RSE)/DVD-player that are forwarded to the Integrated Audio Module (IAM).

When something is connected, this connection is broken and the audio from the connected unit is forwarded instead to the Integrated Audio Module (IAM).

Internal electrical connections:

- AUX input connection #1 is internally connected to AUX input #7.
- AUX input connection #2 is internally connected to AUX input #6. The circuit is broken when a 3.5 mm plug is connected.
- AUX input connection #3 is internally connected to AUX input #5. The circuit is broken when a 3.5 mm plug is connected.

SCREEN, HEAD RESTRAINT

Fig. 253: Identifying Multimedia Head Restraint
Courtesy of VOLVO CARS CORPORATION

The multimedia head restraint consists of the following main components:

- Screen unit with integrated holder and circuit board.
- Head restraint pad.

The screen is attached to the opening on the rear of the head restraint cushion and is held in position in the head restraint cushion frame by two screws.

On the lower edge of the screen there is a window so that infrared signals (IR) from the remote control can be received by the infrared receiver on the screen's circuit board, and the integrated infrared red transmitter can send audio signals to the wireless headphones.

The 8-inch screen in the head restraint has an aspect ratio of 16:9. The screen is positioned to provide the optimal viewing angle. The screen has a 120 degree horizontal viewing angle.

The screen has an integrated temperature sensor that registers the temperature inside the screen. The temperature signal is sent to the Rear seat entertainment module (RSE)/DVD-player via the CAN network to prevent the use of the screens with a two high or low temperature.

The temperature is not monitored during the first 5 minutes after the ignition has been switched on. This is to prevent the system being switched off unnecessarily if, for example, the temperature is too high in the passenger compartment when the vehicle is started. If the temperature is high the climate unit is usually used to lower the temperature.

The following occurs:

- At +72 °C (-19 °C) a warning is shown on the screen. The warning message clears if the temperature changes to +70 °C (-17 °C).
- If the temperature changes to +77 °C (-24 °C) the system will also switches off.

NOTE: The temperature limits above apply inside the screen and not to the temperature in the passenger compartment.

The integrated infrared receiver is activated when the Rear seat entertainment module (RSE) is voltage fed. The receiver receives infrared signals from the remote control executes these commands.

The infrared receiver is also directly connected to the Rear seat entertainment module (RSE). When the ignition is switched on, the LEDs on the infrared receiver and transmitter should be slightly illuminated. The LEDs are on for approx. 2 minutes after the system has been switched on and when audio is played back from a selected audio source.

The screens are not activated until the system has been switched on using the POWER button on the remote control or the POWER button on the DVD player. Before the screens can be activated the Rear seat entertainment module (RSE) must establish communication with the integrated circuit board in the screens. This is performed directly when the ignition is switched on and normally takes approx. 8-10 seconds

The circuit board contains an image generator, infrared receiver, infrared transmitter and the unit that controls all screen settings:

- colour
- contrast
- brightness
- aspect ratio.

The dampening control has a dampening factor of 30:1 to improve the image and reduce sharp light from bright day conditions down to complete dark. The brightness can be adjusted so that the image can be easily seen in daylight. The control module contains logic to interpret commands for setting video performance, input selection and the strength of the background lighting. Control commands are sent from the Rear seat entertainment module (RSE) via a private CAN network.

The screens are supplied power and grounded via the rear seat entertainment module (RSE).

To check whether a screen has power and ground, you can switch on the ignition and then switch on the system with the remote control. The screen will then come on.

NOTE: **If the voltage supply and ground to the screen work, but the screen does not have contact with the Rear seat entertainment module (RSE)/DVD-player via the CAN network, the screen will start up and be lit in LOCAL mode. However this is not a guarantee that the complete system works.**

For further information, see: **DIAGNOSTIC FUNCTIONS**

If the screen works in LOCAL mode this indicates that the voltage supply and ground to the screen's circuit board are OK.

REMOTE CONTROL

Fig. 254: Remote Control Available In 2 Designs
Courtesy of VOLVO CARS CORPORATION

The remote control is used to control the Rear seat entertainment module (RSE)/DVD player, screens, TV receiver (if the accessory is installed).

The remote control is available in 2 designs. If the system is equipped with TV the remote control has 17 buttons.

If the system is equipped with TV (DVB-T) the remote control has 29 buttons.

The remote control uses infrared signals (IR) to transfer commands to the system. The signals are received by the screens' infrared receivers.

The remote control is equipped with two batteries, fitted under a cover at the rear.

HEADPHONES

Fig. 255: Identifying Headphones
Courtesy of VOLVO CARS CORPORATION

The wireless headphones can be used on both screens. The sound to the headphones is transferred from the screen via infrared signals (IR) to the headphones in two channel stereo format. The headphones are powered by an internal battery.

The headphones are switched on using a button on the side and the volume, in each earpiece, can be adjusted using a knob. The headphones also have a channel selector which controls the audio channel received by the headphones. The sound from the left-hand screen is always sent on channel A and the sound from the right-hand screen is always sent on channel B. A LED is lit when the headphones are switched on.

AV-PANEL

Fig. 256: Identifying AV-Panel With External Input Terminals
Courtesy of VOLVO CARS CORPORATION

There is an AV panel with external input connections for audio/video in the storage tray in the centre console in front of the DVD player. In XC90 this is positioned at the rear of the centre console.

This input can be used to feed standard AV signals to the system from e. g. a video camera, video games console, VHS video, portable DVD or CD player.

All inputs on the AV-panel are directly connected to Rear seat entertainment module (RSE)/DVD-player.

DIGITAL TV RECEIVER (DVB-T)

Fig. 257: Identifying Digital TV Receiver (DVB-T)
Courtesy of VOLVO CARS CORPORATION

The digital TV receiver (DVB-T) is an extra option that can receive digital TV channels, convert them and send

them on to the Rear seat entertainment module (RSE).

Two antennas are connected to the receiver so that the TV receiver is able to receive and send the channels.

DVB stands for Digital Video Broadcasting and is a series of internationally accepted open technical standards for digital television. The suffix "T" stands for Terrestrial and alludes to the subset of standards that regulate how a digital TV signal should appear when transmitted terrestrially.

In XC90 the receiver is installed in the cargo compartment, on the right-hand side under the cover above the wheel housing.

The following connections, switches and card slots can be found on the TV receiver:

1. Connection to the vehicle and Rear seat entertainment module (RSE) the two connectors.
2. Connections for two antennas.
3. Slot for a subscription/program card.
4. Serial communications port (serial port RS232).
5. Reset button.
6. Two functions switches.
7. Green status LED.

The TV receiver is voltage fed directly from the battery via connector #A4 for the Rear seat entertainment module (RSE) and then a fuse. The fuse holder is on the TV receiver.

To easily, see whether the receiver is voltage fed and ground switch on the ignition. The status LED should then be lit green.

Subscription/program card

Used to watch paid-by-view channels.

Serial communications port (serial port RS232)

Used to connect a computer when updating the software.

NOTE: Special instructions are issued when this is to be performed.

Reset button

Used to restart the TV receiver when the ignition is on. Switching the ignition off and on has the same effect.

Function switches

Used to:

- Change the signal standard between PAL and NTSC.
- Switch the TV receiver to software update mode.
- Deleting stored TV channels.

Fig. 258: Viewing Function Switches
Courtesy of VOLVO CARS CORPORATION

The following settings are possible:

1. Normal mode
2. Software update mode
3. Mode to delete programmed TV channels.
4. Mode to change signal standard between PAL and NTSC.

To initiate one of the settings, proceed as follows:

1. Ignition on.
2. Set the switches to the required mode as set out above.
3. Ignition off and on again. This initiates the selected function. As an option the reset button can be used instead of switching the ignition off and on.
4. The selected function is now initiated.

When initiation takes place with the switches in the positions set out above the following occurs:

- Mode 2. A special menu to update the software is shown on the screens.
- Mode 3. All stored channels are deleted directly. A message about deletion is shown on the screens followed by a menu to restore the channels.
- Mode 4. The receiver switch the signal standard from either PAL to NTSC depended on the original setting. Each time the system is restarted (ignition off and on again) or when the reset button is used, the

TV receiver switches between PAL or NTSC. The screens can handle both types of standard signals so that no difference in image is seen.

HINT: If the customer comes in with his/her vehicle and complains about one of the following, the position of the switches, as set out above must be checked. Normally these should always be set in Normal mode.

- a software update menu is always shown on the screens when showing the TV.
- the stored TV channels are always deleted and a message is shown.

ANTENNAS FOR DIGITAL TV RECEIVER

Fig. 259: Identifying Antenna For Digital TV Receiver
Courtesy of VOLVO CARS CORPORATION

The two antennas receive the transmitted digital TV signals and send these to the digital TV receiver. The antennas are voltage fed and ground from the TV receiver. A supply voltage of approx. 5 V is fed via the antenna cable's conductor and is ground via the cable's screen.

On each antenna, under the cover, is a status LED that lights when the digital TV receiver is on and the antenna is OK. If the system is on and the LED is not lit, there is either a fault on the antenna, its cables or the supply from the TV receiver.

The antennas are installed underneath the upper side corners on the rear bumpers.

DIAGNOSTIC FUNCTIONS

For diagnostics the Rear seat entertainment module (RSE)/DVD-player has a basic internal system check and a start-up procedure for the screens.

The control module is not connected to the vehicle's other CAN networks. This means for example that **no** diagnostic trouble codes (DTCs) can be read from the control module. All fault tracing must therefore be carried out via symptom fault tracing.

The following is information that may facilitate when fault tracing in the system.

When the ignition is switched on the Rear seat entertainment module (RSE) performs a basic internal system check and starts the start-up procedure with the screens.

If the time from when the ignition is switched on until the system is in standby mode (only the illuminated POWER button is lit) is longer than normal, this indicates a communication fault with the screens.

The start-up times, see: **SYSTEM START-UP PROCEDURE**

Causes of a long start-up time can be:

- No supply voltage and ground to the screen
- Damaged wake-up signal cable.
- Damaged cables for the internal CAN network (no communication can take place). In connector D on the Rear seat entertainment module (RSE)/DVD-player the CAN network is strapped for the *right-hand screen* . The strap is used to support the future expansion of the system with additional devices. If connector D has been damaged, has become dislodged or for some reason there is no connection between both ends of the strap on the CAN cables, it will not be possible to establish communication.

Switch on the system using the POWER button on the DVD player

If one of the screens does not start when the system is switched on, when the start-up procedure has elapsed over the normal time (without fault), and only the POWER lamp on the control module/DVD player is lit, this indicates a fault with the actual screen or its cables between the screen and the circuit board.

When communication with the control modules/DVD player in this case is okay, both these screens' circuit boards behind the actual screens are OK.

The functionality of the circuit boards can also be checked by switch on the system and checking whether the IR lamps in the bottom of the screen are slightly illuminated.

The IR-lights are lit for about 2 minutes after the system is switched on or when sound is played from a selected audio source.

Switch on the system using the remote control

If the system is switched on using the remote control aimed towards the right-hand screen, when the voltage supply and ground to the screen are fully functional but for example there is no CAN-communication with the Rear seat entertainment module (RSE)/DVD-player, the screen will be lit and work in LOCAL mode. It will then be possible to show the menus and to adjust the sound and brightness settings.

This can be misinterpreted as the function is OK. However no image will be shown on screen if, for example, you play a DVD disc or watch the TV. The system will be switched on and the left-hand screen will start. This is because the cables for the IR signals do not go via the CAN network, but go directly to the DVD player and are interpreted.

If the screen works in LOCAL mode this indicates that the voltage supply and ground to the screen's circuit board are OK.

FUNCTION

REAR SEAT ENTERTAINMENT MODULE (RSE)

Fig. 260: Identifying Rear Seat Entertainment Network
Courtesy of VOLVO CARS CORPORATION

HINT: AUX-input (16/123.2) in XC90 has number 17/40.1.

NOTE: There may be a slight delay between selecting a DVD function with the remote control and activation of the DVD player function. A message will appear on the screen to confirm that the DVD function was selected. Display of 'Not permitted' indicates that the DVD player is still processing a previously selected function.

The rear seat entertainment system is power fed and controlled by the Rear seat entertainment module (RSE) (16/109). The control module also includes the system's DVD player.

The system is powered via X-feed and directly from the battery. If the system is operating when the ignition is switched of, a question will appear on the screens as to whether continued play is permitted.

If the user answers YES, the system will continuing playing another 10 minutes. The system will then shut down. If there is no response to the question, the system will shut down after 1 minute. As a means of safeguarding the battery, play time cannot be extended unless the ignition is switched on again.

All buttons will light for approximately 5 seconds when attempting to start the system using the POWER button on the DVD player in this mode, they will then go out. Accordingly, the system is not permitted to start before the ignition has been switched on again.

When the ignition is switched on the Rear seat entertainment module (RSE) performs a basic internal system check and starts the start-up procedure with the screens.

For further information, see: **SYSTEM START-UP PROCEDURE**

If the system is to be switched on using the remote control, the ignition must be switched on and the remote control must be pointed at one of the screens before any buttons are depressed, the receiver for the signals from the remote control is located on the lower edge of the screens.

When the remote control is aimed at a screen (16/81A, B) and a function key is pressed in, the Rear seat entertainment module (RSE) identifies the selected screen and executes the command that the remote control sent out.

If, for example, you press a menu selection button, a menu opens on the screen at which the remote control was aimed. The possible selections are described below:

- Independent shifting of three audio/video inputs (DVD, TV (if installed) and AUX).
- Image adjustment (image color, brightness, contrast and aspect ratio).
- Audio settings (bass, treble and volume).
- Language selection for on-screen instructions.
- Switch individual screens ON/OFF.
- Service menu to reach settings such as selection of region code, TV receiver, etc.

Rear seat entertainment module (RSE) also decides which media source that has been linked to the selected screen and transmits command in a suitable protocol.

If, for example, the left screen is set for DVD-playback and an infrared play command is detected at the left screen, the message is received, saved and forwarded to the DVD-player (16/109) in the DVD-player's infrared protocol.

A fixed memory saves the displayed instruction language used and the current audio and video settings for the respective output channel. These settings are loaded upon start-up with the exception of volume level, which is set to low as standard.

When a DVD disc is inserted in the opening DVD playback starts automatically if the DVD disc does not have a disc menu.

DVD playback can resume from a paused position, for example, if the ignition was switched off when watching a movie. In this case playback continues from the last position when the ignition is switched on again. The audio and video signals are fed out from the DVD player from the connection block (ISO connection) at the rear of the device.

SYSTEM START-UP PROCEDURE

See: **SYSTEM START-UP PROCEDURE**

PLAYBACK OF AUDIO IN THE VEHICLE'S FIXED AUDIO SYSTEM

Fig. 261: Identifying Rear Seat Entertainment Network
Courtesy of VOLVO CARS CORPORATION

HINT: AUX-input (16/123.2) in XC90 has number 17/40.1.

In order to playback audio from the DVD player using the vehicle's ordinary audio system the Rear seat entertainment module (RSE)/DVD player is connected to the AUX input on the Integrated Audio Module (IAM).

Audio from the DVD-player or AUX-input can be selected as audio source on Integrated Audio Module (IAM) by selecting input signal "AUX" in the audio system's menu system.

When Rear seat entertainment module (RSE)/DVD-player plays a disc, the audio is automatically sent out on the outputs to the Integrated Audio Module (IAM). But no sound will be heard in the speakers until "AUX" has been selected as the audio source.

NOTE: If an audio source is connected to the AUX input's 3.5 mm stereo connection, the audio signals from the Rear seat entertainment module (RSE)/DVD player to the Integrated Audio Module (IAM) are disconnected.

INFRARED (IR) CONTROL

Fig. 262: Remote Control Signal With Infrared Light
Courtesy of VOLVO CARS CORPORATION

There is an infrared receiver (IR receiver) in each screen. The IR receivers are directly connected to the Rear seat entertainment module (RSE) (16/109) and are activated when the Rear seat entertainment module (RSE) is voltage fed. When a button is pressed on the remote control a signal is sent out with infrared light (IR). This signal has a different coding depending on the button pressed. The IR signal is received by the IR receiver under the screen (16/81A, B) on each head restraint and is forwarded to the Rear seat entertainment module (RSE) for processing.

The remote control can be used to switch between different audio and/or video inputs in the system:

- DVD player, audio/video
- AV-panel, audio or audio/video
- Audio/video from a TV receiver (if installed) to one or both screens.

Selection is performed by aiming the remote control at the screen where the command is to be executed.

Depending on which of the two screens that received the command, the Rear seat entertainment module (RSE) will select AV- or audio source for that screen. Then the remote control can be aimed at the other screen to select source for that screen.

HEADPHONES

Fig. 263: Identifying Signal to Headphones
Courtesy of VOLVO CARS CORPORATION

Two pairs of headphones are supplied with the system as standard. The transfer of sound between the screen and the wireless headphones takes place using an infrared signal (IR). Any number of headphones can be connected provided that they are within the working range of the IR transmitters.

There must be a clear path between the transmitter on the lower edge of the screen and the receiver on the side of the headphones. If the path is blocked the signals may be disrupted and the audio quality impaired.

The headphones are switched on with the switch located on the side. The headphones switch off automatically if no IR signal is received for 3-4 minutes.

The headphones also have a button to set which audio channel to listen to. Channel A or B can be selected. Channel A is always transmitted from the left screen and channel B is always transmitted from the right screen.

NOTE: The audio signal from the screens to the headphones has a fixed sound level. This means the headphone volume can only be adjusted using the knob on the headphones.

SHOWING TV PROGRAMS

Fig. 264: Identifying Rear Seat Entertainment Network
Courtesy of VOLVO CARS CORPORATION

When the ignition is switched on the Rear seat entertainment module (RSE) performs a basic internal system check and starts the start-up procedure with the screens. At the same time a wake-up signal is sent to the TV receiver and the TV receiver's green status LED comes on.

When the start-up procedure for the screens has finished and the illuminated buttons on the DVD player, except the POWER button, have gone out the TV receiver's status LED also goes out.

When the system is switched on using e. g. the POWER button on the DVD player the status LED comes on.

When the remote control is directed towards a screen (16/81A, B) and the function button to select the signal source (DVD/AUX/TV) is pressed a menu is displayed. The TV receiver can be selected as the "source" from the menu. When the TV receiver is selected, the last tuned channel is shown. If no channel has been stored a channel menu is shown.

NOTE: **The direction of the antenna and the current reception conditions determine the image quality. If the image breaks up or freezes, if the audio stutters or if some channels disappear this is probably due to a weak antenna signal. The signal was affected among others by the lay of the land, weather conditions and the position of the vehicle in relation to the TV transmitter, consequently the problem can appear in connection with movements, time of the year, weather**

conditions.

IDENTIFICATION OF GENERATION

see **IDENTIFICATION OF GENERATION**

ACCESSORIES AND BODY, CAB

Miscellaneous - Design and Function

ACCESSORY ELECTRONIC MODULE (AEM) (2003-2012)

DESIGN

TIMER START OF THE ELECTRIC PARKING HEATER

Fig. 1: Electric Parking Heater Timer Control And Module
Courtesy of VOLVO CARS CORPORATION

A timer control function can be connected to the electrical parking heater which is controlled via the accessory electronic module (AEM).

The system consists of:

- A relay for the electrical parking heater
- Wiring between the relay and accessory electronic module (AEM).

The relay is mounted on the engine block heater and controls the electrical parking heater and relay passenger compartment socket.

The relay acts as a switch and is supplied with power and controlled via the wiring from the accessory electronic module (AEM).

The relay is connected to the ground terminal in the engine compartment.

When post-installing the timer start system for the electrical parking heater the car must be configured using new software which is carried out via VIDA (Volvo scan tool).

There are diagnostics for the relay/control signal.

REMOTE CONTROLLED PARKING HEATER

There are two ways to remote control the parking heater. Via the mini-call system and via remote control. There are also two types of parking heater, an electrical parking heater and a gasoline parking heater. The type of heater to be activated via remote start must be preset in the car's driver information module (DIM).

Remote start using the remote control cannot be combined with remote start via the mini call system.

To use the remote start function for the electrical parking heater, the "Timer start of the electric parking heater" function must be installed.

Remote starting via the mini call system (certain markets only)

Fig. 2: Mini-Call Unit
Courtesy of VOLVO CARS CORPORATION

The mini-call unit is directly connected with voltage supply, ground connection as well as start/stop signal to the accessory electronic module (AEM).

The mini-call unit is continuously supplied with voltage via the accessory electronic module (AEM) since it must be active all the time to be able to receive start and stop signals.

The remote start system for the parking heater is remote controlled using a normal telephone via the existing mini call network which is available in certain markets.

When installing the remote start warning system the car must be configured using new software. Configuration is carried out via VIDA (Volvo scan tool).

There are diagnostics for the remote start system.

Remote start via the remote control

Fig. 3: Parking Heater Remote Control
Courtesy of VOLVO CARS CORPORATION

The remote start system starts and stops the parking heater via a remote control instead of via mini call.

The remote start system consists of a remote control and a receiver for the remote control as well as a contact relay mounted at the accessory electronic module (AEM). The receiver is supplied with voltage and connected to ground via a branching connection at the accessory electronic module (AEM).

Communication between receiver and the accessory electronic module (AEM) consists of a start or stop signal.

The remote start system with remote control is available as accessory for the accessory electronic module (AEM) for cars of later versions.

There are three LR03 (AAA) batteries in the remote control.

The remote control must be synchronized with the receiver.

When installing the remote start warning system the car must be configured using new software. Configuration is carried out via VIDA (Volvo scan tool).

ALARM SIGNAL OUTPUTS

An external (aftermarket) alarm unit can be connected to the accessory electronic module (AEM). The system consists of four output signals that via a cable harness can be used as input signals in the external alarm system. The accessory electronic module (AEM) uses the existing CAN-network to receive/transmit signals that describe the car's alarm, key, and door status.

When installing an after market alarm system the car must be configured using new software. Configuration is carried out via VIDA (Volvo scan tool).

There are diagnostics for the alarm signal outputs.

TELEMUTE FUNCTION FOR NON-INTEGRATED MOBILE PHONES

With the telemute function, the audio module (AUM)/ audio control module (AUD), is muted when the cell

phone rings.

The design consists of a signal input and a signal output. The input signal is digital (0V/12V) and the output signal is a Controller area network (CAN) communication.

When post-installing the hands free unit the car must be configured using new software. Configuration is carried out via VIDA (Volvo scan tool).

There are diagnostics for the telemute function.

AFTERMARKET RADIO UNIT

The design consists of a signal input and four signal outputs on the accessory electronic module (AEM).

The input signal is an analogue +12V mute signal, from either the reverse warning system or the non-integrated hands free system.

Two output signal are pulse width modulated signals for the lighting rheostat signal position and the speed sensitive volume signal.

One output signal is a digital 12V mute signal to the radio unit.

One output signal is a +30 supply for an external aerial amplifier.

When installing an after market radio unit, the car must be configured using new software. Configuration is carried out via VIDA (Volvo scan tool).

Information regarding which production plant a car is manufactured in can be found in the VIN number. The seventh position from the right in the VIN specifies the production plant.

There are diagnostics for the system.

SIGNAL OUTPUT FOR RTI (ROAD TRAFFIC INFORMATION) (JAPAN ONLY)

The signal output consists of four output signals of which one is a pulsed speed signal (0V/12V), one for the brightness for the display lighting and one for indicating that reverse gear has been engaged.

The fourth signal is to deploy a relay which then controls the power supply to the navigation system.

When post-installing the RTI (Japan only) the car must be configured using new software. Configuration is carried out via VIDA (Volvo scan tool).

There are diagnostics for the signal outputs.

DIAGNOSTIC FUNCTIONS

GENERAL INFORMATION

The accessory electronic module (AEM) has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the accessory electronic module (AEM) detects a fault. This control module can store up to 6 diagnostic trouble codes (DTCs), the 3 first and the 3 latest.

Should a fault disappear for any reason after being permanently stored in the control module as a diagnostic trouble code (DTC), the information remains stored in the memory.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function. The diagnostic system in the accessory electronic module (AEM) can identify 32 different faults in form of diagnostic trouble codes.

This function can also be used to read off whether the fault is still present (permanent) or whether it has now ceased (intermittent) after the diagnostic trouble code (DTC) has been stored.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF INPUT AND OUTPUT SIGNALS

This function can be used to continuously read off the values and status for the accessory electronic module (AEM) input and output signals.

The following parameters can be read off:

- Voltage supply to the accessory electronic module (AEM)
- Rheostat signal, the strength is given as a percentage
- Speed signal, given as a frequency where 512 is the highest frequency
- Voltage level of the signal to the relay, engine block heater
- Voltage level of the signal to the remote start module
- Voltage supply to the remote start unit
- Voltage level of alarm signals P0, P1, S0 and S1
- Voltage level of the signal to telemute
- Voltage level of the signal from telemute
- Power supply to the aerial amplifier.

ACTIVATING COMPONENTS AND FUNCTIONS

This function can be used to activate components/functions which affect the accessory electronic module (AEM) outputs.

The following components can be activated:

- Start signal to the remote start unit
- Speed signal, simulates a change in speed from 0 km/h to 255 km/h in stages of 5 km/h
- Rheostat signal, simulates a change in light from 0% to 100% and then back to 0% in stages of 5%
- Telemute signal which simulates the phone muting the radio.

READING OFF THE CONTROL MODULE IDENTIFICATION

The diagnostic tool identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N
- start address CAN configuration.

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

When installing or replacing the accessory electronic module (AEM) the software must be downloaded to the control module. The software for the accessory electronic module (AEM) must be downloaded first. Then the software for the connected accessories must be downloaded.

When ordering software, the hardware and the software in the car is compared to the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

FUNCTION

STARTING THE PARKING HEATER VIA THE TIMER

Fig. 4: Starting Parking Heater Via Timer
Courtesy of VOLVO CARS CORPORATION

The left control lever controls the start timer for the parking heater. No other timer is required when setting the timer control. The control lever is directly connected to the steering wheel module (SWM) (3/130) which sends a signal via the CAN-net to the central electronic module (CEM), which in turn sends the signal on to the accessory electronic module (AEM) (4/78) when it is time to start the electric heater.

The start timer functions on either the electric or fuel-driven parking heater (not XC90). The accessory electronic module (AEM) is not involved when the fuel-driven parking heater is selected. The heater to be used is selected in the driver information module (DIM) (5/1).

It is also possible to combine this function with the remote start function.

REMOTE CONTROLLED PARKING HEATER

Remote starting via the mini call system (certain markets only)

Fig. 5: Remote Controlled Parking Heater Function
Courtesy of VOLVO CARS CORPORATION

The remote controlled system for the parking heater functions as follows. The mini call unit receives a signal from the mini call network to start the electrical parking heater or the fuel driven parking heater either directly or using the timer in the car.

Electrical parking heater

A signal is sent via the mini-call unit to the accessory electronic module (AEM) (4/78) to start the electric parking heater. The accessory electronic module (AEM) then sends a signal via the CAN-net to the central electronic module (CEM) (4/56). The central electronic module (CEM) then sends back a signal via the CAN-net to the accessory electronic module (AEM), which then controls the relay for the parking heater.

Fuel-driven parking heater

A signal is sent via the mini-call unit to the accessory electronic module (AEM) (4/78) to start the gasoline driven parking heater.

The accessory electronic module (AEM) then sends a signal via the CAN-net to the central electronic module (CEM) (4/56), which in turn starts the parking heater.

Selection of the type of parking heater is performed in the driver information module (DIM) (5/1).

The remote start function is dependent on good reception/coverage of the mini call network in order to operate satisfactorily.

Remote start via the remote control

Fig. 6: Remote Controlled Parking Heater Function
Courtesy of VOLVO CARS CORPORATION

The remote start system for the parking heater via remote control functions in the same way as the mini call system. However, the system does not use the mini call network.

The remote control sends a radio signal (FM) to the receiver. In turn, the receiver sends a start/stop signal to the accessory electronic module (AEM) (4/78).

The range of the remote control is approximately 400 meters but varies depending on the other conditions.

ALARM SIGNAL OUTPUTS

Fig. 7: Alarm Signal Outputs
Courtesy of VOLVO CARS CORPORATION

Output signals from the accessory electronic module (AEM) (4/78) are used when installing an after market alarm unit.

Access is available to signals indicating:

- the alarm status of the car
- the door status of the car
- the key status.

In this case the accessory electronic module (AEM) functions as a port between the car's CAN-net and the external alarm unit.

TELEMUTE FUNCTION FOR MOBILE TELEPHONES

Fig. 8: Telemute Function For Mobile Telephones
Courtesy of VOLVO CARS CORPORATION

In case of phone calls, the accessory electronic module (AEM) (4/78) receives an input signal from the aftermarket hands-free unit and transmits it on the CAN-net to the audio module (AUM) (16/1) (audio control module (AUD) in XC90). The audio module (AUM)/ audio control module (AUD) lowers the volume in the sound unit's speakers when the aftermarket hands-free unit is used.

The telemute function is available as an accessory for the accessory electronic module (AEM).

USING AN AFTER MARKET RADIO UNIT

Fig. 9: Using An After Market Radio Unit
Courtesy of VOLVO CARS CORPORATION

The accessory electronic module (AEM) (4/78) makes it possible to automatically control the telemute function, display lighting and speed-adapted volume control when using an aftermarket radio unit. This is on the condition that the aftermarket radio unit supports these functions. The accessory electronic module (AEM) receives a speed signal (volume adaptation) via the CAN-net and brightness of the display lighting via rheostat from the central electronic module (CEM) (4/56).

The accessory electronic module (AEM) also receives a mute signal from the reverse warning system and external hands-free unit and transmits it on to the radio unit.

SIGNAL OUTPUT FOR RTI (ROAD TRAFFIC INFORMATION) (JAPAN ONLY)

Fig. 10: Signal Output For RTI (Road Traffic Information) (Japan Only)
Courtesy of VOLVO CARS CORPORATION

The road and traffic information system, RTI in Japan, uses directly connected input signals from the accessory electronic module (AEM) (4/78) for processing of information.

The accessory electronic module (AEM) sends four signals to the RTI-system. Two of the signals are display lighting and reverse gear signal to the navigation unit, and the third is a speed signal. The fourth signal is a relay control for voltage supply.

The brightness of the display lighting, vehicle speed signal, and the reverse gear signal comes from the central electronic module (CEM) (4/56) via the CAN-net.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 11: Accessory Electronic Module
Courtesy of VOLVO CARS CORPORATION

The function of the accessory electronic module (AEM) is to allow certain accessories to exchange information with the car's controller area network. This exchange of information means that accessories can be installed with greater functionality and higher quality. The accessory electronic module (AEM) manages the following functions:

- Reverse warning system
- Relay for the electrical engine block heater
- Remote start for the parking heater
- External aftermarket alarm
- Aftermarket radio unit
- Signals for RTI (road traffic information) for Japan

- Tele-mute for non-integrated carphones.

The functions managed by the accessory electronic module (AEM) may vary between different car models.

The accessory electronic module (AEM) is an accessory and is only available for order and installation as an after market item.

Information regarding which production plant a car is manufactured in can be found in the VIN number. The seventh position from the right in the VIN specifies the production plant.

Information regarding which production plant a car is manufactured in can be found in the VIN number. The seventh position from the right in the VIN specifies the production plant.

The control module is installed in the cargo compartment of the car behind the side panel at the right-hand wheel arch.

After installation the accessory electronic module (AEM) is configured using software. Configuration is carried out via VIDA (Volvo scan tool).

The control module communicates with directly connected components, and via a Controller area network (CAN).

One of the main purposes of the control module is to function as an interface between accessories, which are not prepared for Controller area network (CAN) communication, and the Control area network (CAN) of the car and its functions.

The control module checks activations and input and output signals via an integrated diagnostic system. A diagnostic trouble code (DTC) is stored if the control module detects a fault. Any diagnostic trouble codes (DTCs) and stored in the control module memory and information can be read out using VIDA (Volvo scan tool).

SIGNALS

The table below summarizes the input and output signals to and from the accessory electronic module (AEM) (4/78). The signal types are divided into directly connected signals and Controller area network (CAN) communication. The following illustration displays the same information with the Volvo component designations.

NOTE: The signals are only available for installed accessories.

Input signals	Output signals
Directly connected: • The reverse warning system control module transmits a buzzer signal (mute signal) • Remote start module (mini call, remote	**Directly connected:** • Four signals for RTI (road traffic information) for Japan: • Speed

control) for remote starting the parking heater (start/stop signal) • The tele-mute signal from after market hands free units to the carphone to mute the volume on the audio module (AUM) (AUD) or after market radio unit.	• Reverse gear indication • Lighting signal • X-supply to the relay. • Parking assistance module (PAM) (voltage and ground terminal) • Start for the parking heater consisting of +12V to the relay for the electrical parking heater • External alarm unit (trigger signal/power supply) • Signal for integrating an after market radio unit (tele-mute signal, speed signal, rheostat signal and controlled power supply to the external antenna amplifier) • Tele-mute signal from an after market handsfree unit to an after market radio unit • Mini call unit for remote start, supply and ground terminal connection.

Via Controller Area Network (CAN):
• Central electronic module (CEM) (4/56):
  • Start and stop signal, to control the relay for the electrical parking heater
  • Reverse gear indication to start the reverse warning system
  • Reverse gear indication, for the RTI (road traffic information) system (Japan)
  • Vehicle speed signal, used by after market radio units and the traffic information system, RTI for Japan
  • Alarm status, used by the accessory electronic module (AEM) controlled external alarm
  • Light position, indicates parking lamps, low and full beam. Used by RTI (road traffic information) for Japan for the background lighting of the navigation display
  • Indication to not start the reverse warning system when a trailer is connected. Activated by switching on the turn signal lamps.
	Via Controller Area Network (CAN):
	• Central electronic module (CEM) (4/56):
	  • Remote start to activate the parking heater.
	• Audio module (AUM) (16/1):
	  • Tele-mute signal
	  • Reverse warning signal.

• Audio module (AUM) (16/1): • Indicates the brightness of the background lighting.	

Fig. 12: AEM Flow Chart
Courtesy of VOLVO CARS CORPORATION

ACCESSORY USB UNIT (AUU) (2007-2010)

DESIGN

CONTROL MODULE

Fig. 13: Accessory USB Unit (AUU)
Courtesy of VOLVO CARS CORPORATION

The accessory USB unit (AUU) is designed to serve as an interface between the vehicle infotainment system and external USB and iPod devices.

The accessory USB unit (AUU) has a directly connected USB port and supports the standard for removable media on USB 2.0.

The accessory USB unit (AUU) receives input signals from the infotainment control module (ICM) via the MOST network. The current status appears on the Infotainment Control Module (ICM) display.

All input and output signals from the control module travel via the MOST network.

The Accessory USB unit (AUU) is located in the tunnel console between the seats.

When replacing the control module reprogramming is required.

The control module can be diagnosed.

DIAGNOSTIC FUNCTIONS.

GENERAL INFORMATION

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault.

There are two diagnostic trouble codes (DTCs) for the Accessory USB unit (AUU). A fault that was detected during the last driving cycle is defined as permanent. Other faults that are detected are defined as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function. Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF THE CONTROL MODULE IDENTIFICATION

The diagnostic tool identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N.

READING OFF EXTENDED FAULT-TRACING INFORMATION

This function can be used to read out parameters, identify status and counts stored at the same time as a diagnostic trouble code (known as frozen values).

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the accessory USB unit (AUU). When software is ordered the software and hardware of the vehicle are compared with Volvo's central database. If the comparison corresponds then the software is downloaded into the control module.

If the comparison between the car and Volvo's central database does not correspond, the database is updated with the vehicle's configuration. When this is complete, new software is downloaded.

The Accessory USB unit (AUU) is located in the tunnel console between the seats.

Select the MOST network for a total download of software to the vehicle.

FUNCTION

PLAYING STORED MEDIA

Fig. 14: Media Network Components
Courtesy of VOLVO CARS CORPORATION

The task of the Accessory USB unit (AUU) is to manage playback of media that is stored on the external USB memory and the iPod player.

The Accessory USB unit (AUU) supports media formats:

- mp3
- wav
- wma

The accessory USB unit (AUU) (4/124) is controlled via the buttons on the center console. Signals indicate when the user has pressed the Play or Stop button.

The accessory USB unit (AUU) communicates with the infotainment control module (ICM) (16/94) via the MOST network. The infotainment control module (ICM) then uses the MOST network to send the signals on to the integrated audio module (IAM) (16/1) or the audio module (AUD) (16/105) depending on vehicle configuration.

The accessory USB unit (AUU) has functions for:

- next track/previous track
- fast forward/rewind
- random playback (Random)
- system search (scan)

Any stored text information is also sent via the MOST network to the infotainment control module (ICM) display, where it is displayed.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 15: View Of Accessory USB Unit (AUU)
Courtesy of VOLVO CARS CORPORATION

The accessory USB unit (AUU) is designed to serve as an interface between the vehicle's infotainment system and external USB and iPod devices that support the standard for removable media on USB 2.0.

Examples of USB/iPod devices that support the standard for removable media on USB and 2.0 are:

- Cameras
- MP3 players
- Handheld computers
- Portable USB drives
- iPod G4 from version 3.1.1
- iPod G5 from version 1.2.1
- iPod mini from version 1.4.1
- iPod nano from version 1.1
- iPod Video from version 1.1

The Accessory USB unit (AUU)is located in the tunnel console between the seats and the associated USB port is located either in the glove compartment or in the tunnel tray.

The accessory USB unit (AUU) has serial optic communication with components on the MOST network. All communication with the accessory USB unit (AUU) is handled via the infotainment control module (ICM).

In order to function in the MOST network, the infotainment control module (ICM) checks that the accessory USB unit (AUU) has a correct serial number. If the number is incorrect, the accessory USB unit (AUU) does not work.

The accessory USB unit (AUU) checks executed activations and input/output signals via its integrated

diagnostics. If the control module detects a fault, a diagnostic trouble code is generated. Any diagnostic trouble codes are stored in the control module memory. The information can be read via the data link connector in the vehicle.

SIGNALS

The table below summarizes the input signals to and output signals from the accessory USB unit (AUU). The signal types are divided into directly connected signals, serial communication and MOST communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: • External USB device (for example mp3 player and iPod devices)	**Directly connected:** • External USB device (for example mp3 player and iPod devices)
Via MOST communication: • Infotainment control module (ICM) (16/94)	**Via MOST communication:** • Infotainment control module (ICM) (16/94)

Fig. 16: Volvo Component Designations
Courtesy of VOLVO CARS CORPORATION

ACTIVE ON DEMAND COUPLING (AOC) (2003-2004)

DESIGN

CONTROL MODULE

Fig. 17: Active On Demand Coupling Control Module
Courtesy of VOLVO CARS CORPORATION

The differential electronic module (DEM) is secured directly to the coupling unit housing and forms a single unit with the axial solenoid. The axial solenoid controls the control valve.

The differential electronic module (DEM) receives signals from the engine control module (ECM), the central electronic module (CEM) and the brake control module (BCM) via the high speed side of the control area network (CAN). The differential electronic module (DEM) uses these signals to determine the oil pressure required for the multi-plate clutch in the coupling unit. The oil pressure for the multi-plate clutch determines the amount of torque which can be transferred to the rear wheels.

Four wheel drive is not available if there is a fault in the differential electronic module (DEM).

OIL PRESSURE AND TEMPERATURE SENSOR

Fig. 18: Identifying Oil Pressure And Temperature Sensor
Courtesy of VOLVO CARS CORPORATION

The oil pressure and temperature sensor in the clutch unit are close to the axial solenoid in the housing for the differential control module (DEM). The sensor is flushed with hydraulic fluid. The sensor gauges the temperature and pressure of the hydraulic fluid (measurement range 0-4 MPa). The sensor transmits signals about temperature and pressure to the control module. The control module uses the temperature and pressure signals to adapt the function of the system, changing the temperature, and therefore the viscosity, of the fluid as required.

If the temperature of the fluid exceeds 100 °C there is no pressure in the coupling and all wheel drive is disengaged. When the temperature falls below 100 °C the coupling is pressurized again. If the oil pressure exceeds 7.4 MPa, the safety valve in the coupling opens. The coupling is pressurized again when the oil pressure drops below 7.4 MPa.

Four wheel drive is not available if there is a fault in the pressure and/or temperature sensor.

There are diagnostics for the oil pressure and temperature sensor.

CONTROL VALVE/AXIAL SOLENOID

Fig. 19: Control Valve/Axial Solenoid
Courtesy of VOLVO CARS CORPORATION

The control valve/axial solenoid are in the coupling unit for the active on demand coupling (AOC).

The axial solenoid receives a constant pulse width modulated (PWM) signal from the control module. The control signal from the control module is used by the solenoid to change the position of the control valve. This regulates the pressure to the operating piston in the multi-plate clutch.

Four wheel drive is disabled if there is a fault in the control valve/axial solenoid.

There are diagnostics for the control valve/axial solenoid.

ELECTRICAL FEED PUMP

Fig. 20: Electrical Feed Pump
Courtesy of VOLVO CARS CORPORATION

The electrical feed pump is integrated in the coupling unit and is powered by the differential electronic module (DEM). When the engine is started and exceeds 400 RPM, the electrical feed pump receives power from the control unit.

The feed pump pumps oil to the annular pistons, whose rollers move into contact with the cam disc. At the same time the oil flows to the operating piston, so that the play in the multi-plate clutch unit is eliminated. The coupling is then able to react rapidly and regulate as required.

Four wheel drive is disengaged if there is a fault in the feed pump.

There are diagnostics for the feed pump.

DIAGNOSTIC FUNCTIONS

GENERAL INFORMATION

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. Should a fault disappear for any reason after being permanently stored in the control module as a diagnostic trouble code (DTC), the information remains stored in the control module.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF INPUT AND OUTPUT SIGNALS

This function can be used to continuously read off the status of the control module's input and output signals.

For further information about parameters, see **DESCRIPTION OF PARAMETERS**

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N.

DESCRIPTION OF PARAMETERS

This parameter description contain both a description for Differential Electronic Module (DEM) generation 3 and for generation 4. Generation 3 is presented first, and then generation 4.

PARAMETERS, STATUS

NOTE: The parameters that can be read off are determined by the systems with which the car is equipped.

ENGINE STARTED

The value indicates whether the pump motor is started.

YES = Engine started.

NO = Engine not started.

PARAMETERS, VALUE

DIFFERENTIAL ELECTRONIC MODULE (DEM), VOLTAGE

The value indicates the voltage in the control module.

Measurement range: 0-24 V

CENTRAL ELECTRONIC MODULE (CEM), VOLTAGE

The value indicates the voltage over the Central Electronic Module (CEM).

The control module transmits the signal on the controller area network (CAN) and the Differential Electronic Module (DEM) uses the signal to diagnose the power supply.

Measurement range: 5-30 V

OIL TEMPERATURE

The value shows the oil temperature in the clutch for all-wheel-drive.

Measurement range: -128 °C to +127 °C

OIL PRESSURE

The value shows the oil pressure in the clutch for all-wheel-drive.

Measurement range: 0-4 MPa

SOLENOID, CURRENT

The value indicates the current through the control solenoid for all-wheel-drive.

Measurement range: 0-4095 mA

PUMP, CURRENT

The value indicates the supply through the hydraulic feed pump.

Measurement range: 0-8191 mA

WHEEL SPEED

The value indicates wheel speed.

The Brake Control Module (BCM) transmits the speed signal on the controller area network (CAN) and the Differential Electronic Module (DEM) uses the signal to engage all-wheel drive.

Measurement range: 0 - 250 km/h.

NUMBER OF DETECTED ERRORS

The value indicates the number of detections of incorrect all-wheel-drive engagements.

The Differential electronic module (DEM) has an internal counter that counts up each time an incorrect engagement of all-wheel-drive is detected. The Differential electronic module (DEM) can only detect one incorrect engagement per operating cycle.

Measurement range: 0-255 times

PARAMETERS

These parameters apply to Differential Electronic Module (DEM) generation 4.

PARAMETERS, STATUS

NOTE: The parameters that can be read off are determined by the systems with which the car is equipped.

BRAKE PEDAL

The value indicates the status of the stop lamp switch. The engine control module (ECM) sends a signal on the controller area network (CAN) about the position of the stop lamp switch: activated or not activated.

Activated = brake light switch actuated.

Not activated = stop lamp switch unaffected.

PARKING BRAKE

The value indicates the position of the parking brake.

Activated = Parking brake applied.

Not activated = Parking brake not applied.

PARAMETERS, VALUE

POWER SUPPLY, DIFFERENTIAL ELECTRONIC MODULE (DEM)

The value indicates the power supply to the Differential Electronic Module (DEM).

Measurement range: 0 - 25.5 V.

Normal range: 12.0 - 14.5 V.

POWER SUPPLY, PUMP MOTOR

The value indicates the supply through the electrically driven feed pump.

Measurement range 0 - 8191 mA.

POWER SUPPLY, PRESSURE REDUCING VALVE

The value displays the current through the pressure reducing valve.

Measurement range 0 - 4095 mA.

WHEEL SPEED

Shows the wheel speed on all four wheels.

The brake control module (BCM) transmits the vehicle speed signal on the controller area network (CAN) and the differential electronic module (DEM) uses the signal to control four wheel drive.

Measurement range: 0 - 255 km/h.

ECU-TEMPERATURE

The value shows the temperature in Differential electronic module (DEM). The temperature sensor is located on the circuit board.

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software for the differential electronic module (DEM) can be downloaded. When ordering software, the hardware and the software in the car are compared to the data in the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

The control module is integrated in the coupling unit for the active on demand coupling (AOC). If the control module is replaced, the control valve/axial solenoid and oil pressure and temperature sensor must also be replaced.

FUNCTION

ELECTRONIC FUNCTION

Fig. 21: Active On Demand Coupling Electronic Function
Courtesy of VOLVO CARS CORPORATION

1. Oil pressure and temperature sensor
2. Differential electronic module (DEM)
3. Control valve/axial solenoid
4. Electrical feed pump.

The differential electronic module (DEM) is secured directly to the coupling unit and forms a single unit with the axial solenoid and control valve. The differential electronic module (DEM) receives signals from the engine control module (ECM) and the brake control module (BCM) via the control area network (CAN). The differential electronic module (DEM) uses the sensor signals to control the oil pressure to the multi-plate clutch by adjusting the axial solenoid. The axial solenoid regulates the control valve constantly using a pulse width modulation (PWM) signal. The oil pressure for the multi-plate clutch determines the amount of torque which can be transferred to the rear wheels.

NOTE: If the car has dynamic stability and traction control (DSTC), the required stability control is applied before four wheel drive.

Active On demand Coupling (AOC) has an oil pressure and temperature sensor, which gauge the prevailing temperature and pressure of the hydraulic fluid. The oil pressure and temperature sensor provide the differential electronic module (DEM) with information about the temperature and pressure. Four wheel drive is disengaged to protect the coupling unit from damage if the temperature becomes too high, above 97 °C. The coupling unit

is re-engaged at full function when the temperature falls below 93 °C.

MECHANICAL FUNCTION, OVERVIEW

5. Operating piston
6. Input shaft
7. Cam disc
8. Housing for the outer plates
9. Outer plates
10. Inner plates
11. Springs
12. Output shaft.

The gearbox transfers engine torque to the propeller shaft. The input shaft is separate from the output shaft. The

multi-plate clutch in the coupling must be engaged to transfer torque to the rear axle. The inner and outer wet multi-plate clutch are the transfer point between the input and output shafts.

The sinusoidal cam disc rotates at the same speed as the propeller shaft. The annular piston rollers act on the cam disc to press the annular piston in and out. This creates an oil pressure which affects the operating piston, which in term engages the multi-plate clutch unit.

HYDRAULIC FUNCTION, OVERVIEW (-2005)

12. Oil filter
13. Suction valves
14. Piston pump
15. Operating piston
16. Wet plate unit
17. Bearing
18. Springs.

The Active On demand Coupling (AOC) can be described as a hydraulic pump.

The basic pressure is generated by the electronic feed pump. This pressurizes the annular pistons with oil so that they are pressed against the cam disc via rollers. The annular piston generates a working pressure which is led to the operating piston via the pressure valve. This pressure creates a fixed connection between the input and output shafts. The maximum pressure is limited by the pressure limiting valve. The difference in speed between the input and output shafts is in proportion to the oil pressure fed to the annular pistons. A large difference between the input and output shafts results in high oil pressure to the annular pistons. If the input and output shafts are at the same speed, the oil pressure to the annular pistons is less. The oil pressure at the multi-plate clutch is regulated by the control valve. The axial solenoid controls the control valve. A closed control valve gives maximum pressure to the multi-plate clutch, resulting in maximum power gearbox. An open control valve gives minimum pressure to the multi-plate clutch, resulting in limited power gearbox.

The accumulator maintains the basic pressure in the system. The oil filter keeps the fluid clean by filtering dirt and small particles which could damage the system.

18. Springs.
19. Relief and by-pass valve

The Active On demand Coupling (AOC) can be described as a hydraulic pump.

The basic pressure is generated by the electronic feed pump. This pressurizes the annular pistons with oil so that they are pressed against the cam disc via rollers. The annular piston generates a working pressure which is led to the operating piston via the pressure valve. This pressure creates a fixed connection between the input and output shafts. The maximum pressure is limited by the pressure limiting valve. The difference in speed between the input and output shafts is in proportion to the oil pressure fed to the annular pistons. A large difference between the input and output shafts results in high oil pressure to the annular pistons. If the input and output shafts are at the same speed, the oil pressure to the annular pistons is less. The oil pressure at the multi-plate clutch is regulated by the control valve. The axial solenoid controls the control valve. A closed control valve gives maximum pressure to the multi-plate clutch, resulting in maximum power gearbox. An open control valve gives minimum pressure to the multi-plate clutch, resulting in limited power gearbox.

The accumulator maintains the basic pressure in the system. The oil filter keeps the fluid clean by filtering dirt and small particles which could damage the system.

Pretensioning

The function of the four-wheel drive system is based in there being a difference in speed between front and rear wheels. This difference in speed can affect traction performance in certain driving situations. The role of the pretensioning function is to improve traction performance, primarily in starting off from being stationary, without affecting other properties of the system to achieve this.

The pretensioning function has been achieved by replacing one of the AOC unit suction valves with a new combined relief and by-pass valve, extra oil ducts in the housing and adapted software in the differential electronic module (DEM).

As before, the electronic feed pump starts as soon as the engine has started. Running the pump at a higher speed than before generates increased oil flow. The increased oil flow combined with the new relief and by-pass valve results in a pressure increase that can work on the clutch discs. Greater engine torque can thereby be transferred to the rear axle. The pretensioning function is controlled by software so that it is only activated when necessary.

SYSTEM OVERVIEW

ACTIVE ON DEMAND COUPLING (AOC)

Fig. 25: Active On Demand Coupling
Courtesy of VOLVO CARS CORPORATION

The main role of Active On demand Coupling and the differential electronic module (DEM) is to regulate the four-wheel drive function, i. e. the distribution of drive between the front and rear axles. The system consists of a coupling combining mechanical, hydraulic and electronic sections. The coupling unit is on the rear axle, between the differential gear and the propeller shaft. The mechanical and hydraulic sections are driven by the rotation of the propeller shaft.

Active On demand Coupling (AOC) has the following characteristics:

- Permanent all wheel drive with electronic control of torque transfer
- Driving characteristics similar to all wheel drive
- Quicker reactions
- No wind-up during slow speed maneuvers and parking
- The system is not sensitive to differences between tires (when driving with a spare wheel for example)
- The system is not sensitive to being towed with one axle raised
- Unaffected by brake tests on a chassis dynamometer.

COUPLING UNIT AND CONTROL MODULE

Fig. 26: Coupling Unit And Control Module
Courtesy of VOLVO CARS CORPORATION

The hydraulic section consists of 1-5, the mechanical section consists of 6-10 and the electronic section consists of 11-13.

1. Pressure valves
2. Accumulator
3. Oil filter
4. Annular pistons
5. Control valve/axial solenoid
6. Input shaft
7. Inner and outer wet multi-plate clutch
8. Inner connection hub with sinusoidal cam disc
9. Rollers with annular pistons
10. Output shaft
11. Electrical feed pump

12. Differential electronic module (DEM)
13. Oil pressure and temperature sensor.

The differential electronic module (DEM) is integrated in the coupling unit.

The differential electronic module (DEM) communicates with other control modules using controller area network (CAN) communication.

There are internal diagnostics for the control module.

SIGNALS

The table below summarizes the input signals to and output signals from the differential electronic module (DEM). The following illustration displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: • **Oil pressure and temperature sensor** .	**Directly connected:** (power supply unless otherwise stated) • **Electrical feed pump** • **Axial solenoid** - pulse width modulated (PWM) signal.
Via Controller Area Network (CAN) communication: • **Central electronic module (CEM)** (4/56), status of the parking brake switch, ignition key position and back-up (reverse) signal • **Brake control module (BCM)** (4/16), the wheel speed from the wheel rotation sensor and the status signal (to open the coupling during stability control) • **Engine control module (ECM)** (4/46), provides data about engine speed (RPM), torque, accelerator pedal (AP) position and the status of the stop lamp switch.	**Via Controller Area Network (CAN) communication:** • **Brake control module (BCM)** (4/16), status of the coupling.

ADDITIONAL HEATER AND PARKING HEATER (COMBUSTION PREHEATER MODULE) (2003-2004)

ADDING ACCESSORIES AND REPLACING THE CONTROL MODULE

REPLACING THE CONTROL MODULE

New software cannot be downloaded into the combustion preheater module because it is not a CAN node. Software can be downloaded into the central electronic module to obtain a new function.

ADD ACCESSORIES

The following accessories can be ordered to add functions:

- Additional heater
- Parking heater
- Residual heater.

Heaters are factory installed from structure week 9850 inclusive and can also be ordered for older cars. When the parking heater function is added to a car, the software is downloaded into a varying number of control modules (depending on the structure week in which the car was built) as follows: The structure week in which the car was manufactured can be read off using VIDA - Vehicle communication.

When ordering software, the status of the software in the car is compared to the Volvo central database. If the

comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the latest information. When this is complete the software is downloaded.

DESIGN

PARKING HEATER

Fig. 28: Additional Heater And Parking Heater
Courtesy of VOLVO CARS CORPORATION

The start time for the heater is always programmed by selecting the desired parking function using the ring on the control stalk and entering the desired time by turning the ring and pressing the "reset" button. Direct start can also be used to start the heater.

The climate control module is activated when the engine coolant temperature (ECT) is > +20 °C. The blower fan starts and distributes the air in the passenger compartment.

Certain conditions must be met before the heater can start. These are:

- Quantity of fuel >4 liters
- No diagnostic trouble codes (DTCs) stored in the central electronic module that will prevent starting
- Airbag not deployed.

When the conditions are met, the heater glow plug is activated for 1 minute. If the voltage has dropped below 11.5 V, the climate control module is stopped. The heater and the climate control module are stopped if the voltage falls below 11.3 V. A message indicating low battery voltage is displayed in the combined instrument panel (driver information module). These voltage values apply even if the heater is operating normally.

To minimize the risk of the fuel pump for the heater failing due to lack of use, the central electronic module sends a signal every week to the combustion preheater module to activate the pump for approximately 1 second. This takes place when the ignition is switched off.

DIAGNOSTIC FUNCTIONS

GENERAL INFORMATION

Fig. 29: Additional Heater And Parking Heater (Combustion Preheater Module)
Courtesy of VOLVO CARS CORPORATION

The control module has a built-in diagnostic system, the Volvo on-board diagnostic (OBD) system. This system continuously monitors itself and the input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

If the control module detects a fault a diagnostic trouble code (DTC) list is sent from the additional heater module to the central electronic module. The heater can identify up to 25 faults.

The diagnostic trouble codes (DTC) are stored in the central electronic module. If for some reason a fault disappears after the diagnostic trouble code (DTC) has been permanently stored, information about the fault is stored in the central electronic module.

READING OFF THE VOLVO ON-BOARD DIAGNOSTIC (OBD) SYSTEM

Information about faults and other data can be read off using the VIDA PC connected to the data link connector (DLC). The VIDA PC communicates with the control module via a standardized interface.

VOLVO ON-BOARD DIAGNOSTIC (OBD) SYSTEM

With the VIDA PC it is possible to:

- read off and erase stored diagnostic trouble codes (DTCs)
- continuously monitor the values and status of the input and output signals for the signals
- activate certain functions
- read off the control module identification.

The following conditions must be met before the Volvo on-board diagnostic (OBD) system is activated:

- the ignition must be on
- the battery voltage must be normal.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function. The on-board diagnostic (OBD) system can identify 25 different faults in the form of diagnostic trouble codes (DTCs).

Diagnostic trouble codes (DTCs) can only be erased when all diagnostic trouble codes (DTCs) have been read at least once. Diagnostic trouble codes (DTCs) for the heater are stored in the central electronic module.

READING OFF INPUT AND OUTPUT SIGNALS

Using this function, the values and status of the control module input and output signals can be continuously read off.

The following parameters can be read off:

- failed start attempt, Heater
- successful start attempt, Heater
- overheating incidents, Heater
- engine coolant temperature, value
- battery voltage, value
- additional heater status, value
- Extended X-supply, status
- glow plug, status
- glow plug grade, value
- water pump, status
- combustion fan, actual value
- combustion fan, calculated value
- combustion fan PWM, value
- fuel pump frequency, value
- fuel level, status
- heater operation time, value

- supply voltage to components, status.

ACTIVATING COMPONENTS AND FUNCTIONS

With this function the components and functions in the additional heater system can be activated.

The following components can be activated:

- the additional heater
- the water pump
- the combustion fan
- the glow plug
- the fuel pump
- component supply voltage.

NOTE: It is important that only the ignition is on in order for the heater to start.

READING OFF THE CONTROL MODULE IDENTIFICATION

The control module can be identified by reading off a code from the control module memory.

The code contains information about the control module's:

- hardware P/N (control modules without software)
- hardware serial number (control modules without software)
- software P/N
- P/N diagnostic software.

FUNCTION

DESCRIPTION OF FUNCTION OF THE OPERATING STATUS OF THE HEATER

The heater can have a number of different statuses. Each status and what should occur in it is described below.

Operating status:	Description:
0: The heater has not started	Initialization of the heater control module (combustion preheater module)
1: The heater starts	Heater self test. The glow plug and the water pump is activated. The combustion fan then starts at low speed to ventilate the heater. This is to cool the glow plug so that the flame sensor does not detect light from the glow plug as a flame. The control module pulses the supply to the glow plug (pulse width modulation (PWM) signal).

	The glow plug is sufficiently warm after approximately 45 seconds to ignite the fuel. This whole process takes approximately 1 minute.
2: The heater starts and the fuel pump is active	The fuel pump starts and the speed of the combustion fan increases. The control module waits for a flame. The blower fan will now be running. This procedure takes a maximum of one minute.
3: The heater runs	A flame has been detected by the flame sensor and heats the heater. When the car is being driven the heater is stopped if the engine coolant temperature (ECT) exceeds a certain level. The heater is stopped by cutting the fuel supply. The combustion fan ventilates the heater when the flame has gone out. When the temperature falls below a certain level, the heater starts again. This means that the heater cycles between 2 temperature ranges.
4: The heater stops	The fuel pump stops, the flame is extinguished and the heater is ventilated.
5: The heater waits	Waiting for the engine coolant temperature (ECT) to fall low enough for the heater to start again.
6: The heater has stopped	The heater only has this status if a fault has occurred.
7: The flame is extinguished	The flame has gone out while the car is being driven.
8: Residual heat	If, when the outside temperature is low, the driver is in the car and turns on the heater, the water pump starts in order to heat the passenger compartment.
9: Fuel pump activated	Used in production.
10: Activating the fuel pump	Single pulses to the fuel pump are used to prevent the fuel pump sticking.

FUNCTIONS

Fig. 30: Additional Heater And Parking Heater
Courtesy of VOLVO CARS CORPORATION

The vehicle configuration can be read off to check what functions the car is equipped with. The following affect the function of the heater:

- Parking and additional heater function
- Parking heater or not (gasoline engines)
- Residual heater or not
- Electrical engine block heater (time controlled via the driver information module) or not.

FUEL DRIVEN PARKING HEATER

Fig. 31: Additional Heater And Parking Heater
Courtesy of VOLVO CARS CORPORATION

The user sets the desired start time using one of the two timer functions in the display on the combined instrument panel (driver information module) (5/1). The time is programmed by twisting the ring on the control stalk and by pressing the "reset" button for the desired time (timer 1, timer 2 or direct start). Direct start can also be used to start the heater.

The central electronic module (4/56) receives data about when the driver wants to drive from the control stalk module (steering wheel module) (3/130) and the combined instrument panel (driver information module).

The central electronic module calculates when the heater needs to start so that it is warm enough in relation to the outside temperature. Information about the temperature comes from the outside temperature sensor which is connected to the driver's or passenger door module.

The central electronic module calculates when the heater needs to start:

- The heater calculates when start is required (15-50 minutes before the intended departure at medium low temperatures between -10 °C and +15 °C)
- The run time of the heater is a maximum of 60 minutes at temperatures < -10 °C
- The running time of the heater is at least 15 minutes before the planned departure (Warm temperatures between +15 °C and +25 °C).

When the heater is started directly using the control stalk it runs until it is shut off or for a maximum of 60 minutes. The heater is on for 10 minutes after the set time to allow for the driver getting to the car late.

A text message is displayed in the driver information module when the heater is running.

ELECTRICAL HEATER WITH TIMER FUNCTION

Fig. 32: Electrical Heater With Timer Function
Courtesy of VOLVO CARS CORPORATION

The desired departure time is set using the control lever module (steering wheel module) (3/130).

The central electronic module (4/56) calculates when the heater should start. The heater starts 2 hours and 45 minutes before the set departure time, irrespective of the temperature. A text message is displayed in the driver information module (5/1) when the electrical heater is running.

The accessory electronic module (4/78) electrically controls when the heater should be switched on and off. The engine block heater must be connected to a wall socket. The accessory electronic module activates a relay which closes the switch for a heater element.

RESIDUAL HEATER

Fig. 33: Residual Heater
Courtesy of VOLVO CARS CORPORATION

This function can be ordered as an accessory.

The function is activated in the driver information module (5/1) using the control stalk (compare to the parking heater). Information about activation is sent to the central electronic module (4/56) and climate control module (3/112). The blower fan and damper settings are set by the climate control module. The central electronic module transmits data to the combustion preheater module (4/7) instructing it to activate the water pump.

When the residual heater is activated it will operate as long as the coolant temperature is above 30 °C or for a maximum of 20 minutes or until the function is switched off.

This function is used when the coolant is already warm. The coolant pump is started thereby circulating the coolant. The heat is distributed from the coolant to the passenger compartment unit in the climate control unit and on to the passenger compartment.

When the residual heater is running, the passenger compartment is heated by the climate control module controlling the fan and damper according to a customer parameter (Applies only to electronic climate control (ECC)). This parameter is used to set the distribution between the defroster and the floor. The normal setting is 30% defroster and 70% floor.

ADDITIONAL HEATER AND PARKING HEATER

Fig. 34: Additional Heater And Parking Heater
Courtesy of VOLVO CARS CORPORATION

If the parking heater has been programmed and the driver comes to the car earlier than anticipated, the additional heater will not engage until the car is started. The additional heater then determines if the heater should be on or off, even if the driver attempts to disengages the heater using the control stalk.

REMOTE START

Fig. 35: Remote Starting
Courtesy of VOLVO CARS CORPORATION

Cars with an accessory electronic module can have a remote start function for the heater. This allows the heater to be started using a pager. A stop or start signal is transmitted from the accessory electronic module (4/78) to the central electronic module which starts the heater (4/7). This function is available for both fuel driven and electrical heaters.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 36: Additional Heater And Parking Heater
Courtesy of VOLVO CARS CORPORATION

The key role of the additional and parking heater (combustion preheater module) is to manage the function for:

- Additional heater
- Parking heater
- Electrical heater
- Residual heater
- Remote start.

The same control module is used for both the additional heater and the parking heater. Depending on the vehicle configuration, the heater can function as an additional heater or as a parking heater. The additional heater is standard in some markets (cold climates). The heater which uses radiant heat from the engine is not capable of maintaining a comfortable passenger compartment temperature.

The control module is positioned in the front left corner of the car in front of the wheel. A large number of the heater functions are controlled by the central electronic module.

The combustion preheater module communicates partly with components which are directly connected and partly with other control modules and components via serial communication.

The combustion preheater module is not a CAN node. It is a slave node of the central electronic module which uses serial communication.

The control module checks activations and input and output signals through an integrated diagnostic system Diagnostic trouble codes (DTCs) are validated in the combustion preheater module if the control module detects an error. In certain cases the control module replaces the faulty signal with a substitute value.

Any diagnostic trouble codes (DTCs) are then sent to the central electronic module where they are stored. The data can be read off using the diagnostic tool.

A simple way to check that the combustion preheater module is supplied with power is to activate the heater. On cars with a parking heater the heater can be activated using the control stalk on the steering wheel. For cars with an additional heater, use the diagnostic tool to activate the heater. The diagnostic tool can be used to start the heater even if diagnostic trouble codes (DTCs) which would prevent the heater from starting are stored.

SIGNALS

The table below summarizes input and output signals to and from the combustion preheater module. The signal types are divided into directly connected signals, serial communication and Control area network (CAN) communication. The illustration below displays the same information with the Volvo part numbers.

Input signals	Output signals
Directly connected: Flame sensor (photo sensor) Coolant temperature sensor (NTC resistor) Fan motor reading (Electromotive force supply)	**Directly connected:** (power supply unless otherwise stated) Fuel pump Water pump Glow plugs (pulse width modulation (PWM)) Combustion fan (pulse width modulation (PWM)) (The supply relay must be active before the components can be activated)
Via serial communication: Start/stop signal for the heater	**Via serial communication:** (The heater communicates with the central electronic module via serial communication) Heater operating status Coolant temperature Diagnostic trouble code (DTC) list Heater running time
Via Control Area Network (CAN): ECM, 4/46 Driver Information Module, 5/1 Steering wheel module, 3/130 Climate control module, 3/112 Rear electrical module, 4/58 Driver's door module/passenger door module, 3/126-127 Accessory Electronic Module, 4/78 SRS, 4/9	**Via CAN communication:** (The heater communicates with the rest of the Control area network (CAN) via the central electronic module) Driver Information Module, 5/1 Steering wheel module, 3/130 Climate control module, 3/112 Accessory Electronic Module, 4/78

ALARM (2003-2004)

SIGNALS

The table below summarizes the input signals to and output signals from the different control modules for the alarm function. The signal types are divided into directly connected signals, serial communication and control area network (CAN) communication.

Directly connected input signals from the sensors / switches to the control module:	Directly connected output signals to the controlled components / functions from the control module:
Central electronic module (CEM) (4/56) • All doors, closed/open • Rear doors, locked/unlocked • Tailgate, closed / open • Hood, closed/open	**Central electronic module (CEM)** (4/56) • The turn signal lamps, on/off • Alarm diode (3/112), on/off. (via the climate control module (CCM).
The climate control module (3/112) • Switch for reduced alarm, on/off.	**The climate control module** (3/112) • Alarm diode, on/off. Direct cable from the central electronic module through the climate control module.
The driver's door module (3/126) • Driver's door, locked/unlocked • Key, locking / neutral position/ unlocking.	
The passenger door module (3/127) • The passenger door, locked/unlocked.	

Received information to control modules via Controller Area Network (CAN):	Transmitted information to control modules via Controller Area Network (CAN):
The central electronic module (4/56) receives from: The climate control module (3/112) • Switch for reduced alarm, on/off. Driver's door module (DDM) (3/126) • Driver's door, locked/unlocked • Key, locking / unlocking. Passenger door module (3/127) • Passenger door, locked/unlocked. Rear electronic module (4/58) • Vehicle inclination sensor status from the inclination sensor module.	**The central electronic module (4/56) transmits to:** The driver information module (5/1) • Text message in the text window.

Upper electronic module (4/70) • Button status from the remote control, LOCK/UNLOCK • Battery status siren • The status of the Mass movement sensor.	
Driver information module (5/1) receives from: The central electronic module (CEM) (4/56) • Text message.	**The upper electronic module (4/70) transmits to:** The central electronic module (CEM) (4/56) • Remote control signal. LOCK, UNLOCK, BOOT • The status of the Mass movement sensor • Battery status siren.

Received information to control modules via serial communication:	Transmitted information to control modules via serial communication:
The rear electronic module (4/58) receives from: Inclination sensor module (7/100) • Vehicle inclination sensor status.	**The upper electronic module (4/70) transmits to:** Siren control module (16/35) • Activate/deactivate the siren • The mass movement sensor (7/122), on/off.
The upper electronic module (4/70) receives from: The mass movement sensor (7/122) • Movement in the passenger compartment. Siren control module (16/35) • Battery status.	**Rear electronic module (4/58) transmits to:** Inclination sensor module (7/100), on/off.

SYSTEM DESCRIPTION

GENERAL INFORMATION

Fig. 38: Alarm Function
Courtesy of VOLVO CARS CORPORATION

The alarm function is a distributed function and uses a number of control modules for its function.

The control modules used for the alarm function are:

- Central electronic module
- Climate control module
- Driver's door module
- Driver information module
- Inclination sensor module
- Mass movement sensor
- Passenger door module
- Rear electronic module
- Siren control module
- Upper electronic module.

TERMINOLOGY

The following terms are used in information about the alarm.

Activated : The car is locked and the alarm protects the car.

Deactivated : The alarm is switched off and no longer protects the car.

Reactivating : The alarm has activated itself and protects the car.

Deployed : The alarm has started and the siren sounds.

CENTRAL ELECTRONIC MODULE

The central electronic module (4/56) is the main control module for alarm functionality. The central electronic module determines how the alarm should be activated, deactivated or deployed by receiving information on the Controller Area Network (CAN) from other control modules and via the directly connected signal cables from the components.

Signal cables are directly connected to the central electronic module from:

- Switch in the lock units in all doors (3/74-77), open/closed
- Switch in the lock units in the rear side doors (3/76-77), locked / unlocked
- Switch hood (3/62), open/closed

The central electronic module is controlled via a direct cable:

- All turn signal lamps.

CLIMATE CONTROL MODULE

The climate control module (3/112) transmits information via the Controller area network (CAN) to the central electronic module about the status of the switch for reduced alarm (3/174).

Signal cables are directly connected to the climate control module from:

- Switch for reduced alarm (3/174), on/off.

The climate control module controls via direct cables:

- Alarm diode (7/12) in the dashboard, on/off. The signal is received via the directly connected cable from the central electronic module.

DRIVER'S DOOR MODULE

The driver's door module, (3/126) transmits information via the Controller area network (CAN) to the central electronic module if the lock is locked or unlocked in the driver's door and if the door has been unlocked using a key.

Signal cables are directly connected to the driver's door module from:

- Switch in the lock units in the driver's doors (3/74), locked / unlocked
- Switch in the lock units in the driver's doors (3/74), locking / neutral position / unlocking. The signal comes from the door lock and indicates the position of the door key in the lock.

DRIVER INFORMATION MODULE

Driver information module (5/1) gives text messages in the text window and receives information from the central electronic module via the Controller area network (CAN). The text messages given are information about the status of the alarm system.

INCLINATION SENSOR MODULE (MARKET DEPENDENT/OPTION)

The Inclination Sensor Module (7/100) transmits information via the serial communication (Volcano Lite) to the rear electronic module, about the vehicle inclination sensor status. The rear electrical module transmits information to the central electronic module via the Controller area network (CAN).

MASS MOVEMENT SENSOR (MARKET DEPENDENT/OPTION)

The mass movement sensor (7/122) transmits information about the movement in the car to the upper electrical module via the serial communication (Volcano Lite). The upper electrical module transmits information to the central electronic module via the Controller area network (CAN).

PASSENGER DOOR MODULE

The passenger door module (3/127) transmits information via the Controller area network (CAN) to the central electronic module if the lock is locked or unlocked in the passenger door.

Signal cables are directly connected to the passenger door module from:

- Switch in the lock unit in the passenger door, locked/unlocked.

REAR ELECTRONIC MODULE

The rear electrical module (4/58) transmits information via the Controller area network (CAN) to the central electronic module about the status of the inclination sensor module. Information about the status is transmitted by the Inclination Sensor Module to the rear electrical module.

SIREN CONTROL MODULE

The task of the control module is to supply the car with the siren sound. The siren control module (16/35) can activate the siren noise in three ways:

- The central electronic module transmits information via the controller area network to the upper electronic module to deploy the alarm. The upper electronic module transmits information via serial communication (Volcano Lite) to the siren control module, which starts the siren
- The siren control module has an integrated battery which is used as a back-up in the event of an alarm.

The battery charges via an integrated charger. The siren control module monitors the power supply from the car battery to the control module. If the voltage from the car battery suddenly drops (open-circuit in the cable) the siren is activated

- The siren control module monitors the communication cable from the upper electronic module (life pulse) and if the communication ceases the siren is activated.

The siren control module transmits information about the status of the internal battery to the UEM via serial communication via serial communication (Volcano Lite).

UPPER ELECTRONIC MODULE

The upper electronic module (4/70) transmits information via the Control area network (CAN) to the central electronic module, about which button on the remote control is depressed and the status of the siren.

The central electronic module in turn sends information to the upper electronic module via the Controller area network (CAN), if the siren must be activated. The upper electronic module transmits information via serial communication (Volcano Lite) to the siren control module, which activates the siren.

SYSTEM OVERVIEW

LOCATION OF COMPONENTS

Fig. 39: Location Of Alarm Components
Courtesy of VOLVO CARS CORPORATION

The alarm function uses the following components (may differ depending on the options and market):

Position	Component	Position	Component
3/62	Switch in hood catch	7/12	Alarm diode
3/74-3/77	Switches in door locks	7/100	Inclination sensor module. Option /accessory
3/78	Switch in trunk lock	7/122	Mass movement sensor. Option /accessory
3/112	Climate control module	7/135-7/137	Resistive wires. Market dependent, option
3/126, 3/127	Drivers door module / Passenger door module	10/13, 10/14	Left and right turn signal lamps, front
3/174	Switch for reduced alarm. Only on cars with mass movement sensors and inclination sensor modules.	10/15, 10/16	Left and right turn signal lamps, Side
4/56	Central electronic module	10/54, 10/47	Left and right turn signal lamps, Rear
4/58	Rear electronic module	16/35	Siren control module
4/70	Upper electronic module		Key and lock cylinder
5/1	Driver information module		Remote control

TERMINOLOGY

The following terms are used in information about the alarm.

Activated : The car is locked and the alarm protects the car.

Deactivated : The alarm is switched off and no longer protects the car.

Reactivating : The alarm has activated itself and protects the car.

Deployed : The alarm has started and the siren sounds.

ALARM SYSTEM

There are different versions of the alarm system. Some of the versions are market dependent or options:

- **Basic Alarm** . Doors, hood and tailgate
- **Extended alarm** . Has one or more of the following as additions to the basic Alarm. Mass movement sensor, the inclination sensor module and glass wire
- **Number of alarm cycles** . Market dependent. There are two choices, 1 or 10 cycles. The alarm cycle is the number of times the alarm sounds when it has been deployed. An alarm cycle means that the siren

sounds for approximately 25 seconds and the hazard warning signal flashers flash for approximately 5 minutes. Once the alarm has been deployed the alarm is reactivated. If a door or hatch is left open, that door or hatch will not be included in the alarm loop when the alarm is activated once again.

Components and switches differ depending on the model year, version and equipment.

ACTIVATING THE ALARM

The alarm can be activated as follows:

- Using the remote control LOCK button
- Using the key in the driver's door lock cylinder (market dependent).

25 seconds after activating the alarm the car is fully protected. An acknowledgment that the alarm is activated is obtained by the alarm diode on the dashboard flashing once per second. The alarm diode does not flash and the car is not alarmed if a door is open or if a fault occurs.

DEACTIVATING THE ALARM

The alarm can be deactivated as follows:

- Using the remote control UNLOCK button
- Using the key in the driver's door lock cylinder (market dependent)
- Using the key in the driver's door lock cylinder and then turning the ignition to position II
- If the key is inserted in the ignition switch within 25 seconds after the alarm is activated. This is a safety feature which prevents the alarm being deployed when a driver presses down the lock button on the remote control by mistake when sitting inside the car. The alarm is deployed if the driver takes longer than 25 seconds from depressing the lock button to inserting the key in the ignition.

An acknowledgment that the alarm is deactivated is obtained by the alarm diode on the dashboard going out and not flashing.

REDUCED ALARM

If the car is equipped with a mass movement sensor and/or an inclination sensor module, these can be deactivated temporarily if required.

The inclination sensor and mass movement modules are deactivated using the switch for reduced alarm on the climate control module.

The ignition key should be in position I, 0 or removed (time factor applies for a removed key).

Once the switch has been pressed an LED lights up in the switch at the same time as a (reduced alarm) message is displayed in the driver information module.

Next time the ignition key is inserted and turned to position II, the system is reset. This means that the next time the vehicle is locked from the outside, using the key or the remote control, the inclination sensor and the mass

movement sensor will be activated. A message (fully alarmed) is displayed in the driver information module.

SPECIAL FUNCTIONS

- The alarm is also activated when automatic relocking occurs
- The alarm is activated automatically with a certain amount of delay if all doors, the tailgate and hood are closed, when the key is in position 0 or I. This function is market dependent
- If any door is not closed the alarm will not be completely activated. If a closed door is opened the alarm is deployed, the open door(s) are disconnected from the alarm loop. The mass movement sensor and the inclination sensor module are activated after a delay. If the open door or doors is/are closed, the alarm will once again be completely activated.

ACKNOWLEDGMENTS

When the alarm is activated it is acknowledged by the alarm diode on the dashboard flashing once per second.

When the alarm is deactivated it is acknowledged by the alarm diode stopping flashing.

In the event of the alarm being deployed the following warnings are displayed to the driver:

- When the car is unlocked the alarm diode flashes approximately 3 times per second
- When the ignition key is turned to position I, a message is displayed (alarm deployed, check the car) in the driver information module.

ALARM

The alarm signals in different ways depending on what has caused the alarm to deploy:

- When the alarm has deployed by the doors, tailgate, hood, glass wires, angle or movement in the sensor, the alarm will start an alarm cycle. An alarm cycle means that the siren sounds for approximately 25 seconds and the hazard warning signal flashers flash for approximately 5 minutes. If the car has more alarm cycles (market dependent) the alarm will deploy again within 5 seconds, if the cause is still present. This procedure is repeated for the number of alarm cycles the car is programmed for. When all the alarm cycles have been run through the alarm is activated again. If a door or hatch is left open that door or hatch will not be included in the alarm loop when the alarm is activated once again
- If the battery voltage for the car suddenly disappears the siren sounds for approximately 5 minutes, then stops. In this instance the siren is supplied with power from its internal battery and does not sound as loud as when the siren is supplied with power by the car battery.

ALARM (2005-2012)

DESIGN

REAR ELECTRONIC MODULE (REM)

Fig. 40: Locating Rear Electronic Module (REM)
Courtesy of VOLVO CARS CORPORATION

The rear electronic module (REM) is the main unit for alarm functions.

The control module communicates with units that are connected directly or serially and via CAN communication. The control module has a number of sensors connected to it and carries out the appropriate actions depending on the status of the sensors and input signals from other control modules.

SWITCHES IN THE LOCK UNITS

Fig. 41: Identifying Switches In Lock Units

Courtesy of VOLVO CARS CORPORATION

A switch is fitted in each lock unit for the doors and trunk lid/tailgate. Vehicles equipped with an alarm have a switch in the hood lock. The switches are closed when the respective door or hatch is closed. There is no switch for the fuel tank filler cover.

At regular intervals, the rear electronic module (REM) checks if the switches are closed when the alarm is activated. If the rear electronic module (REM) detects that a switch opens, the alarm is triggered.

If the rear electronic module (REM) detects a switch that is not closed when central locking is engaged and alarm activation is to be carried out, the inclination sensor module and the mass movement sensor module (MMS), or movement sensor (IMS), will not be activated. Similarly, signals from a switch that was not closed during activation will be disregarded. No flash is given in acknowledgment before all switches are closed.

SIREN (SCM/BBS)

Fig. 42: Locating Siren
Courtesy of VOLVO CARS CORPORATION

The siren is used as a sound source for the alarm function. The siren is located in a protected position under the fender liner in the front right wheel housing. From and incl. structure week 201128 the siren is available in two versions, with or without internal vehicle inclination sensor. The type of siren installed in the vehicle depends on the market and the customer's wishes.

The siren sounds if the power supply to it is cut or if communication with the master electronic module (UEM/REM) fails while the alarm is activated. The siren contains an internal battery which is charged when the ignition is on or the engine is running. The battery service life is limited and depends on the local climate. The battery cannot be replaced by itself. Any alarm cause can be read from VADIS. This states what caused the alarm.

The siren is powered via a fuse from the central electronic module (CEM) The siren is grounded in the engine compartment.

There are diagnostics for the siren.

From and incl. structure week 201128 the siren on XC90 is connected to and communicates with REM instead

of UEM.

MASS MOVEMENT SENSOR MODULE (MMS)

Fig. 43: Locating Mass Movement Sensor Module (MMS)
Courtesy of VOLVO CARS CORPORATION

NOTE: For XC90 MY 2012- the Mass movement sensor module (MMS) is replaced with ultrasonic sensor module (IMS).

The mass movement sensor module (MMS) is located in the roof under its own panels.

The two sensors in the XC90 are located along the front edge of the roof and in the roof above the cargo compartment.

The mass movement sensor module (MMS) is used to detect movement in the passenger compartment when the alarm is activated.

When the alarm is activated, the upper electronic module (UEM) carries out a check of the sensors.

The sensors communicate serially with the upper electronic module (UEM). If two sensors are installed, these are connected in parallel to the upper electronic module (UEM).

When the sensors are activated, they transmit microwaves into the vehicle. The microwaves bounce back from the interior of the vehicle and the sensors react to variations in the rebounding waves. A system that uses microwaves is more stable than a system that uses ultrasound sensors and reduces the number of false alarms. For example, microwaves are not affected by the changing temperature of different layers of air inside a vehicle parked in the sun. The cause of the alarm can be read off and verified via VIDA (Volvo scan tool).

The mass movement sensor module (MMS) is powered and grounded via the upper electronic module (UEM).

ULTRASONIC SENSOR MODULE (IMS) (ONLY XC90 MY 2012-)

Fig. 44: Identifying Ultrasonic Sensor Module (IMS)
Courtesy of VOLVO CARS CORPORATION

The ultrasonic sensor module (IMS) is located in a cover in the ceiling. The ultrasonic sensor module (IMS) is used to detect movements inside the passenger compartment when the alarm has been activated. The aim is to detect anyone trying to reach in and steal a bag or similar or example. When the sensor is activated, an internal self test is performed and informs the Central electronic module (CEM) of the result. If the test failed the Central electronic module (CEM) stores a DTC. The sensors communicate serially and are powered via the Upper electronic module (UEM). When the sensor is activated it transmits ultrasound inside the passenger compartment. The sound waves reflect back to the sensor and if the sensor detects a change in reflections or movements in the passenger compartment, the alarm is tripped.

NOTE: The sensor's performance is affected by air turbulence and therefore all windows and any roof hatches must be closed for the sensor to work optimally.

INCLINATION SENSOR MODULE (ISM) (STRUCTURE WEEK -201127)

Fig. 45: Locating Inclination Sensor Module (ISM)
Courtesy of VOLVO CARS CORPORATION

The inclination sensor module (ISM) is fitted near the rear electronic module (REM) and gives input signals to the rear electronic module (REM) when the alarm is activated. The sensor registers changes in the vehicle angle that would occur during an attempted tow or theft of a wheel, for example. The inclination sensor module (ISM)

is connected in series with and powered by the rear electronic module (REM). The inclination sensor module (ISM) is grounded to the body. The cause of the alarm can be read off and verified via VIDA (Volvo scan tool).

INCLINATION SENSOR MODULE ALARM (BBS-IS) (XC90 STRUCTURE WEEK 201128-)

Fig. 46: Locating Siren
Courtesy of VOLVO CARS CORPORATION

If the vehicle is equipped with a vehicle inclination sensor, the sensor is integrated in the siren. The vehicle inclination sensor reacts to changes in the angle of lean of the vehicle and transmits a signal to the Rear electronic module (REM). While the vehicle inclination sensor is mounted in the siren it is counted as a separate unit. If the vehicle inclination sensor indicates that the vehicle is being lifted the Rear electronic module (REM) must send an activation signal to the siren. In this case the siren cannot trigger an alarm by itself.

The siren is powered via a fuse from the central electronic module (CEM) The siren is grounded in the engine compartment.

ALARM LED

Fig. 47: Sun Sensor
Courtesy of VOLVO CARS CORPORATION

The alarm LED is located on top of the dashboard in the same shell as the sun sensor and twilight sensor. The LED is directly connected to the rear electronic module (REM) and is used for indicating alarm status.

When the alarm is activated, the LED will flash approximately once every two seconds.

If the alarm is triggered, the LED will begin to flash rapidly (approximately 5 times per second) and continue to flash as long as the alarm continues. Once the alarm cycle is concluded, the LED will once again begin to flash slowly.

If the alarm has been triggered, the LED will begin to flash rapidly again (approximately 5 times per second) after the vehicle is unlocked until the ignition is switched on. This is an indication to the driver that the alarm has been triggered.

SWITCH FOR REDUCED ALARM

Fig. 48: Locating Switch For Reduced Alarm
Courtesy of VOLVO CARS CORPORATION

NOTE: The switches can be positioned in a different order than indicated in the illustration depending on vehicle configuration and equipment.

The switch for reduced alarm is located on the climate control comfort panel. The switch is used to temporarily deactivate the inclination sensor module and mass movement sensor module (MMS) alternatively ultrasonic sensor module (IMS) functions. When the function is activated, deadlock mode will not engage after the vehicle is locked. The function can only be activated when the ignition is in position I, 0 or after the ignition has been switched off and up to one minute after the ignition key has been removed from the ignition switch.

The switch has an integrated LED that indicates if the function is activated and messages will be displayed in the driver information module (DIM). However, messages are not displayed once the key is removed.

With the switch the alarm can be set to so called garage mode if the car is configured for passive activation (option for certain markets). This mode is activated if the switch is pressed in and the unlock button on the remote control is pressed in within 5 seconds. In garage mode there will be no passive activation of the alarm. This mode is active for 24 hours after activation or until any button is pressed on the remote control.

DIAGNOSTIC FUNCTIONS

GENERAL INFORMATION

The rear electronic module (REM) is the main unit for the alarm function and contains diagnostics for the alarm function.

READING OFF THE ALARM CAUSE

The three latest alarm causes can be read off with this function.

Alarm cause:

- Right front door
- Left front door
- Right rear door
- Left rear door
- Hood
- Luggage Compartment Lid
- Ignition (non-permitted start attempt)
- Inclination Sensor Module alarm
- Voltage drop siren
- Rear mass movement sensor module, Rear sensor for the XC90.
- Front mass movement sensor module. Front sensor for the XC90.

FUNCTION

ACTIVATION

Fig. 49: Identifying Volvo Component Designations
Courtesy of VOLVO CARS CORPORATION

XC90 from and incl. structure week 201128-

Fig. 50: Identifying Volvo Component Designations
Courtesy of VOLVO CARS CORPORATION

With the remote control

When the upper electronic module (UEM) receives a locking command, it sends a command to the rear electronic module (REM). The rear electronic module (REM) first engages central locking and then activates the alarm. The alarm LED will begin to flash directly after system activation. However, the rear electronic module (REM) will disregard signals from the mass movement sensor module (MMS), or ultrasonic sensor module (IMS) or the inclination sensor module (ISM) until 25 seconds have transpired or after deadlock mode has been engaged by the central locking function.

With the key

An alarm activation function for a vehicle that is locked with the key is available in certain markets. In this case, a locking command is sent to the rear electronic module (REM) from the driver door module (DDM) when a switch in the driver's door lock cylinder is actuated. When the rear electronic module (REM) has engaged the central lock, the alarm is activated. This function is controlled by the vehicle configuration file which is stored in the central electronic module (CEM).

With the interior central locking switches

The alarm can be activated after an interior central locking switch has been used to engage the central locking in vehicles that are configured for a dual stage central locking function. The vehicle will be fully protected

approximately 25 seconds after the last door is closed.

Passive activation

There is a passive alarm activation function available on the Belgian and Israeli markets. After a driving cycle has been completed (ignition on, engine running, ignition off), the driver's door has been opened and closed and the ignition key is in position 0, 1 or removed, the alarm will be activated after approximately 1.5 minutes. Depressing the reduced alarm switch and depressing the remote control unlocking button within 5 seconds deactivates the function (garage mode). The function is deactivated for 24 hours or until a button is pushed on the remote control.

TRIGGERING THE ALARM

If the alarm is in active mode and the rear electronic module (REM) receives an indication from a directly connected sensor or the upper electronic module (UEM), a so-called alarm cycle will be initiated. The rear electronic module (REM) or Upper Electronic Module (UEM) sends a command to the siren for it to activate. At the same time, the rear electronic module (REM) sends a direction indicator lamp activation command to the central electronic module (CEM). The siren sounds for a period of approximately 25 seconds and then stops. The light signal will continue for an additional 4.5 minutes. The function for alarm redeployment (if for example, a door is still open) is market dependent.

DEACTIVATION

In order to deactivate the alarm, the vehicle can be unlocked with the remote control. The rear electronic module (REM) receives a request for alarm deactivation from the upper electronic module (UEM) if the upper electronic module (UEM) receives an unlocking command from the remote control.

NOTE: This means that if a locked vehicle with an activated alarm is then unlocked with the ignition key instead of the remote control, the alarm will be triggered. Exceptions include a vehicle with an activated function for alarm activation and deactivation with the key.

The alarm function can also be deactivated locally if the trunk lid/tailgate unlocking button on the remote control is depressed. In this case, the rear electronic module (REM) disregards signals from the switch indicating an open trunk lid/tailgate in the trunk lid/tailgate lock unit. The level sensor and mass movement sensor module (MMS) or ultrasonic sensor module (IMS) will also be deactivated temporarily. The vehicle alarm is reactivated once the hatch is closed.

The alarm can also be deactivated if an approved key is inserted in the ignition switch and is turned to position II.

RESETTING THE ALARM

If the alarm has been triggered, it can be reset in two ways; by depressing the unlocking button on the remote control or by turning the ignition key to position II.

REDUCED ALARM FUNCTION

The switch for reduced alarm function is located in the climate control comfort panel. The switch is used to temporarily deactivate the level sensor, mass movement sensor module (MMS) or ultrasonic sensor module (IMS) and deadlock mode when the vehicle is locked. An integrated LED in the switch indicates when the function is activated.

The function is activated during a locking cycle, i. e. from the time the button is depressed and the vehicle is locked until the vehicle is unlocked. When the ignition is once again turned to position II, reduced function is deactivated.

Examples of applications for this function include when a person or pet remains inside the vehicle after the vehicle has been locked, and if the vehicle is transported by tow truck or onboard a ferry.

SYSTEM OVERVIEW

GENERAL INFORMATION

Fig. 51: Identifying Volvo Component Designations
Courtesy of VOLVO CARS CORPORATION

The alarm is an entry protection system for the vehicle. The aim is to prevent anyone getting into the vehicle or manipulating the vehicle in any way without being detected.

The alarm is available in various configurations:

- **Basic configuration.** This configuration includes switches in the lock units (including switches in the hood and trunk lid/tailgate), an alarm LED and a siren (SCM).
  - Mass movement sensor module (MMS) or ultrasonic sensor module (IMS) (IMS replaces MMS for XC90 MY 2012-)
  - Inclination Sensor Module (ISM) (BBS-IS replaces ISM from and incl. structure week 201128)
- **Extended configuration.** Can include one or more of the following components:
  - Mass movement sensor module (MMS) or ultrasonic sensor module (IMS) (IMS replaces MMS for XC90 MY 2012-)
  - Inclination Sensor Module (ISM) (BBS-IS replaces ISM from and incl. structure week 201128)

Definitions:

- **Deactivated:** the alarm is not activated and is not protecting the vehicle
- **Activated:** the alarm is protecting the vehicle and will be triggered if there is an input signal from one of the sensors
- **Deployed:** An alarm cycle is initiated. The siren sounds for 25 seconds and the direction indicators flash for approx. 5 minutes. When the alarm cycle is finished, the alarm goes to activated mode.

SIGNALS

The tables below summarize the input and output signals to the units in the system for the alarm. The signal types are divided into directly connected signals, serial communication and controller area network (CAN) communication.

REAR ELECTRONIC MODULE (REM) (4/58):

Input signals	Output signals
Directly connected: • Switch in lock unit (3/74) for indicating open driver's door. • Switch in lock unit (3/75) for indicating open passenger door. • Switch in lock unit (3/76) for indicating open door, left rear. • Switch in lock unit (3/77) for indicating open door, right rear. • Switch in hood lock (3/62) for indicating open hood. • Switch in lock unit (3/78) for indicating open trunk lid/tailgate.	**Directly connected:** • Alarm LED (7/12) for indicating alarm status. • Inclination Sensor Module alarm (ISM) (7/100), voltage feed (applies to and incl. structure week 201127).
Via serial communication: • Inclination Sensor Module alarm (7/100), for information on vehicle's position, or integrated Inclination Sensor in siren (BBS-	**Via serial communication:** • Inclination Sensor Module alarm (7/100), for status request, or integrated Inclination Sensor in siren (BBS-IS) (from and incl. structure

IS) (from and incl. structure week 201128). • Communication with siren (SCM) (16/35) (from and incl. structure week 201128).	week 201128). • Communication with siren (SCM) (16/35) (from and incl. structure week 201128).
Via CAN communication (LS-CAN): • Reduced alarm switch (3/174) via the climate control module (CCM) (3/112) for deactivation of the inclination sensor module (ISM), the mass movement sensor module (MMS), or ultrasonic sensor module (IMS) (7/199) and deadlock mode. • Upper electronic module (UEM) (4/70) for signals from the mass movement sensor module (MMS) or ultrasonic sensor module (IMS) (7/199), siren (SCM) and commands from the remote control.	**Via CAN communication (LS-CAN):** • The driver information module (DIM) (5/1) for information about which message is to be displayed. • Upper electronic module (UEM) (4/70) for siren (SCM) activation. • Central electronic module (CEM) (4/56) for activating direction indicator lamps when the alarm is triggered and the horn during triggered panic function.

UPPER ELECTRONIC MODULE (UEM) (4/70):

Input signals	Output signals
Directly connected:	**Directly connected:** • **For XC90:(MY-2011)** Mass movement sensor module (MMS) (7/158), rear sensor and mass movement sensor module (MMS) (7/122), front sensor, power supply. The sensors are connected in parallel. • **For XC90 (MY 2012-):** ultrasonic sensor module (IMS) (7/199).
Via serial communication: • **For XC90:(MY-2011)** Mass movement sensor module (MMS) (7/158), rear sensor and mass movement sensor module (MMS) (7/122), front sensor. The sensors are connected in parallel. • **For XC90 (MY 2012-):** ultrasonic sensor module (IMS) (7/199). • Communication with siren (SCM) (16/35) (applies to and incl. structure week 201127).	**Via serial communication:** • **For XC90:(MY-2011)** Mass movement sensor module (MMS) (7/158), rear sensor and mass movement sensor module (MMS) (7/122), front sensor. The sensors are connected in parallel. • **For XC90 (MY 2012-):** ultrasonic sensor module (IMS) (7/199). • Communication with siren (SCM) (16/35) (applies to and incl. structure week 201127).
Via CAN communication (LS-CAN): • Rear electronic module (REM) (4/58) with request for function activation.	**Via CAN communication (LS-CAN):** • Rear electronic module (REM) (4/58) with command for siren (SCM) activation.

ANTENNA MODULE (ATM) (2003-2006)

DESIGN

AM/FM

The antenna module (ATM) consists of a thin film antenna and an AM/FM receiver. The control module can be upgraded with GPS and traffic message channel (TMC) units.

Information from the AM/FM receiver consists of radio signals received on the AM or FM-waveband.

The signal from the AM/FM tuner is transmitted to the audio control module (AUD) and infotainment module (ICM) via the MOST network.

If the antenna module (ATM) is not supplied with voltage communication on the MOST net does not function and the Infotainment system shuts down.

GPS

The data transmitted from the GPS unit consists of signals received from GPS satellites.

The GPS unit transmits the signal to the multimedia module (MMM) via the MOST network.

The navigation system requires at least three satellites in order calculate the position of the car. The position calculated from the GPS satellites is accurate to within 25 meters.

The power supply to the GPS unit is from the antenna module (ATM).

The GPS unit is integrated with the antenna module (ATM) and transmits signals via the MOST network.

NOTE: If the GPS signal is being diagnosed because it is missing, the signal should be tested outdoors. This is because the signal may be blocked if the vehicle is indoors.

TRAFFIC MESSAGE CHANNEL (TMC)

The traffic message channel (TMC) signal is captured by the TMC receiver and transmitted to the receiver in the multimedia module (MMM) via the MOST network.

The information is then displayed on the screen.

The traffic message channel (TMC) receiver is integrated with the antenna module (ATM) and transmits signals via the MOST network.

This also applies to FM Multiplex, which is the Japanese equivalent of traffic message channel (TMC).

DIAGNOSTIC FUNCTIONS

GENERAL INFORMATION

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal

functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. A fault which is detected in the most recent operating cycle is defined as permanent. Other faults are defined as intermittent.

The control module can store up to seven diagnostic trouble codes (DTCs).

Should a fault disappear for any reason after being permanently stored in the control module as a diagnostic trouble code (DTC), the information remains stored in the control module.

If a fault is no longer permanent, the diagnostic trouble code (DTC) remains as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

NOTE: Certain functions are unavailable until the diagnostic trouble codes (DTCs) have been erased.

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N.

READING OFF EXTENDED FAULT-TRACING INFORMATION

This function can be used to read parameters, status identifiers and counters stored at the same time as a diagnostic trouble code (DTC). These are called frozen values.

For further information, see **DESCRIPTION OF VEHICLE COMMUNICATION INFORMATION** .

READING OFF THE PARAMETERS

Using this function, the status or value of parameters can be read off. The presentation of the status or value can be obtained graphically or digitally. For further information about the different parameters, see **DESCRIPTION OF PARAMETERS** .

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the antenna module (ATM) When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

The control module is located in the rear section of the roof. Detach the headlining in the passenger compartment if the control module is replaced.

After replacing the control module, the unique serial numbers of the control module are checked by the infotainment control module (ICM). The installed control module will not work if the serial number is incorrect.

Try turning the ignition off and on if there are problems after the software is downloaded and the control module is not working.

The MOST network is used for a total software reload.

FUNCTION

AM/FM RECEPTION

Fig. 52: Identifying Volvo Component Designations
Courtesy of VOLVO CARS CORPORATION

The base unit of the antenna module (ATM) (16/110) has the task of receiving and converting AM and FM signals. The antenna signals are converted to sound signals which are transmitted digitally to the audio control

module (AUD) (16/105) via the MOST network.

The antenna module (ATM) (16/110) receives information from the infotainment module (ICM) (16/1) about which frequency / radio station and which waveband the listener wishes to listen to.

The antenna module (ATM) does not transmit sound signals to the audio module (AUD) if the radio station signal is not strong enough. The antenna module (ATM) is in "MUTE" mode when searching frequencies.

The antenna module (ATM) stores the most recently used frequency for a waveband. When changing from one frequency to another the control module will use the stored frequency.

GPS RECEPTION

The GPS unit (option) has the task of receiving satellite signals for determining position. The antenna module (ATM) (16/110) transmits two different position signals on MOST:

- a received signal from the GPS satellites. Used by the multimedia module (MMM) (16/108) and the phone module (PHM) (16/60)
- a calculated signal. Used by the Phone Module (PHM) (16/60).

The calculated signal is obtained by dead reckoning. The antenna module (ATM) calculates the present position of the car based on the most recent GPS-signal. The control module receives information about direction and speed from the brake control module (BCM) and central electronic module (CEM) via the infotainment module (ICM) (16/1) to calculate the present position.

TRAFFIC MESSAGE CHANNEL (TMC) RECEPTION

The traffic message channel (TMC) receiver in the antenna module (ATM) is an option and has the task of receiving traffic information sent by radio. The antenna module (ATM) transmits information to the multimedia module (MMM).

Traffic message channel (TMC) is a European standardized code system for traffic messages, such as information about road works. The Japanese equivalent is called FM multiplex.

There is no traffic information system in the USA.

SYSTEM OVERVIEW

ANTENNA MODULE (ATM)

Fig. 53: Identifying Antenna Module (ATM)
Courtesy of VOLVO CARS CORPORATION

The main function of the antenna module (ATM) is to handle the antenna signals for:

- AM/FM
- GPS (Global Positioning System), receiving position signals
- Traffic message channel (TMC), receiving traffic information.

The antenna module (ATM) consists of a thin film antenna and a receiver. There is a base unit which only has AM/FM reception. The control module can be upgraded with GPS and traffic message channel (TMC) units. The following types are available:

- base unit with only AM/FM-reception without the possibility of upgrading, for market codes EU and US
- base unit with only AM/FM-reception with the possibility of upgrading, for market codes EU and US
- base unit with only AM/FM-reception with the possibility of upgrading, for market code JP.

The control module is positioned in the rear of the roof. Detach the headlining in the passenger compartment if the control module is replaced.

The antenna module (ATM) uses serial communication on the MOST network to communicate with other control modules.

The control module checks activations and input and output signals via an integrated diagnostic system. A diagnostic trouble code (DTC) is stored if the control module detects a fault.

Any diagnostic trouble codes (DTCs) are stored in the control module memory. This information can be read off using VIDA via the data link connector (DLC) in the car.

If the antenna module (ATM) is not supplied with voltage communication on the MOST net does not function and the Infotainment system shuts down.

SIGNALS

The table below summarizes the input signals to and output signals from the antenna module (ATM). The signal types are divided into directly connected signals and MOST communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected:	**Directly connected:** (power supply unless otherwise stated)
Via MOST communication: • Infotainment Control Module (ICM) (16/1) • Multimedia module (MMM) (16/108).	**Via MOST communication:** • Audio module (AUD) (16/105) • Multimedia module (MMM) (16/108) • Infotainment Control Module (ICM) (16/1) • Phone module (PHM) (16/60).

Fig. 54: Identifying Volvo Component Designations
Courtesy of VOLVO CARS CORPORATION

AUDIO MODULE (AUD) (2003-2006)

DESIGN

CONTROL MODULE

Fig. 55: Identifying Audio Module (Aud)
Courtesy of VOLVO CARS CORPORATION

The audio module (AUD) is an amplifier which is connected to the MOST network. It has the following functions:

- to carry the sound signal transmitted on the MOST network out to the directly connected loudspeakers and to the headsets as analogue signals
- to carry voice messages from the microphone, which is directly connected to the audio module (AUD), to the MOST network
- to transmit requests from the headset panel, which is directly connected to the audio module (AUD), to the relevant control modules on the MOST network to change to the next or the previous track or to change the sound source.

If a subwoofer module (SUB) is installed on the MOST network, the audio module (AUD) can process the incoming signal and transmit it to the subwoofer module (SUB).

There are three versions of the audio module (AUD):

Performance

- Has an output of 25 W per channel. The control module has 4 channels, giving a total output of 100 W.

High Performance

- Has an output of 40 W per channel. The control module has 4 channels, giving a total output of 160 W. There are two versions, one with four headset sockets and one without any headset sockets. These sockets can run headsets with a minimum impedance of 8 ohms.

Premium Sound

- Has an output of 70 W per channel plus an output of 25 W for the channel for the centrally-mounted loudspeaker. The control module has four channels plus the channel for the centrally-mounted loudspeaker. This gives a total output of 305 W. The Premium Sound Audio Module (AUD) has four headset sockets. These sockets can run headsets with a minimum impedance of 8 ohms.

Each version of the audio module (AUD) has a different number of loudspeakers and different loudspeaker models.

All versions of the audio module (AUD) have a microphone input. This is used by the phone module (PHM) for phone calls (handsfree) for example.

FUNCTIONS IN THE AUDIO MODULE (AUD)

The audio module (AUD) can run a number of different functions, but these functions can also be activated by other nodes. An example of these functions is lowering and increasing the volume. The signal comes from the infotainment control module (ICM), but it is the audio module (AUD) that actually changes the volume. The functions are described below.

Functions in the audio module (AUD):

1. **Adjustable volume** , raises and lowers the volume
2. **Adjustable bass** , raises and lowers the bass level
3. **Adjustable treble** , raises and lowers the treble level
4. **System generated sound signals** , assists other nodes in the system with single sound signals generated in the control module, for example alarm signals for the reverse (reverse) warning function
5. **Limiter** , the limiter function in the control module does not permit an increase in the power output level if this leads to a fall in sound quality
6. **Mixing** , mixing allows numerous different sound types to be mixed. In this case, the different sound types are foreground noise, background noise and system generated sound signals. An example of this is where a CD is playing (background noise) and the carphone rings (foreground noise). The ringing signal will be heard through the loudspeakers while the volume of the music drops at the same time
7. **Digital bass speaker output** , the control module transmits sound signals to the bass speakers via the MOST network. The signal is processed in the audio module (AUD) before it is transmitted on the MOST network to the subwoofer module (SUB)
8. **Bass compensation** , the bass from the control module is compensated or modified depending on the volume level and the speed of the car. If the vehicle speed and volume level changes, the bass compensation is also changed
9. **Treble compensation** , the treble in the control module is compensated or modified depending on how the volume is changed. If the volume changes, the treble compensation also changes
10. **Equalizer setting, sound compensation** , there are different settings for the sound from the audio module (AUD). This compensates for factors such as the location of the loudspeakers and the layout of the car interior
11. **Dolby ProLogic II** , a surround decoder for sound reproduction.

There are two types of sound, foreground sound and background sound. The sounds which are foreground and background are listed below.

Foreground sound

- telephone calls

- carphone settings (setting the ring signal)
- navigation
- system generated sound from the audio module (AUD) (different types of alarm sound)
- traffic messages.

Background sound

- analogue radio, AM/FM
- digital radio, DAB
- CD player
- MD player.

The functions in the different versions of the audio module (AUD) are:

Performance

1. adjustable volume
2. adjustable bass level
3. adjustable treble level
4. system generated sound signals
5. limiter.

High Performance

1. adjustable volume
2. adjustable bass level
3. adjustable treble level
4. system generated sound signals
5. limiter
6. mixing
7. digital bass speaker output
8. bass compensation
9. treble compensation
10. equalizer.

Premium Sound

1. adjustable volume
2. adjustable bass level
3. adjustable treble level
4. system generated sound signals

5. limiter
6. mixing
7. digital bass speaker output
8. bass compensation
9. treble compensation
10. equalizer
11. DPL2 - Dolby ProLogic II.

LOUDSPEAKERS

Fig. 56: Identifying Loudspeakers
Courtesy of VOLVO CARS CORPORATION

Two pairs of loudspeakers and one center loudspeaker can be installed in the car.

The two pairs of loudspeakers are:

- front loudspeakers in the front doors
- rear loudspeakers in the rear doors.

The center loudspeaker is positioned in the middle of the dashboard.

In some versions of the audio module (AUD), a treble speaker can be connected to the front and rear speakers. The treble speakers for the front loudspeakers are positioned in the front door at the same height as the door mirrors. For the rear loudspeakers, the treble speakers are positioned in the D-post.

The three audio module (AUD) versions have different loudspeaker arrangements:

Performance

- one pair of front bass speakers
- one pair of rear loudspeakers.

Each loudspeaker consists of a transducer for the entire frequency range. There are no treble speakers connected to this version.

High Performance

- a pair of front bass / mid-range loudspeakers with treble speakers
- a rear pair of loudspeakers (coaxial*) with treble speakers.

The front treble speakers are electrically connected to the same signal cable as the front loudspeakers. The rear treble speakers are electrically connected to the rear loudspeakers.

Premium Sound

- a front pair of 3-way loudspeakers (consisting of a pair of 2-way loudspeakers with treble speakers)
- a rear pair of loudspeakers (coaxial*) with treble speakers.
- a centrally-mounted loudspeaker in the dashboard.

The front treble speakers are electrically connected to the same signal cable as the front loudspeakers. The rear treble speakers are electrically connected to the rear loudspeakers.

*Consists of one bass and one treble transducer integrated in the same unit.

TABLE OF LOUDSPEAKER ARRANGEMENTS

System	Front door / door mirror	Front door	Rear door	D-post	Dashboard
Performance	-	165 mm broadband loudspeaker (16/4, 16/3). Impedance 4 ohms.	165 mm broadband loudspeaker (16/6, 16/5). Impedance 4 ohms.	-	-
High Performance	36 mm treble loudspeaker (16/55, 16/56). Impedance 8 ohms.	165 mm bass and midrange loudspeaker (16/4, 16/3). Impedance 2 ohms.	165 mm coaxial loudspeaker (16/6, 16/5). Impedance 2 ohms.	36 mm treble loudspeaker (16/58, 16/57). Impedance 8 ohms.	-
Premium Sound	36 mm treble loudspeaker (16/55, 16/56). Impedance 8 ohms.	165 mm bass loudspeaker, 80 mm midrange loudspeaker (16/4, 16/3). Impedance 4 ohms.	165 mm coaxial loudspeaker (16/6, 16/5). Impedance 6 ohms.	36 mm treble loudspeaker (16/58, 16/57). Impedance 8 ohms.	2 way center loudspeaker (16/26). The impedance is 6 ohms if a display screen is installed for the multimedia module

					(MMM). The impedance is 8 ohms if a display screen is not installed.

HEADSET PANEL

Fig. 57: Locating Headset Panels
Courtesy of VOLVO CARS CORPORATION

Depending on the version of the audio module (AUD), two headset panels can be installed. The panels have two headset sockets each giving a total of four headset sockets.

Each headset socket has a SEL. button which is used to select the sound source, such as CD player, MD player and radio.

Each headset output also has buttons to select the previous and next track or one of the pre-programmed radio channels. The buttons are internally connected to a resistor stage. When the buttons are pressed, different voltages levels are produced. These voltages are interpreted by the control module as three different selections. When any of the buttons are pressed, this data is transmitted to the audio module (AUD). The module then transmits the data via MOST network to the infotainment module (ICM). The infotainment control module (ICM) then changes the track or sound source.

Each headset socket has a volume control which can be used to change the sound level in the headset. The headset panels are in the left and right-hand C-posts.

If a sound source, which has already been selected via the infotainment control module (ICM), is selected the track or radio channel for this sound source cannot be changed via the headset output. There is no difference in priority between the headset outputs. This means that the radio channel or track can be changed via the headset output for a sound source which is being used by another headset output. All headset outputs with the same sound source then change radio channel or track.

The signals to the headset sockets and the buttons on the headset panel are directly connected to the audio module (AUD).

MICROPHONE

Fig. 58: Locating Microphone
Courtesy of VOLVO CARS CORPORATION

All versions of the audio module (AUD) have a microphone which is directly connected to the control module. The microphone is installed in the rear view mirror.

The microphone is used for functions such as handsfree in the phone module (PHM).

DIAGNOSTIC FUNCTIONS

GENERAL INFORMATION

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. A fault which is detected in the most recent operating cycle is defined as permanent. Other faults are defined as intermittent.

Should a fault disappear for any reason after being permanently stored in the control module as a diagnostic trouble code (DTC), the information remains stored in the control module.

If a fault is no longer permanent, the diagnostic trouble code (DTC) remains as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

NOTE: Certain functions are unavailable until the diagnostic trouble codes (DTCs) have

been erased.

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N.

READING OFF EXTENDED FAULT-TRACING INFORMATION

This function can be used to read parameters, status identifiers and counters stored at the same time as a diagnostic trouble code (DTC). These are called frozen values.

For further information, see **DESCRIPTION OF VEHICLE COMMUNICATION INFORMATION** .

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the audio module (AUD). When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

The control module is under the right-hand front seat. The seat must be removed to replace the control module

After replacing the control module, the unique serial numbers of the control module are checked by the infotainment control module (ICM). The installed control module will not work if the serial number is incorrect.

Try turning the ignition off and on if there are problems after the software is downloaded and the control module is not working.

The MOST network is used for a total software reload.

FUNCTION

PLAYING BACK SOUND

Fig. 59: Identifying Volvo Component Designations
Courtesy of VOLVO CARS CORPORATION

All functions in the audio module (AUD) (16/105) are controlled by the signals from other nodes in the MOST network.

To play back sound, a control module transmits a request to the infotainment module (ICM) (16/1). The infotainment control module (ICM) distributes the request to the audio module (AUD). The control module is then able to transmit signals via the MOST network to the audio module (AUD).

The infotainment control module (ICM) (16/1) processes changes to the sound, balance, bass, treble and equalizer settings. It transmits the changes via the MOST network to the audio module (AUD) (16/105) which then carries out the changes.

The control modules on the MOST network which use the audio module (AUD) to play back sound are:

- the antenna module (ATM) (16/110) for AM/FM radio
- the antenna module (ATM) (16/110) for digital radio, DAB
- the phone module (PHM) (16/60) for handsfree calls
- multimedia module (MMM) (16/108) for voice guiding (navigation)
- the MD module (MP1) (16/107) for minidiscs
- the CD module (MP2) (16/106) for compact discs.

The audio module (AUD) can generate simple sound signals which are used for example to warn the driver and passengers if there are problems. These signals are transmitted from the infotainment control module (ICM) to the audio module (AUD).

When the audio module (AUD) has received optical signals on the MOST network, these signals are sent onwards as analog signals to the directly connected front (16/4, 16/3) and rear (16/6, 16/5) loudspeakers. Certain versions of the control module have several directly connected components such as front treble speakers (16/55, 16/56), D-post loudspeakers (16/58, 16/57), center loudspeaker (16/26) and headset sockets (16/111, 16/112). The control module transmits analog signals to these components.

The microphone (16/77) is directly connected to the audio module (AUD). The microphone transmits analog signals to the control module.

When sound compensation is required, the infotainment control module (ICM) transmits sound compensation signals via the MOST network to the audio module (AUD).

Certain versions of the audio module (AUD) can also generate a digital subwoofer signal from the signal transmitted to the audio module (AUD). This signal is then transmitted via the MOST network to the subwoofer module (SUB) (16/79). The signal which is transmitted from the audio module (AUD) to the subwoofer module (SUB) is a summated and filtered loudspeaker signal.

The bass speaker signals are transmitted from the audio module (AUD) on a dedicated channel on the MOST network.

When the MOST network starts after the ignition is switched on, the infotainment control module (ICM) transmits data to the audio module (AUD) indicating whether or not there is a subwoofer module (SUB) available on the MOST network.

SELECTING THE SOUND SOURCE AND TRACK FROM THE HEADSET PANEL

Fig. 60: Identifying Volvo Component Designations
Courtesy of VOLVO CARS CORPORATION

There are two identical button arrangements (16/111, 16/112) on the headset panel, one for each socket. These buttons are used to change the sound source and track.

When a button is pressed on the headset panel, the audio module (AUD) identifies which button it was. This signal is transmitted between the headset panel and the audio module (AUD) on a directly connected cable. The audio module (AUD) (16/105) then sends the data onwards via the MOST network to the infotainment control module (ICM) (16/1) which in turn transmits the data onwards to the selected sound source.

The sound sources which can be selected are:

- radio (ATM) (16/110)
- CD player (MP2) (16/106)
- MD player (MP1) (16/107).

SYSTEM OVERVIEW

AUDIO MODULE (AUD)

The primary task of the audio module (AUD) is to manage the functions for:

- the front, center and rear loudspeakers
- the subwoofer module (SUB)
- the headset, headset panel
- the microphone.

The audio module (AUD) communicates with directly connected components and with other control modules and components via the MOST network, a fiber optic network used for communication.

The audio module (AUD) checks executed activations and input/output signals via its integrated diagnostics. If the control module detects a fault, a diagnostic trouble code is generated. Any diagnostic trouble codes are stored in the control module memory. The information can be read with the help of VIDA via the data link connector in the car.

In order to work correctly on the MOST network, the infotainment control module (ICM) checks that the serial number in the audio module (AUD) is correct. The audio module (AUD) will not function if the number is incorrect. Try switching the ignition off and on if there are problems when replacing the control module.

A simple way to check whether the control module is functioning is to switch on the radio and to then change the volume. The volume from the loudspeakers should rise and fall with the changes.

The Audio module (AUD) is a slave module on the MOST network. The infotainment control module (ICM) is the master control module.

There are three versions of the audio module (AUD):

- Performance
- High Performance
- Premium Sound.

The number of functions and loudspeaker outlets varies between the versions. The power output of the versions is also different.

The control module is under the right-hand front seat.

SIGNALS

The table below summarizes the input signals to and output signals from the audio module (AUD). The signal types are divided into directly connected signals and MOST communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: • Microphone (16/77) analogue signals • Headset panel (16/111, 16/112) analogue control signals.	**Directly connected:** • Headset panel (16/111, 16/112) analogue signals • Loudspeaker left front (16/4, 16/55) • Loudspeaker right front (16/3, 16/56) • Loudspeaker left rear (16/6) • Loudspeaker right rear (16/5) • Treble loudspeaker left D-post (16/57) • Treble loudspeaker right D-post (16/58).
Via MOST communication: • Infotainment Control Module (ICM) (16/1) master control module • Aerial module (ATM) (16/110) • CD module (MP2) (16/106) • MD module (MP1) (16/107) • Phone module (PHM) (16/60) • Multimedia module (MMM) (16/108).	**Via MOST communication:** • Infotainment Control Module (ICM) (16/1) master control module • Subwoofer module (SUB) (16/79) • Phone module (PHM) (16/60) • Multimedia module (MMM) (16/108).

Fig. 61: Identifying Volvo Component Designations
Courtesy of VOLVO CARS CORPORATION

AUDIO MODULE (AUD) (2007-2012)

DESIGN

CONTROL MODULE

Fig. 62: Identifying Audio Module
Courtesy of VOLVO CARS CORPORATION

The audio module is an amplifier which is connected to the MOST network. It has the following functions:

- to carry the sound signal transmitted on the MOST network out to the directly connected loudspeakers and to the headsets as analogue signals
- to carry voice messages from the microphone, out on the MOST network.
- to transmit requests from the headset panel to change to the next or the previous track or to change the sound source.

If there is a subwoofer module installed on the MOST network, the audio module can process the incoming signal and transmit it to the subwoofer module.

The following versions of Audio module are available:

- Headset panel
- Headset panel

Audio module and have 4x40 W output and has 5x130 W.

Each version of the audio module (AUD) has a different number of loudspeakers and different loudspeaker models.

FUNCTIONS IN THE AUDIO MODULE (AUD)

The audio module (AUD) can run a number of different functions, but these functions can also be activated by other nodes. An example of these functions is lowering and increasing the volume. The signal comes from the infotainment control module (ICM), but it is the audio module (AUD) that actually changes the volume. The functions are described below.

1. **Adjustable volume** , raises and lowers the volume
2. **Adjustable bass** , raises and lowers the bass level
3. **Adjustable treble** , raises and lowers the treble level

4. **System generated sound signals** , assist other nodes in the system with single sound signals generated in the control module, for example alarm signals for the park assistance function.
5. **Limiter** , the limiter function in the control module does not permit an increase in the power output level if this leads to a fall in sound quality
6. **Mixing** , mixing allows numerous different sound types to be mixed. In this case, the different sound types are foreground noise, background noise and system generated sound signals. An example of this is where a CD is playing (background noise) and the carphone rings. The ringing signal will be heard through the loudspeakers while the volume of the music drops at the same time
7. **Digital bass loudspeaker output,** via MOST network, transmits signals to Subwoofer module. No foreground noise must be included in the signals.
8. **Bass compensation** , the bass from the control module is compensated or modified depending on the volume level and the speed of the car. If the vehicle speed and volume level changes, the bass compensation is also changed
9. **Treble compensation** , the treble in the control module is compensated or modified depending on how the volume is changed. If the volume changes, the treble compensation also changes
10. **Equalizer setting, sound compensation** , there are different settings for the sound from the audio module. This compensates for factors such as the location of the loudspeakers and the layout of the car interior.
11. a surround decoder for playing sound.

There are two types of sound, foreground sound and background sound. The sounds which are foreground and background are listed below.

Foreground sound:

- navigation
- system generated sound from the audio module
- traffic messages.

Background sound:

- analogue radio, AM/FM
- CD player
- playing sound via the AUX input.

The functions in the different versions of the audio module are:

1. adjustable volume
2. adjustable bass level
3. adjustable treble level
4. system generated sound signals
5. limiter
6. mixing

7. digital bass speaker output
8. bass compensation
9. treble compensation
10. equalizer

1. adjustable volume
2. adjustable bass level
3. adjustable treble level
4. system generated sound signals
5. limiter
6. mixing
7. digital bass speaker output
8. bass compensation
9. treble compensation
10. equalizer
11. DPL2 - Dolby ProLogic II.

LOUDSPEAKERS

Fig. 63: Identifying Loudspeakers
Courtesy of VOLVO CARS CORPORATION

and

For High Performance and High Performance HP, 8 loudspeakers are used. It is a 2 way loudspeaker system with base/mid-range speakers and separate trebles. The speakers are installed in the front and rear doors. There are also 2 speakers installed in the D-posts.

The impedance is 2 ohms for the base/mid-range loudspeakers and 8 ohms for the treble speakers.

For Premium Sound, 9 loudspeakers are used. It is a 2 way loudspeaker system with base/mid-range and separate trebles. The speakers are installed in the front and rear doors. There are also 2 loudspeakers installed in

the D-posts. To increase the sound there is a 2 way central loudspeaker in the dashboard.

The impedance is 4 ohms for the base/mid-range loudspeakers and 8 ohms for the trebles. The center loudspeaker impedance is 6 ohms if a display screen is installed in the dashboard, otherwise the central loudspeaker impedance is 8 ohms.

HEADSET PANEL

Fig. 64: Identifying Headset Panels
Courtesy of VOLVO CARS CORPORATION

The Audio module (AUD) has outputs for connections to the left and right headset panel. The headset panels are located on the inside of the C-post. Each headset panel has a control for volume, next track, previous track and source.

MICROPHONE

Fig. 65: Locating Microphone
Courtesy of VOLVO CARS CORPORATION

The microphone is directly connected to the audio module (AUD). The microphone transmits analog signals to the control module.

Telephone calls can be made either hands free or using the handset. During handsfree calls, the microphone and

speaker are used which are connected to the audio module (AUD). The microphone is phantom fed via the audio module (AUD).

DIAGNOSTIC FUNCTIONS

GENERAL INFORMATION

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. A fault which is detected in the most recent operating cycle is defined as permanent. Other faults which are detected are defined as intermittent.

If for some reason a fault disappears after being stored in the control module as a permanent diagnostic trouble code, the information remains stored in the control module. If a fault is no longer permanent, the diagnostic trouble code remains as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

NOTE: Certain functions are unavailable until the diagnostic trouble codes (DTCs) have been erased.

READING OFF THE PARAMETERS

This function is used to read the status or value of parameters. The status or value can be presented digitally.

READING OFF THE CONTROL MODULE IDENTIFICATION

The diagnostic tool identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N

READING OFF EXTENDED DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION

This function can be used to read parameters, status identifiers and counters stored at the same time as a diagnostic trouble code (DTC). These are called frozen values.

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

GENERAL INFORMATION

New software can be downloaded into the audio module (AUD). When software is ordered the software and hardware of the vehicle are compared with Volvo's central database. If the comparison corresponds then the software is downloaded into the control module.

If the comparison between the car and Volvo's central database does not correspond, then the database is updated with the vehicle's configuration. When this is complete the software is downloaded.

REPLACING THE CONTROL MODULE

The control module is located under the right front seat.

After replacement of the audio module (AUD), the infotainment control module (ICM) checks its unique serial number. If the serial number is incorrect, the audio module (AUD) will not work. If the problem remains after software download, try switching the ignition off/on.

Select the MOST network for a total download of software to the vehicle.

FUNCTION

PLAYING BACK SOUND

Fig. 66: Identifying Volvo Component Designations
Courtesy of VOLVO CARS CORPORATION

All functions in the audio module (AUD) (16/105) are controlled by the signals from other nodes in the MOST network.

To initiate audio playback, a control module transmits a request to the infotainment module (ICM) (16/94). The infotainment control module (ICM) allocates the request to the audio module (AUD) then the control module can transmit data via the MOST network to the audio module (AUD).

The infotainment control module (ICM) processes changes to the volume, balance, bass, treble and equalizer settings. The infotainment control module (ICM) transmits the changes via the MOST network to the audio module (AUD) which then carries out the changes.

The control modules on the MOST network which use the audio module (AUD) to play back sound are:

- multimedia module (MMM) (16/108) for voice guiding (navigation)
- integrated audio module (IAM) (16/1)
- Subwoofer module (SUB) (16/79)
- phone module (PHM) (16/60), handsfree speaker sound.

The audio module (AUD) can generate simple sound signals which are used for example to warn the driver and passengers if there are problems. These signals are transmitted from the infotainment control module (ICM) via

the MOST network to the audio module (AUD).

When the Audio module (AUD) has received optical signals on the MOST network, the signals are transmitted onwards as analog signals to:

- loudspeaker left front (16/4, 16/55)
- loudspeaker right front (16/3, 16/56)
- Loudspeaker left rear (16/6)
- Loudspeaker right rear (16/5)
- loudspeaker left D-post (16/57)
- loudspeaker right D-post (16/58)
- Center loudspeaker (16/26) (option).
- headset panel, left, rear (16/111)
- headset panel, right, rear (16/112).

The microphone (16/77) is directly connected to the audio module (AUD). The microphone transmits analog signals to the control module.

When sound compensation is required, the infotainment control module (ICM) transmits sound compensation signals via the MOST network to the audio module (AUD).

SELECTING THE SOUND SOURCE AND TRACK FROM THE HEADSET PANEL

There are two identical button arrangements (16/111, 16/112) on the headset panel, one for each socket. These buttons are used to change the sound source and track.

When a button is pressed on the headset panel, the audio module (AUD) (16/105) identifies which button it was. This signal is transmitted between the headset panel and the Audio module (AUD) on a directly connected cable. The Audio module (AUD) then transmits information on, via the MOST network, to the Infotainment control module (ICM) (16/94), which, in turn transmits the information on to the selected sound source.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 67: Identifying Audio Module
Courtesy of VOLVO CARS CORPORATION

The most important task of the audio module (AUD) is handling the functions of the front, rear and center speakers and microphone.

If a subwoofer module (SUB) is installed on the MOST network, the audio module (AUD) transmits signals to the subwoofer module (SUB).

The audio module (AUD) communicates with directly connected components and with other control modules and components via the MOST network, a fiber optic network used for communication.

The Audio module (AUD) checks internal components, executed activations and input/output signals via its integrated diagnostics. If the control module detects a fault, a diagnostic trouble code is generated. Any diagnostic trouble codes are stored in the control module memory. The information can be read via the data link connector in the vehicle.

In order to work correctly on the MOST network, the infotainment control module (ICM) checks that the serial number in the audio module (AUD) is correct. The audio module (AUD) will not function if the number is incorrect. Try switching the ignition off and on if there are problems when replacing the control module.

A simple way to check whether the control module is functioning is to switch on the radio and to then change the volume. The volume from the loudspeakers should rise and fall with the changes.

The Audio module is a slave module on the MOST network. The infotainment control module is the master control module.

The following versions of Audio module are available:

- Headset panel
- Headset panel

The number of functions and loudspeaker outlets varies between the versions. The power output of the versions is also different.

The control module is located under the right front seat.

SIGNALS

The table below summarizes the input signals to and output signals from the audio module (AUD). The signal types are divided into directly connected signals and MOST communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: • Power supply • Ground • Microphone (16/77) • Headset panel (control signal) (16/111, 16/112)	**Directly connected:** • Loudspeaker left front (16/4, 16/55) • Loudspeaker right front (16/3, 16/56) • Loudspeaker left rear (16/6) • Loudspeaker right rear (16/5) • Center loudspeaker (16/26) (option). • Loudspeaker left D-post (16/57) • Loudspeaker right D-post (16/58) • Headset panel (16/111, 16/112) • Microphone (16/77) (phantom feed)
Via MOST communication: (ring network) • Infotainment control module (ICM) (16/94), main control module • Integrated audio module (IAM) (16/1) • Phone module (PHM) (16/60) • Multimedia module (MMM) (16/108)	**Via MOST communication:** (ring network) • Infotainment control module (ICM) (16/94), main control module • Multimedia module (MMM) (16/108) • Subwoofer module (SUB) (16/79) • Phone module (PHM) (16/60)

BATTERY (ALL)

DESIGN AND FUNCTION

INTRODUCTION

The battery type used in most cars is usually know as a lead accumulator. These batteries are so named because the electrodes are lead and the role of the battery is to store (accumulate) energy.

A key characteristic of lead accumulators is that they can meet the extreme physical requirements for charging and discharging. Lead accumulators provide optimal performance as both starter and reserve power batteries. Lead accumulators are relatively cheap to produce and can store large amounts of energy. As a result, lead accumulators make up in excess of 50% of the entire battery market.

PRINCIPLE

Fig. 69: Battery Principle
Courtesy of VOLVO CARS CORPORATION

A battery is a unit which stores chemical energy which can then be converted into electrical energy as required. When the battery is connected to an external source of consumption (the car starter motor for example), the stored chemical energy is converted into electrical energy and current flows through the circuit.

The start battery in a car, the lead accumulator, is rechargeable. Such a battery can be recharged repeatedly, whereby electrical energy is converted to chemical energy.

FUNCTION

Fig. 70: Identifying Components Which Require Battery Current
Courtesy of VOLVO CARS CORPORATION

The function of the battery in a car is to supply the car with a stable voltage in all situations. One of the tasks of the battery is to provide a current when starting the engine. Other tasks are to provide a current to components (such as the parking lamps) which require current when the engine is not running (i. e. when the generator (GEN) is not charging). The battery also operates as an energy reserve when the capacity of the generator (GEN) is insufficient and needs to be supplemented.

A BATTERY WORKS AS FOLLOWS

The battery consists of several cells. Schematically, a battery can be said to be made up of two electrodes, one positive and one negative. These electrodes are different materials, which are submerged in a container filled with electrolyte, often called battery acid. As a result of the different electrode materials, there is an electrical charge between the positive and negative electrodes. There is a chemical reaction between the electrodes and the electrolyte causing electrical energy to be generated. If the positive and the negative poles of the electrodes are connected to form a closed circuit, a current flows through the circuit.

In a lead accumulator, the positive electrode consists of lead oxide and the negative electrode of porous lead. The electrolyte consists of diluted sulphuric acid ($H_2 SO_4$) which is a mixture of concentrated sulphuric acid and distilled or deionized water.

BATTERY TYPES

In principle, lead batteries can be divided into two different categories:

- Open batteries
- Sealed batteries

Open batteries

In principle, open batteries have free-hanging plates in the battery box, most often insulated from each other by

the negative plate being located in a small separator bag of polyethylene. The electrolyte is highly viscous and can flow freely between the plates.

A maintenance-free battery is normally an open battery where the design has reduced the gas and also has made the battery box so airtight that any gases stay in place. A lot of acid means that the fluid will last for its service life without topping up.

Sealed batteries (recombination batteries)

For sealed batteries the battery box is designed as a pressure vessel with relief valves and go under the name VRLA (Valve Regulated Lead Acid), that is, valve-controlled lead-acid batteries.

If you shut in the acid and hydrogen gas then these can react with each other and be reformed to water. This is called recombination and is a good way to almost completely eliminate fluid losses. It is not possible to shut in and recycle everything, but it can be reduced significantly. The sealed batteries can be divided into two groups:

- Gel batteries
- AGM-batteries

Gel batteries

A gel battery has a few substances, often silicone compounds, added in the electrolyte so that it gels. Thus there is no free-floating acid that can run out of the battery.

Gel batteries have good capacity, but due to the slightly higher resistance in the low viscosity acid, they may be limited as start batteries. They can handle deep cycle discharges very well, that is, when you slowly discharge the batteries a lot several times.

Gel batteries are very rugged and are often used, e. g., in cleaning machines and golf carts.

The small volume of electrolyte in the battery and that it is low viscosity makes the battery sensitive to dehydration that an overcharge with resulting gas generation could entail.

AGM-batteries

In AGM-batteries the electrolyte is kept in place by the separator paper, consisting of a fibreglass mat (AGM = Absorbed Glass Mat), working as a "sponge". The capillary forces in the separator means that electrolyte ends up in the right place. The batteries can be built with very thin separators, which keeps down the internal resistance. This means that that you can get high power from a small volume, making it perfect as start battery.

The fibreglass mat is quite thin, which makes for a small electrolyte volume in the battery. This makes the battery sensitive to dehydration that an overcharge with resulting gas generation could entail.

PROPERTIES (A FEW TYPICAL PROPERTIES)

Open batteries	
Advantages:	***Disadvantages:***

• Lower price in relation to the current that it can provide. • Low weight in relation to the current that is can provide. • Can handle high charging voltage. • Water can be filled (not maintenance-free batteries).	• Damaged if discharged too much, too many times. • Must be installed standing. • Need periodic maintenance (not maintenance-free batteries). • Higher degree of self-discharge. • Not very vibration-resistant. • Acid may leak out if battery tilts over.
Sealed batteries AGM-batteries	
Advantages: • No maintenance needed during the battery's lifetime. • No gases, no corrosion, no acid spills. • Low degree of self-discharge. • Extremely vibration-resistant. • Withstands several deep-cycle discharges.	***Disadvantages:*** • Higher price in relation to capacity. • Higher weight in relation to capacity. • Requires careful control of charging voltage. • Sensitive to overcharging. • Not possible to fill water.

THE CONSTRUCTION OF THE BATTERY

Fig. 71: Battery Construction
Courtesy of VOLVO CARS CORPORATION

Battery

1. Handle (on certain battery models)
2. Plugs (not maintenance-free as well as AGM-batteries)
3. Positive and negative posts.

The battery is in a plastic container and has six internal chambers, one for each cell. These chambers are not connected to each other. This means that the electrolyte level can drop in one chamber without affecting the level in the other chambers. The cells are connected in series by a sealed joint between each chamber.

On the top of some "open" batteries, there is a cover with six plugs, one for each cell. The plugs can be opened to check electrolyte level and for topping up with battery water. Maintenance-free batteries as well as AGM-batteries do not have these plugs and therefore cannot be topped up with battery water.

The battery is filled with electrolyte. The electrolyte consists of diluted sulphuric acid ($H_2 SO_4$) which is a mixture of concentrated sulphuric acid and distilled or deionized water. Electrolyte is often referred to as battery acid. Electrolyte has a density of 1.28 g/cm^3 when the battery is fully charged.

A battery is built up of two or more cells connected in series depending on which terminal voltage is desired. An open car battery consists of six cells and the terminal voltage of a fully charged battery is 12.72 V, that is 2.12 V per cell. For AGM-batteries, the max. terminal voltage of a fully charged battery is 12.93 V.

The AGM-batteries' container is provided with a safety valve. The purpose is to protect the battery against too high pressure inside the battery. Too high pressure can occur in case of incorrect charging, e. g., with too high voltage.

NOTE: The battery is damaged if the safety valve has been activated.

Evacuation hose (not sealed batteries)

Certain batteries (such as genuine Volvo batteries) have an evacuation hose. This applies to car models where the battery is located in the cargo compartment (not in the engine compartment). The function of the evacuation hose is to lead any gases (oxyhydrogens) that build up in the battery during charging away from the cargo compartment out into the open air.

CAUTION: The evacuation hose must be connected at all times when the battery is connected. Always remember to connect the hose and ensure that the hose is routed downwards to the dedicated outlet in the bodywork when replacing the battery

THE CONSTRUCTION OF THE CELLS

Fig. 72: Construction Of The Cells
Courtesy of VOLVO CARS CORPORATION

The construction of the cells

1. Positive plate in separator
2. Negative plate
3. Positive and negative plate assembly
4. Connection
5. Plate assembly for one cell.

A cells consists of several positive and negative plates. These plates are welded together in groups by plate straps. These plates function as electrodes in the cell. Each positive cell is in a type of isolator, known as a separator. The task of the separator is to separate the positive and negative plates and to catch any particles that have detached from the positive plate, thus preventing short-circuits. Each cell contains a combination of such plates connected in series. The separators consist of an acid resistant plastic.

For AGM-batteries, the pocket separator consists of a thin fibre-glass mat (AGM = Absorbed Glass Mat).

Each plate is made up of a grille with an external layer of active material. This active material contributes to the electrochemical process during charging and discharging. The grille is constructed of a type of a lead alloy which functions as a conductor for the active material and also carries the current. The positive plate has an external layer of lead dioxide, while the external layer on the negative plate consists of porous lead.

The cell is surrounded by electrolyte. This is the final component of a complete cell. Each cell can generate 2.12 V (full charge at 25°C (77°F)).

For AGM-batteries, each cell can generate 2.155 V.

DISCHARGE

Fig. 73: Battery Discharge
Courtesy of VOLVO CARS CORPORATION

The process during discharge

1. Negative plate: Pure lead is converted to lead sulphate
2. Electrolyte: The sulphuric acid is converted to water
3. Positive plate: Lead oxide is converted to lead sulphate
4. Power consuming components.

During discharge, the lead in the negative plate is converted to lead sulphate ($PbSO_4$).

The lead dioxide (PbO_2) in the positive plate is also converted to lead sulphate. During the discharge process, sulphuric acid (H_2 SO_4) is consumed while water (H_2 O) is created. This reduces the density of the electrolyte.

The density drops throughout the discharge process and can be gauged to determine the condition of the battery. The electrolyte in a fully charged battery has a density of 1.28 g/cm^3 . The density of the electrolyte in a fully discharged battery is 1.10 g/cm^3 .

CHARGING

Fig. 74: Battery Charging
Courtesy of VOLVO CARS CORPORATION

The process during charging

1. Negative plate: Lead sulphate is converted to pure lead
2. Electrolyte: Water is converted to sulphuric acid
3. Positive plate: Lead sulphate is converted to lead oxide
4. The power supply from the generator or the external battery charger.

During charging, energy is supplied to the battery. This causes an electro-chemical process that is the reverse of the process during discharge. The lead sulphate ($PbSO_4$) in the negative plate is converted back to pure porous lead (Pb) and the lead sulphate ($PbSO_4$) in the positive plate is converted to lead dioxide (PbO_2).

Water (H_2 O) is consumed during the charging process. Sulphuric acid (H_2 SO_4) is formed. The density of the electrolyte increase as the amount of sulphuric acid increases.

CAUTION: For charging AGM-batteries, use only chargers that are both current and voltage-controlled. AGM-batteries are sensitive to overcharging and must be charged with an adapted charger. This since a battery that is charged with too high voltage/current does not absorb all the energy and the excess is converted to heat. When the battery becomes too warm the electrolyte evaporates (acid). When the pressure in the battery becomes too high, the gas is released through the battery box safety valve. When the water volume decreases the acid concentrates to an unacceptable high level, which may destroy the battery

AGM-batteries may be charged with a max. voltage/current as follows.

Battery capacity (Ah)	Max. current (A) *	Max. voltage (V)	Max. charging time (h)

			**
100 Ah	25 A	14, 4 V	5-24 h
90 Ah	22, 5 A	14, 4 V	5-24 h
80 Ah	20 A	14, 4 V	5-24 h
70 Ah	17, 5 A	14, 4 V	5-24 h
60 Ah	15 A	14, 4 V	5-24 h
50 Ah	12, 5 A	14, 4 V	5-24 h
40 Ah	10 A	14, 4 V	5-24 h
30 Ah	7, 5 A	14, 4 V	5-24 h
20 Ah	5 A	14, 4 V	5-24 h
10 Ah	2, 5 A	14, 4 V	5-24 h
5 Ah	1, 25 A	14, 4 V	5-24 h

* Max. current is calculated with the following formula (Battery capacity Ah/20)*5. For example, for a battery with capacity 70 Ah: (70/20)*5= 17.5 A.

** Charging time depends on how discharged the battery is, however, max. 24 h.

GAS BUILD UP

Fig. 75: Battery Gas Build Up
Courtesy of VOLVO CARS CORPORATION

Gas build up

1. Gas build up at the plates
2. Negative plate
3. Electrolyte
4. Positive plate

5. The power supply from the generator or the external battery charger.

Gas builds up at the end of the charging process when charging a lead battery. When the battery has reached 85-90% of the maximum capacity, the water in the electrolyte begins to separate into oxygen (O_2) and hydrogen (H_2). Oxygen is formed at the positive plate and hydrogen at the negative plate.

Gas build up results in a loss of some of the gas from the battery, because the battery must not be fully sealed. Because the water is lost, the electrolyte level in the battery will drop. New distilled or deionized water must therefore be added to prevent damage to the plates as a result of the electrolyte level being too low. If new water is not added when necessary, the plates may come into contact with the air. This would result in corrosion, reducing the capacity of the battery.

For maintenance-free batteries as well as sealed batteries (AGM), normally no gases are released. This means that the battery water is not consumed in the electrolyte and topping up of battery water is not necessary. Also, the design of the battery box does not permit topping up of battery water.

WARNING: **If oxygen and hydrogen are mixed in the right proportions, oxyhydrogen is formed. This mixture is extremely explosive. Take great care to avoid personal injuries as well as damage to the battery.**

WARNING: **Make sure that the battery charger is turned off before the terminals are disconnected. This to prevent sparking which may ignite the oxyhydrogen.**

NOTE: **Make sure that ventilation is good.**

SELF-DISCHARGE

Fig. 76: Battery Self-Discharge
Courtesy of VOLVO CARS CORPORATION

Example of self-discharge (for open battery type) depending on battery temperature and discharge time

A. Acid density in g/cm^3
B. Number of days that the battery was not under load
C. Acid density at different battery temperatures.

There is always some self-discharge in a battery, when the battery is not in use and during both charging and discharging. If a battery is not used for a longer period, there is considerable self-discharge. The acid density falls and the active material in the plates is converted to lead sulphate. Excessive discharge must be avoided because otherwise there is an increased risk of sulfation. Sulfation may cause permanent damage to the battery. Regular charging of the battery will prevent sulfation. See **SULFATION**. There is an increased risk of damage from freezing in a heavily discharged battery. See **DEEP DISCHARGING**.

The speed of discharge depends on the temperature, time, the condition and construction of the battery. The temperature is particularly influential. The rate of self-discharge is faster at higher temperatures. Batteries should be stored for prolonged periods in a dry, cold place, preferably below freezing.

Ensure that the battery is fully charged if it is to be left unused for a long period. No further charging will be required if the battery is in good condition and is stored in a dry cold place. If the battery is being stored in a warm place, it may require regular charging.

The illustration shows an example of how quickly a battery (of open type) can self-discharge, depending on the temperature of the battery. Note how the density of the acid reduces with time and how the self-discharge speeds up as the temperature increases. For an explanation of the density of the acid, see **ACID DENSITY**.

ACID DENSITY

Fig. 77: Battery Acid Density
Courtesy of VOLVO CARS CORPORATION

Example of the variation in the stand-by voltage and in the density of the acid with the state of charge in a battery (of open type) at +25°C (77°F) (measured after approx. 2 hours charging or discharging)

A. Stand-by voltage in V
B. Acid density in g/cm^3
C. State of charge, SOC, in %
D. Variation in the stand-by voltage with the state of charge
E. Variation in the density of the acid with the state of charge.

The density of the acid is a unit showing the concentration of sulphuric acid in the electrolyte. The density of the acid is a measurement of the battery voltage and, see **STATE OF CHARGE, SOC**. The density of the acid is measured in g/cm^3 . Sulphuric acid is required for the chemical processes in the battery.

The higher the value of the acid (i. e. high concentration of sulphuric acid), the higher the voltage and state of charge. A low acid density value means a correspondingly low concentration of sulphuric acid, low voltage and a reduced capability for providing current. The electrolyte in a fully charged battery has a density of 1.28 g/cm^3 at +25°C (+77°F). The density of the electrolyte in a fully discharged battery is 1.10 g/cm^3 or lower depending on the type of battery.

The illustration shows how the stand-by voltage and the density of the acid drops as the state of charge of a battery reduces.

HINT: For maintenance-free as well as sealed batteries (AGM) the battery acid cannot be accessed and thus its density cannot be measured.

STATE OF CHARGE, SOC

The state of charge (SOC) is expressed as the amount of electrical energy that is stored in the battery at any given time, in relation to how much energy can be stored in a fully charged battery. The state of charge is listed as a percentage of full charge.

CAPACITY

The capacity of a fully charged battery is its ability to give a constant current during a certain time and is stated in the unit ampere-hours (Ah). The time for discharging varies depending on the battery's purpose.

In principle, the capacity is controlled by the plates' area as well as thickness. In a battery there is a big area on the plates, on which chemical reactions can take place, and also where a great amount of electrons (current) can be generated between the plates. This gives them a higher cold-start current value (CCA = Cold Cranking Amperes).

A start battery has big area but thin plates.

For a deep cycle battery, e. g., battery for leisure use, it is important that the chemical process can continue for a long time with lower current use, that is why the plates have to be thick. This gives them many ampere-hours or "spare minutes". Since the plates are thick, they need longer time to charge so that the chemical reaction also takes place deep inside the plates.

For start batteries, 20 hours' capacity (K20) is mentioned. This refers to how much current the battery can

deliver during 20 hours in an ambient temperature of +25°C (+77°F) without the terminal voltage going below 10.5 V.

Example: A battery (of open type) with a stated capacity of 70 Ah should be able to provide a constant current of a max. 3.5 A (3.5 A x 20 h = 70 Ah) for 20 hours.

The capacity of a battery is not only dependent on the size and construction of the battery, but also varies considerably for batteries of the same type with the size of the discharge current. The lower the discharge current the higher the capacity and vice versa. The capacity of the battery is also affected by the temperature and the age of the battery. The nominal value is given at +25°C (+77°F). The capacity of the battery reduces considerably at low temperatures.

The table shows the difference in capacity in a battery at +25°C (+77°F) and -18°C (-0.4°F).

DIFFERENCES IN CAPACITY AT +25°C (+77°F) AND -18°C (-0.4°F)

Capacity at +25°C (+77°F)	Corresponding capacity at -18°C (-0.4°F)
100%	55%
70%	35%
40%	25%

BATTERY SERVICE LIFE

Fig. 78: Battery Service Life
Courtesy of VOLVO CARS CORPORATION

The service life of the battery depends primarily on its construction, maintenance and operating conditions. The following factors may shorten the service life of the battery:

- see **HIGH TEMPERATURES**
- see **CYCLING**
- see **LOW ELECTROLYTE LEVEL**

- see **DEEP DISCHARGING**
- see **INCORRECT CHARGING**
- see **SULFATION**
- see **CORROSION**
- see **VIBRATIONS**

To maintain the best possible service life and capacity, the battery must be maintained and charged in accordance with Volvo's recommendations.

HIGH TEMPERATURES

A high ambient temperature speeds up the chemical processes in the battery during charging and discharging. For every 10°C (18°F) increase in temperature, the reaction speed of the processes doubles. The risk of corrosion, self-discharge and sulfation increase at a high temperature and the service life of the battery is reduced. The service life of a battery improves in colder surroundings.

CYCLING

Cycling means all the discharging and charging in a battery. A battery is always cycling. Discharging, or cycling, can have varying degrees of depth. Deeper discharge is more damaging than lesser discharge. Each discharge results in stress to the plates which deteriorate accordingly. Each instance of cycling cause the material in the plates to become more fragile and ultimately some of this material will separate from the plates. Cycling results in a reduction of capacity.

A lead battery cannot tolerate infinite cycling. Deep discharges should be avoided in order to maintain as long a service life as possible.

LOW ELECTROLYTE LEVEL

The electrolyte level in an open battery (not maintenance-free battery and AGM-batteries) must be checked regularly. The water in the electrolyte is consumed by gas production and absorption. Batteries have different water consumption. This depends on design and ambient temperature. The water is used more quickly in hot climates.

If the electrolyte level is too low, the battery may suffer corrosion and the capacity of the battery may be reduced. Corrosion may occur in the connections between the cells. The consequence may be an open-circuit in a connection which will prevent the battery from supplying a current.

The capacity of the battery is reduced if the electrolyte level is so low that some of the surface of the plates are not submerged in electrolyte. Such surfaces cannot contribute to the chemical processes that occur during charging and discharging.

CAUTION: Note Check the electrolyte level regularly and top up with distilled or deionized water to the indicated maximum marking. Never use tap water

DEEP DISCHARGING

The acid density in a deeply discharged battery is very low (nearly all the sulphuric acid has been consumed and almost pure water remains. There is a high risk that the battery will be damaged beyond repair by freezing at relatively mild temperatures.

The table shows the freezing point of electrolyte in relation to the degree of charge of the battery.

THE FREEZING POINT OF THE BATTERY IN RELATION TO THE DEGREE OF CHARGE

Degree of charge	Freezing point
100 %	approximately -70°C (-94°F)
40 %	approx. -25°C (-13°F)
10 %	approx. -10°C (+14°F)

A deeply discharged battery can also **hydrogenate** .

Hydrogenation

If the discharge is extremely deep, ultimately all the sulphuric acid will be consumed and only water will remain in the electrolyte.

Where lead sulphate is more soluble in water than in sulphuric acid, some of the lead sulphate in the plates will fall into the electrolyte. When the battery is charged, lead will fall on to the negative plates and separators. Lead gathers in small spots on the surface. This can cause short-circuits. This is known as hydrogenation.

INCORRECT CHARGING

Incorrect charging may result in permanent damage to the battery. Incorrect charging may be, for example, charging using a current/voltage that is so strong that the temperature of the electrolyte increases or that the gas development is too powerful.

Increased electrolyte temperature

If charging occurs with an extremely high current, the temperature of the electrolyte will increase considerably as the battery begins to reach full charge. Excessive temperature may damage the materials in the battery and increase the risk of short-circuits.

Intensive gas development

If the gas development during charging is extremely intensive, some of the particles may be forced loose from the active materials on the plates. The plates suffer wear, reducing the service life and capacity. Short-circuits may occur as released particles drop to the bottom of the cell container or cross to the opposite plate.

To ensure optimal performance, always charge batteries according to Volvo's instructions.

CAUTION: For charging AGM-batteries, use only chargers that are both current and voltage-controlled. AGM-batteries are sensitive to overcharging and must be charged with an adapted charger. This since a battery that is charged with too high voltage/current does not absorb all the energy and the

excess is converted to heat. When the battery becomes too warm the electrolyte evaporates (acid). When the pressure in the battery becomes too high, the gas is released through the battery box safety valve. When the water volume decreases the acid concentrates to an unacceptable high level, which may destroy the battery

SULFATION

Fig. 79: Battery Sulfation
Courtesy of VOLVO CARS CORPORATION

Lead sulphate is formed on the plates during discharge. Normally small crystals are formed, which then revert to lead and lead oxide when the battery charges.

In certain circumstances during discharge, *large insoluble* crystals of lead sulphate may be formed. These crystals may form an insulating layer on the plates. This reduces the effective surface of the plates, reducing the contact between the active materials on the plates and the electrolyte. As a result, the capacity of the battery reduces considerably. This is called sulfation and is a result of a battery being left standing for a long period (in excess of two weeks) at a low charge, or because the battery has been under charged repeatedly.

The plates always expand slightly during discharge. If the discharge is very slow, the expansion may be so great that the plates deform or crack. Such damage is permanent and the battery cannot be used again. If a battery has undergone excessive sulfation, it may be possible to renovate the battery by charging the battery slowly using a very low current.

Regular maintenance charging will prevent sulfation.

CORROSION

Batteries may corrode in hot conditions, particularly in countries with hot climates. At high temperatures, the grille in the cell plates corrodes and becomes porous. The connections between the plates may also corrode. The result is a reduction in conductivity and therefore capacity.

VIBRATIONS

The battery is subjected to vibrations if the car is driven on uneven surfaces. Such vibrations can place stress on the inner connections in the battery and cell units, resulting in wear and damage to the battery. This is a rare occurrence in modern cars however.

TERMINOLOGY

AGM-BATTERY

For AGM-batteries, the pocket separator consists of a thin fibre-glass mat (AGM = Absorbed Glass Mat).

See: **SEPARATOR**

ACTIVE MATERIAL

The active material consists of lead oxide in the positive plates and porous lead in the negative plates. The active materials react with the sulphuric acid in the electrolyte during charging and discharging according to the following chemical reaction:

$PbO_2 + Pb + 2\ H_2\ SO_4 = 2\ PbSO_4 + 2\ H_2\ O$

AMPERE (A)

Unit for electrical current. Abbreviated to A.

AMPERE HOURS (AH)

Unit of measurement used to measure the ability of the battery to store electricity or the capacity. The storage capacity is obtained by multiplying the outflowing current in amperes by the discharge time in hours. Ampere hours are abbreviated to Ah.

Example:

A battery that supplies 3 amperes for 20 hours provides 3 A x 20 h = 60 Ah.

BATTERY ACID

Another name for electrolyte. See **ELECTROLYTE**.

BATTERY WATER

Battery water is distilled or deionized water and must be used to top up the battery if the electrolyte level is low. Regular tap water must not be used because it contains substances which may damage the battery.

For maintenance-free batteries as well as sealed batteries (AGM) it is not possible to fill battery water.

CCA

Abbreviation of Cold Cranking Amperes. The, see **COLD CRANKING AMPERES** of a battery is expressed using the CCA value.

CELL

Electro-chemical current producing unit in a battery. Consists of a package with positive and negative plates, separators and electrolyte enclosed in a shell. A fully charged lead battery with a stand-by voltage of 12.72 V has six cells.

CYCLE

In a battery, a cycle consists of a discharge phase and a charge phase.

DIN

An industry norm. Abbreviation of Deutsche Industrie-Norm.

ELECTRICAL CURRENT

A current is a flow of electrodes moving in a cable. It can be compared with a stream of water. Electrical current is measured in amperes (A).

ELECTRODE

An electrode is the place where the chemical reactions during discharge and charge take place. A cell consists of at least one positive and one negative electrode. During discharge, lead oxide is converted to lead sulphate at the positive electrode. At the negative electrode, porous lead is converted to lead sulphate. During charging, the reactions are in the opposite direction; lead dioxide and porous lead are reformed. Electrodes also transport current. In a battery, the electrodes are normally called plates.

ELECTROLYTE

In a lead battery, electrolyte consists of concentrated sulphuric acid and distilled water. Electrolyte is a liquid that conducts current and adds hydrogen and sulphate ions to the electro-chemical reaction during charging and discharging:

$$PbO_2 + Pb + 2\ H_2\ SO_4 = 2\ PbSO_4 + 2\ H_2\ O$$

SEPARATOR

A type of plastic insulator enclosing each positive plate in the cell. The roll of the separator is to separate the positive and negative plates from each other and to catch particles that detach from the positive plate to avoid short-circuits.

For AGM-batteries, the pocket separator consists of a thin fibre-glass mat (AGM = Absorbed Glass Mat).

GRID

A lead alloy frame construction on each plate in the battery. The grid functions as a carrier of the active materials, lead oxide and porous lead, which contribute to the electro-chemical processes during charging and discharging. The grid also conducts the current in the cell.

CAPACITY

The capacity is the ability of a fully charged battery to provide a constant current over a certain time and is given in ampere-hours (Ah). The time taken to discharge depends on the intended use of the battery. For starter batteries one refers to 20 hours capacity (K20). This refers to the amount of current the battery can provide over 20 hours at an ambient temperature of +25°C (+77°F) without the pole voltage falling below 10.5 V.

Example: A battery with a listed capacity of 70 Ah should be able to provide a current of a maximum 3.5 A (3.5A x 20h = 70 Ah) for 20 hours.

CORROSION

A destructive chemical reaction when metal is broken down in an aggressive chemical environment. Sulphuric acid, for example, is aggressive against iron. The iron breaks down and corrodes. The battery terminal is vulnerable to corrosion if it is not maintained correctly.

SHORT-CIRCUIT

A short-circuit is when the current takes a short cut where the resistance is less and therefore does not go via the intended route. A short-circuit can be caused for example by particles detaching from the plates in the cells. Eventually these deposits can be so large that a conductive connection is made between the two plates so that the current can flow between the two plates instead. A short-circuit in a cell can fully discharge a battery and render the battery useless.

COLD CRANKING AMPERES

A measurement of the ability of the battery to start the car. The cold cranking amperage is expressed as a CCA value. Volvo batteries are usually marked with a CCA value according to the SAE norm. The cold cranking amperes according to the SAE norm is defined as the current that a fully charged battery can supply at a temperature of -17.8°C (0°F) for 30 seconds without the voltage dropping below 7.2 V. The higher the cold cranking amperes value, the better the starting capacity of the battery. In certain markets the batteries are marked according to the DIN norm.

CHARGING

The process by which a battery is supplied with energy by a charger or the generator (GEN) in the car. During charging, the lead sulphate in the plates is converted back to pure lead on the negative plates and to lead oxide on the positive plate. Water is consumed, sulphuric acid is formed and the density of the acid increases.

This reaction can be written:

$$2\ PbSO_4 + 2\ H_2O \rightarrow PbO_2 + Pb + 2\ H_2SO_4$$

STATE OF CHARGE, SOC

The state of charge is expressed as the amount of electrical energy that is stored in the battery at any given time, in relation to how much energy can be stored in a fully charged battery. The state of charge is listed as a percentage of full charge. This is the "State of Charge", SOC.

DIRECT CURRENT, DC

An electrical current that only travels in one direction in an electrical cable. A battery supplies direct current during discharge and must be recharged (from the generator (GEN) or an external battery charger) with direct current in the opposite direction to current during discharge.

PLATE

The plates in a battery function as electrodes. Each cells consists of several positive and negative plates. These plates are welded together in groups by plate straps. The plate is made up of a grid with an external layer of active material. This active material contributes to the electrochemical process during charging and discharging. The grid is constructed of a type of a lead alloy which functions as a conductor of the active material and also carries the current. The positive plate has an external layer of lead dioxide, while the external layer on the negative plate consists of porous lead.

PLUG (NOT MAINTENANCE-FREE AS WELL AS AGM-BATTERIES)

On top of the battery is a cover with six plugs, one for each cell. The plugs can be opened when checking and topping up the electrolyte.

RESERVE CAPACITY, RC

The reserve capacity, RC, is measured in minutes and is, according to the SAE norm, the time taken to discharge a fully charged battery at 25 A to a voltage of 10.5 V at a temperature of +25°C (+77°F). The reserve capacity is the length of time the battery is able to supply necessary components with current when the generator (GEN) in the car is not functioning. Volvo batteries are marked with the RC value according to the SAE norm.

SAE

An industry norm. SAE is an abbreviation of "Society of Automotive Engineers".

SEPARATOR

See **SEPARATOR**.

SELF-DISCHARGE

A battery that is not in use will discharge itself over time. This is know as self-discharge and is quicker in hot environments. The battery must be maintained by recharging at regular intervals to avoid excessive discharge.

SULFATION

Sulfation is where, in some circumstances, large insoluble lead sulphate crystals are formed on the plates as the

battery discharges. This reduces the capacity of the battery. Note that the formation of small soluble lead sulphate crystals is normal during discharge.

The plates always expand during discharge. If the discharge is very slow, the expansion may be so great that the plates deform or crack. Such damage is permanent and the battery must be discarded. This is an excessive form of sulfation. The longer the sulfation process continues, the more difficult it is to save the battery.

Sulfation is a result of a battery being left standing for a long period at a low charge, or the battery has been under charged repeatedly. Regular charging of the battery will prevent sulfation.

ACID DENSITY

The unit showing the amount of sulphuric acid in the electrolyte and is a measurement of the battery voltage and charge status. The density of the acid is measured in g/cm^3 . The higher the value of the acid density (i. e. high concentration of sulphuric acid), the higher the voltage and state of charge. A low acid density value means a correspondingly low concentration of sulphuric acid, low voltage and a reduced capability for providing current. The electrolyte in a fully charged battery has a density of 1.28 g/cm^3 . The density of the electrolyte in a fully discharged battery is 1.10 g/cm^3 .

HINT: For maintenance-free as well as sealed batteries (AGM) the battery acid cannot be accessed and thus its density cannot be measured.

DISCHARGE

The process where a battery is under load and gives off current. During discharge, the lead on the negative plate and the lead oxide on the positive plate are converted to lead sulphate. Sulphuric acid is consumed and water is formed, reducing the density of the acid.

This reaction can be written:

$PbO_2 + Pb + 2\ H_2\ SO_4 \text{ --> } 2\ PbSO_4 + 2\ H_2\ O$

STAND-BY VOLTAGE

The stand-by voltage is the voltage measured from an unloaded battery after approximately 2 hours discharging or charging. It is important that the battery is left unloaded for a longer period so that the concentration of sulphuric acid has time to distribute evenly in the electrolyte. The measured voltage is then a good indication of the charge status of the battery.

STAND BY CURRENT CONSUMPTION

The stand by current is the current used by the car when the key is removed (such as the current for the clock, anti-theft alarm and remote control locking).

VOLT (V)

Unit for electrical power. Abbreviated to V.

VOLVO BATTERY ANALYZER 3100

A tool used to test and troubleshoot batteries of open type.

NOTE: Not intended for AGM-batteries.

SURFACE CHARGING

The concentration of sulphuric acid is higher at the plates than in the electrolyte in a battery that has recently been charged. This is because the sulphuric acid formed at the plates during charging has not had time to spread into the rest of the electrolyte. If the stand-by voltage of the battery is measured directly after charging, a higher value will be obtained, giving an incorrect reading of the charge status of the battery. This is called surface charging. If the battery is left without load for a while the concentration of the sulphuric acid will even out. It is therefore important to leave the battery without load for at least 2 hours before measuring the stand-by voltage of the battery, allowing time for the concentration of the sulphuric acid to even out in the electrolyte. The measured voltage is then a good indication of the charge status of the battery.

BLUETOOTH PHONE MODULE (BPM) (2011-2012)

DESIGN

CONTROL MODULE

Fig. 80: Identifying Bluetooth Phone Module (BPM)
Courtesy of VOLVO CARS CORPORATION

The Bluetooth phone module (BPM) has the task of functioning as a wireless link between the vehicle's infotainment system and a cellphone equipped with blue tooth technology.

The Bluetooth phone module (BPM) contains:

- A main processor which manages all functionality and logic for the Bluetooth phone module (BPM). The software for the bluetooth phone module (BPM) is also stored here.
- Sound processor which manages handsfree sound and generates polyphonic ring signals which are then transmitted on to the integrated audio module (IAM) and audio module (AUD) (only certain versions) via

the MOST network.
- Internal blue tooth antenna.

DIAGNOSTIC FUNCTIONS

GENERAL INFORMATION

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored when control module detects a fault. There are approximately 10 diagnostic trouble codes (DTCs) for Bluetooth phone module (BPM). A fault which was detected in the most recent operating cycle is defined as permanent. Other faults are defined as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF THE CONTROL MODULE IDENTIFICATION

The diagnostic tool identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N

READING OFF EXTENDED DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION

This function can be used to read parameters, status identifiers and counters stored at the same time as a diagnostic trouble code (DTC). These are called frozen values.

READING OFF THE PARAMETER VALUES

Using this function, the status or value of parameters can be read off. The status/value is presented digitally.

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

GENERAL INFORMATION

Software can be downloaded to the Bluetooth phone module (BPM). When software is ordered, the vehicle' software and hardware is compared to Volvo's central database. If they are compatible, the software is downloaded to the system.

If the comparison between the vehicle and the Volvo central database does not correspond, the database is updated with the vehicle configuration, and then the software and any security codes (Security access code) is downloaded.

FUNCTION

PHONE

Fig. 81: Identifying Volvo Component Designations
Courtesy of VOLVO CARS CORPORATION

The system is a handsfree system which allows the customer to control their own cellphone from the vehicle and allows the customer to use the vehicle audio system during calls.

The following telephone functions are available via the vehicle's buttons and display when a cellphone is connected to the bluetooth phone module (BPM) via bluetooth:

- Receive incoming calls with number presentation
- End telephone calls

- Initiate telephone calls via normal number dialing
- Searching and initiating telephone calls from the mobile telephone's phone book. In vehicles with model year from and incl. 2012 the Bluetooth phone module (BPM) is equipped with PBAP - Phone Book Access Profile. PBAP is a new standard for faster transfer of the phone book from the customer's mobile telephone to Bluetooth phone module (BPM).
- Accessing last number dialed/received/missed calls on the cellphone
- Activating voice activated function in the cellphone
- Transfer of sound between the vehicle's audio system and the cellphone can occur without interrupting the call.
- A2DP - Advanced Audio Distribution Profile. With A2DP the customer can play back music from their mobile telephone in the car's loudspeakers via Bluetooth phone module (BPM). For vehicles with model year from and incl. 2012.

The Bluetooth phone module (BPM) (16/147) has no keypad of its own for menu management but is either controlled via the keypad on the Climate control module (CCM) (3/112) or via the steering wheel buttons. Climate control module (CCM) transmits the signals for menu management to the infotainment control module (ICM) (3/281) via the CAN network. The infotainment control module (ICM) then transmits the signals onward to the Bluetooth phone module (BPM) via the MOST network.

When using the menu via the steering wheel buttons, information is transmitted from the steering wheel module (SWM) (3/254) to the infotainment control module (ICM) via LIN communication. The information is then transmitted to the Bluetooth phone module (BPM) via the MOST network.

Menu management is displayed for the user in the display for the infotainment control module (ICM). Information is transmitted from the Bluetooth phone module (BPM) to the infotainment control module (ICM) via the MOST network.

When starting the Bluetooth phone module (BPM), receiving incoming calls or when using the phone, a request to use the display will be transmitted to the infotainment control module (ICM).

During conversations via handsfree the microphone and speakers which are connected to the Audio module (AUD) (16/105) and Integrated Audio Module (IAM) (16/1) are used. Bluetooth phone module (BPM) transmits a request to the Infotainment control module (ICM) to receive access to the speakers and microphone. The infotainment control module (ICM) transmits the request onward to the Audio module (AUD) and Integrated Audio Module (IAM). The communication between the Bluetooth phone module (BPM), infotainment control module (ICM), Audio module (AUD) and Integrated Audio Module (IAM) occurs via the MOST network.

MANAGING BLUETOOTH CONNECTIONS

When the system is first activated the customer is led through a pairing process so that the Bluetooth phone module (BPM) and the cellphone recognize and approve each other. This process usually only needs to be carried out once for each cellphone to be used in the vehicle.

The pairing process starts by the Bluetooth phone module (BPM) searching for all nearby blue tooth units. When this search is complete a list is presented for the user with all the cellphones which were found during the

search. The name which occurs in the list can normally be set on the customer's cellphone. Note that the bluetooth function in the cellphone must be active and it must be possible to search for the cellphone for it to appear in the list.

When the customer selects their cellphone in the list the units must exchange identity information with each other. A randomly generated 4 figure code is presented for the user in the display in the infotainment control module (ICM). The code can then be entered in the cellphone to complete the pairing process. If this fails the user can try again.

When the process has been successful, the cellphone automatically connects to the Bluetooth phone module (BPM) and the phone functions become available. If the copying of the phonebook and call lists are supported by the cellphone, these will be automatically transferred to the Bluetooth phone module (BPM) after the devices have been connected.

This process can take a few minutes the first time, and the phonebook is not available during this time.

The next time the customer enters the vehicle with that cellphone it will be connected to the Bluetooth phone module (BPM) automatically. Note that the bluetooth function must be active in the cellphone for the automatic connection to occur. The previously copied phone book is available immediately, but a new copy will be taken in the background to ensure that any changes in the customer phonebook are available.

A total of five phones can be paired to the vehicle at the same time. However only one cellphone can be connected, i. e. can be controlled from the vehicle and connect sound via the vehicle.

On start up, the Bluetooth phone module (BPM) will automatically try to connect the cellphone which was most recently connected to the system. If this cellphone is not detected a list of all paired cellphones and the opportunity to pair a new cellphone is presented to the user. It is then possible to change the connected phone while driving.

It is also possible to remove cellphones from the list of paired phones.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 82: Identifying Bluetooth Phone Module (BPM)

Courtesy of VOLVO CARS CORPORATION

The Bluetooth phone module (BPM) has the task of functioning as a wireless link between the vehicle's infotainment system and the driver's or passenger's cellphone equipped with blue tooth technology.

The following telephone functions are available via the vehicle's buttons and display when a cellphone is connected to the bluetooth phone module (BPM) via bluetooth:

- Receive incoming calls with number presentation
- End telephone calls
- Initiate telephone calls via normal number dialing
- Searching and initiating calls from the cellphone address book
- Accessing last number dialed/received/missed calls on the cellphone
- Activating voice activated function in the cellphone
- Transfer of sound between the vehicle's audio system and the cellphone can occur without interrupting the call.

The Bluetooth phone module (BPM) is located above the glove compartment inside the dashboard.

The Bluetooth phone module (BPM) cannot be combined with the Volvo On Call function.

The Bluetooth phone module (BPM) has serial optical communication with components on the MOST network where the infotainment control module (ICM) is the main control module.

The control module checks activations and input and output signals using an integrated diagnostic system A diagnostic trouble code (DTC) is stored if the control module detects an error. In certain cases the control module replaces the faulty signal with a substitute value.

Any diagnostic trouble codes (DTCs) are stored in the control module memory. This information can be read off using the diagnostic tool via the data link connector (DLC) in the vehicle.

If the Bluetooth phone module (BPM) is not supplied with voltage there will be no communication with the MOST network and the system will shut off.

SIGNALS

The table below summarizes the input signals to and output signals from the Bluetooth phone module (BPM). The signal types are divided into directly connected signals (via bluetooth) and MOST communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Via Bluetooth: • Cellphone	**Via Bluetooth:** • Cellphone
Via MOST communication: • Infotainment control module (ICM) (3/281)	**Via MOST communication:** • Infotainment control module (ICM) (3/281)

• Integrated audio module (IAM) (16/1) (microphone)	• Integrated audio module (IAM) (16/1) (loudspeaker sound) • Audio module (AUD) (16/105) (loudspeaker sound) (only certain versions)

Fig. 83: Identifying Volvo Component Designations

BOSCH ME7.01 ENGINE MANAGEMENT SYSTEM (B5254T2; 2003-2007)

DESIGN

IGNITION SWITCH

Fig. 84: Identifying Ignition Switch And Connector Terminals
Courtesy of VOLVO CARS CORPORATION

The Engine Control Module (ECM) uses the signal from the ignition switch to detect when the ignition key has been turned to position II or III. When the key is in the ignition position (position II) or starting position (position III) a high signal (U_{bat}) is transmitted from the ignition switch to the engine control module (ECM). The engine management system prepares for start-up (for example, temporarily activates the fuel pump (FP) relay). When the flywheel in the engine rotates, the engine speed (RPM) sensor signal is used to keep the fuel pump (FP) relay activated.

The fuse in the fusebox in the passenger compartment supplies current to the ignition switch.

The central electronic module (CEM) can diagnose the ignition switch.

FUEL PUMP CONTROL MODULE (ONLY VEHICLES WITH DEMAND CONTROLLED FUEL PUMPS)

Fig. 85: Fuel Pump Control Module
Courtesy of VOLVO CARS CORPORATION

The fuel pump control module powers the fuel pump and regulates the output of the pump. The fuel pressure changes with the output of the pump.

The fuel pump control module is supplied with battery voltage by the fuel pump (FP) relay and is grounded in

the car body. The fuel pump (FP) relay is controlled by the central electronic module (CEM) when requested by the engine control module (ECM).

The engine cannot be started if the power supply to the fuel pump control module is faulty because the fuel pump will not then be powered.

The fuel pump control module is controlled by the engine control module (ECM) via serial communication. The fuel pump control module then controls the fuel pump by transmitting a PWM voltage on the ground lead for the fuel pump. This means that the voltage drop across the pump changes, and with it the output of the fuel pump. Also, see **FUEL PRESSURE REGULATION (ONLY VEHICLES WITH DEMAND CONTROLLED FUEL PUMPS)**.

There are no diagnostics for the fuel pump control module. The engine control module (ECM) has diagnostics for fuel pressure regulation and the associated components. Also, see **FUEL PRESSURE REGULATION, DIAGNOSTICS** .

The pulse-width modulated (PWM) signal from the engine control module (ECM) to the fuel pump control module can be read using VIDA (Volvo scan tool).

The fuel pump control module is on the outside on the right-hand side of the fuel tank.

FUEL PUMP (ONLY VEHICLES WITH DEMAND CONTROLLED FUEL PUMPS)

Fig. 86: Fuel Pump
Courtesy of VOLVO CARS CORPORATION

The function of the fuel pump is to ensure that the pressure is correct at the delivery lines for the injectors when requested by the fuel pump control module.

The fuel pump consists of:

1. An electrical pump with an integrated safety valve
2. A pressure equalization valve. This valve equalizes rapid pressure peaks which occur, for example, when the injectors close during engine braking. It also contains a non-return valve which ensures that the pressure in the system does not drop when the engine is switched off

3. Fuel level sensor
4. Fuel filter, cannot be replaced separately
5. Relief valve, releases fuel into the pump housing
6. Ejector pump, continuously fills the pump housing with fuel. The fuel always flows from the fuel pump through the ejector and back to the pump housing.

The fuel pump is supplied with battery voltage by the fuel pump control module and is grounded in the car body.

The engine control module (ECM) has diagnostics for the fuel pump function to ensure that the pressure is correct. Also, see **FUEL PRESSURE REGULATION, DIAGNOSTICS** .

The fuel pump can be activated and its status read off using VIDA (Volvo scan tool).

The pressure in the fuel rail can be measured by connecting a manometer to a nipple. This nipple is on the right-hand end of the fuel rail.

BRAKE LIGHT SWITCH

Fig. 87: Brake Light Switch
Courtesy of VOLVO CARS CORPORATION

The task of the brake light switch is to provide the engine control module (ECM) with information about the

position of the brake pedal.

A signal is transmitted to the engine control module (ECM) when the brake pedal is pressed. The engine control module (ECM) disengages the cruise control (if activated). The brake pedal sensor also disengages cruise control.

The brake light switch is supplied with power from the ignition switch (terminal 30). When the brake pedal is depressed the switch closes and a high signal (12 V) is transmitted to the engine control module (ECM).

The engine control module (ECM) can diagnose the brake light switch. The status of the switch can be read using VIDA (Volvo scan tool).

The brake light switch is on the pedal box by the brake pedal.

CLUTCH PEDAL SENSOR (MANUAL TRANSMISSIONS ONLY)

Fig. 88: Clutch Pedal Sensor
Courtesy of VOLVO CARS CORPORATION

The clutch pedal sensor provides the Engine Control Module (ECM) with information about the position of the clutch pedal.

This information is used by the control module to switch off the cruise control.

The sensor signal is also used by the control module to prevent engine start if the clutch pedal is not pressed (certain markets).

The sensor consists of a sliding potentiometer which is supplied with power by the control module (signal) and which is grounded in the control module.

The resistance in the sensor drops when the clutch pedal is pressed.

The engine control module (ECM) can diagnose the clutch pedal sensor. The status (position) of the sensor can be read using VIDA (Volvo scan tool).

The sensor is on the pedal box by the clutch pedal.

AIR CONDITIONING (A/C) PRESSURE SENSOR

Fig. 89: Air Conditioning Compressor
Courtesy of VOLVO CARS CORPORATION

The air conditioning (A/C) pressure sensor detects the pressure in the high-pressure side of the air conditioning (A/C) system. This is so the engine control module (ECM) can control:

- engine cooling fan (FC) start
- stopping the compressor if the pressure in the air conditioning (A/C) is too high
- constant idle speed compensation for the air conditioning (A/C) compressor load.

The sensor is linear. It is grounded in the control module and supplied with a 5 Volt current from the control module. A linear signal (between 0-5 V depending on the pressure in the air conditioning (A/C)) is transmitted to the control module. At 0.25 kPa or lower, the voltage is 0 V, at 3100 kPa the voltage is approximately 4.75 V. Low pressure results in low voltage, high pressure in high voltage.

The engine control module (ECM) can diagnose the air conditioning (A/C) pressure sensor. The sensor value can be read off using VIDA (Volvo scan tool).

The air conditioning (A/C) pressure sensor is positioned on the high pressure delivery line for the air conditioning (A/C) system.

HEATED OXYGEN SENSORS (HO2S)

- 5 cylinder engines have two heated oxygen sensors (HO2S), front and rear
- 6 cylinder engines have four heated oxygen sensors (HO2S), front and rear for bank 1 (cylinders 1-3) and front and rear for bank 2 (cylinders 4-6)
- XC90s with 6 cylinder engines utilize the Y-concept, where the engine has two heated oxygen sensors (HO2S) bank 1 (cyl. 1 -3), bank 2 (cyl. 4 -6) and a rear heated oxygen sensor (HO2S) (bank 1).

Front heated oxygen sensor (HO2S)

Fig. 90: Front Heated Oxygen Sensor
Courtesy of VOLVO CARS CORPORATION

The front heated oxygen sensor (HO2S) is used to provide the Engine Control Module (ECM) with information about the remaining oxygen content of the exhaust gases in front of the three-way catalytic converter (TWC). This is so that the Engine Control Module (ECM) can continually check the combustion so that lambda=1. lambda=1 is the ideal fuel-air ratio, with 14.7 kg air/1 kg fuel.

The heated oxygen sensor uses current regulation and its signal characteristic is linear. With a linear signal characteristic, the amplitude of the signal curve is low when changing the oxygen content in the exhaust gases. The probe consists of a preheating element (see "Pre-heating heated oxygen sensors (HO2S)") and the actual lambda sensor. The lambda sensor is an oxygen sensitive ceramic body consisting of zirconium oxide. The control module supplies power to the ceramic body, which reacts to the oxygen content of the exhaust gases. This in turn affects the signal to the engine control module (ECM). In order to determine the oxygen content in the exhaust pipe, the heated oxygen sensor needs reference air from the surrounding air. This reference air reaches the heated oxygen sensor via the wiring.

CAUTION: The wiring for the heated oxygen sensors (HO2S) must not be trapped or damaged in any way. The connectors for the heated oxygen sensors (HO2S) must not be greased under any circumstances. The oil in the grease would disrupt the reference air and the function of the heated oxygen sensors (HO2S).

The engine control module (ECM) can diagnose the heated oxygen sensor. For further information, see

HEATED OXYGEN SENSOR (HO2S) DIAGNOSTIC . VIDA can be used to read off the calculated lambda value from the heated oxygen sensor.

Rear heated oxygen sensor (HO2S)

Fig. 91: Identifying Rear Heated Oxygen Sensor
Courtesy of VOLVO CARS CORPORATION

The rear heated oxygen sensor (HO2S) is used to provide the Engine Control Module (ECM) with information about the remaining oxygen content of the exhaust gases beyond the three-way catalytic converter (TWC). This information is used by the Engine Control Module (ECM) to check the function of the three-way catalytic converter (TWC). This check is carried out when the conditions for the catalytic converter diagnostics have been met. The rear heated oxygen sensor (HO2S) has no direct effect on regulation of the fuel/air mixture. However the Engine Control Module (ECM) uses the signal to optimize the signal from the front heated oxygen sensor (HO2S).

See **CATALYTIC CONVERTER DIAGNOSTIC** .

The heated oxygen sensor (HO2S) uses voltage control. The signal characteristic is binary. With a binary signal characteristic, the amplitude of the signal curve changes considerably when changing the oxygen content in the exhaust gases. Otherwise its components and function are the same as the front heated oxygen sensor (HO2S).

CAUTION: The wiring for the heated oxygen sensors (HO2S) must not be trapped or

damaged in any way. The connectors for the heated oxygen sensors (HO2S) must not be greased under any circumstances. The oil in the grease would disrupt the reference air and the function of the heated oxygen sensors (HO2S).

The engine control module (ECM) can diagnose the rear heated oxygen sensor. The signal can be read using VIDA (Volvo scan tool).

Preheating of the heated oxygen sensors (HO2S)

The heated oxygen sensor (HO2S) only functions above a certain temperature, approximately 300 °C. The normal operating temperature is between 300-900 °C. The heated oxygen sensors (HO2S) are electrically pre-heated so that operating temperature is rapidly reached. This also ensures that the heated oxygen sensors (HO2S) maintain a normal operating temperature and to prevent condensation which could damage the heated oxygen sensor (HO2S).

The heater element in the probe consists of a positive temperature coefficient (PTC) resistor. The system relay supplies the heater element with voltage. The element is grounded in the engine control module (ECM). When the control module grounds the connection a current flows through the PTC resistor. When the heated oxygen sensor (HO2S) is cold, the resistance in the PTC resistor is low and a large current will flow through the circuit. The current from the Engine Control Module (ECM) is pulsed at first to prevent condensation damage to the heated oxygen sensor (HO2S). Depending on the temperature, allowances are made for factors such as the dew point. As the temperature in the PTC resistor rises, the resistance rises, the current falls and switches in stages to a constant current. The pre-heating time for the front heated oxygen sensor (HO2S) is short, approximately 20 seconds.

Probe preheating begins as soon as the engine is started. The heater element heats the heated oxygen sensors (HO2S) to approximately 350 °C. The probes maintain this as a minimum temperature.

The engine control module (ECM) can diagnose the heater element.

ENGINE COOLANT TEMPERATURE (ECT) SENSOR

Fig. 92: Engine Coolant Temperature Sensor
Courtesy of VOLVO CARS CORPORATION

The engine coolant temperature (ECT) sensor checks the temperature of the engine coolant. The temperature of the engine coolant is required so that the engine control module (ECM) can regulate:

- the injection period
- the idle speed
- the engine cooling fan (FC)
- the ignition advance
- engagement and disengagement of the A/C compressor
- diagnostic functions.

The sensor is a negative temperature coefficient (NTC) type which is supplied with power from the control module (signal) and is grounded in the control module.

The resistance in the sensor changes depending on the temperature of the coolant. Depending on the resistance in the sensor, a voltage (signal) is transmitted to the Engine Control Module (ECM). At 0 °C, the voltage is approximately 4.0 V. At 100 °C the voltage is approximately 0.5 V. Low temperature results in high voltage (high resistance), high temperature in low voltage (low resistance).

The engine coolant temperature (ECT) sensor is located beside the thermostat.

The engine control module (ECM) can diagnose the engine coolant temperature sensor. The sensor value can be read off using VIDA (Volvo scan tool).

ENGINE COOLING FAN (FC) / ENGINE COOLING FAN (FC) CONTROL MODULE

Fig. 93: Engine Cooling Fan And Control Module
Courtesy of VOLVO CARS CORPORATION

The engine cooling fan (FC) has two functions. One is to cool the engine compartment, the other is to cool the

condenser when the air conditioning (A/C) compressor is working.

The engine control module (ECM) transmits a pulse width modulated (PWM) signal to the engine cooling fan (FC) control module. The control module then activates the fan at different speeds. The speed of the engine cooling fan (FC) is determined by the engine control module (ECM), depending on the coolant temperature (based on the signal from the engine coolant temperature (ECT) sensor) and the vehicle speed.

The temperature conditions for engagement of the different engine cooling fan (FC) stages may vary slightly, depending on the engine variant and the equipment level.

The temperature conditions apply when:

- the A/C is off
- no faults are detected by the Engine Control Module (ECM).

NOTE: The engine cooling fan may have a post-run of up to approx. 6 minutes after the engine has been turned off. The time for the fan's post-run depends on engine temperature, temperature in the engine compartment and pressure level in the AC-system.

WARNING: Be careful since the engine cooling fan may have a post-run after the engine has been turned off.

The engine cooling fan (FC) and its control module are behind the radiator.

The engine control module (ECM) can diagnose the engine cooling fan. The fan can be activated using VIDA (Volvo scan tool).

COOLING FAN FOR CONTROL MODULES, TURBOCHARGER (TC) (CERTAIN MARKETS ONLY)

Fig. 94: Cooling Fan For Control Modules
Courtesy of VOLVO CARS CORPORATION

The function of the cooling fan is to cool the control modules in the control module box in the engine

compartment. The control modules may be damaged if they overheat.

The engine control module (ECM) activates the fan depending on the signal from the engine coolant temperature (ECT) sensor and the temperature sensor in the control module.

The cooling fan is in the hose between the control module box and the firewall.

The engine control module (ECM) can diagnose the cooling fan. The fan can be activated using VIDA (Volvo scan tool).

A diagnostic trouble code (DTC) is stored if the temperature in the engine control module (ECM) gets too high.

MASS AIR FLOW (MAF) SENSOR (2002-2004)

Fig. 95: Identifying Mass Air Flow Sensor
Courtesy of VOLVO CARS CORPORATION

The mass air flow (MAF) sensor gauges the air mass sucked into the engine. It continuously transmits signals to the engine control module (ECM) about the mass of the intake air. This data is used by the engine control module (ECM) to calculate:

- the injection period
- the ignition timing
- turbocharger (TC) boost pressure (turbocharged engines only)
- the engine load.

The transmission control module (TCM) also uses this data for its gear shift calculations. This data is transmitted to the transmission control module (TCM) from the engine control module (ECM) via the high speed side of the Controller area network (CAN).

The mass air flow (MAF) sensor consists of a plastic housing with connectors, test electronics and an aluminum heat sink. The test electronics in the mass air flow (MAF) sensor consist of a hot film comprised of four resistors. The hot film is cooled by the air flow to the engine.

The mass air flow (MAF) sensor is supplied with battery voltage by the system relay and is grounded in the

engine control module (ECM). The signal from the sensor is analogue and varies between approximately 1-5 V depending on the air mass. Low air flow (low mass) results in low voltage, high air flow (high mass) gives high voltage. No air flow gives a reading of approximately 1 V.

The mass air flow (MAF) sensor is positioned between the air cleaner (ACL) housing and the intake manifold.

The shape of the mass air flow (MAF) sensor is slightly different on naturally aspirated engines and also contains an air temperature sensor.

The engine control module (ECM) can diagnose the mass air flow (MAF) sensor. The signal can be read using VIDA (Volvo scan tool).

MASS AIR FLOW (MAF) SENSOR (2005-)

Fig. 96: Identifying Mass Air Flow Sensor
Courtesy of VOLVO CARS CORPORATION

The mass air flow (MAF) sensor measures the air mass sucked into the engine. On naturally aspirated engines and 5 cylinder turbocharged engines (except B5254T2/-T4), it also measures the temperature of the intake air.

Air mass

The mass air flow (MAF) sensor transmits signals to the engine control module (ECM) about the mass of the intake air. This data is used by the engine control module (ECM) to calculate:

- the injection period
- the ignition timing
- turbocharger (TC) boost pressure (turbocharged engines only)
- the engine load.

The transmission control module (TCM) also uses this data for its gear shift calculations. This data is transmitted to the transmission control module (TCM) from the engine control module (ECM) via the high speed side of the Controller area network (CAN).

The mass air flow (MAF) sensor consists of a plastic housing with connectors, test electronics and an aluminum

heat sink. The test electronics in the mass air flow (MAF) sensor consist of a hot film comprised of four resistors. The hot film is cooled by the air flow to the engine.

The mass air flow (MAF) sensor is supplied with battery voltage by the system relay and is grounded in the engine control module (ECM). The signal from the sensor is analogue and varies between approximately 1-5 V depending on the air mass. Low air flow (low mass) results in low voltage, high air flow (high mass) gives high voltage. No air flow gives a reading of approximately 1 V.

Intake temperature

The temperature sensor detects the temperature of the intake air after the charge air cooler (CAC). This data is used by the engine control module (ECM) to calculate the boost pressure control (turbocharger (TC) and to calculate the injection period. The control module also controls certain diagnostic functions using the signal from the temperature sensor.

The sensor, which is an NTC resistor, is grounded in the control module and supplied with power (signal) from the control module. The resistance in the sensor changes according to the temperature of the intake air. This provides the control module with a signal of between 0-5 V. The lower the temperature the higher the voltage (high resistance). A high temperature results in low voltage (low resistance).

The mass air flow (MAF) sensor is positioned between the air cleaner (ACL) housing and the intake manifold.

The engine control module (ECM) can diagnose the air mass and intake temperature of the mass air flow sensor. The signals can be read using VIDA (Volvo scan tool).

MANIFOLD ABSOLUTE PRESSURE (MAP) SENSOR, INTAKE (TURBOCHARGED ENGINES ONLY, 2002-2004)

Fig. 97: Manifold Absolute Pressure Sensor - Intake (Turbocharged Engines Only, 2002-2004)
Courtesy of VOLVO CARS CORPORATION

The manifold absolute pressure (MAP) sensor detects the pressure in the intake manifold downstream of the charge air cooler (CAC). The signal from the sensor is primarily used by the engine control module (ECM) to check that the correct boost pressure is reached. The boost pressure is governed by the turbocharger (TC) control valve.

The sensor, which is a piezo resistor, is grounded in the control module and supplied with 5 V from the control

module.

The resistance in the sensor changes depending on the pressure in the intake manifold, giving a signal of 0 -5 V. Low pressure results in low voltage, high pressure in high voltage.

The engine control module (ECM) can diagnose the manifold absolute pressure sensor. The sensor signal can be read using VIDA (Volvo scan tool).

The manifold absolute pressure (MAP) sensor is in the intake hose for the throttle body (TB).

MANIFOLD ABSOLUTE PRESSURE (MAP) SENSOR, INTAKE (TURBOCHARGED ENGINES ONLY, 2005-)

Fig. 98: Manifold Absolute Pressure Sensor - Intake (Turbocharged Engines Only, 2005-)
Courtesy of VOLVO CARS CORPORATION

The manifold absolute pressure (MAP) sensor detects the pressure in the intake manifold downstream of the charge air cooler (CAC). On 6 cylinder turbocharged engines and B5254T2/-T4, the temperature of the intake air is also detected.

Pressure sensor

The signal from the sensor is primarily used by the engine control module (ECM) to check that the correct boost pressure is reached. The boost pressure is governed by the turbocharger (TC) control valve.

The sensor, which is a piezo resistor, is grounded in the control module and supplied with 5 V from the control module.

The resistance in the sensor changes depending on the pressure in the intake manifold, giving a signal of 0 -5 V. Low pressure results in low voltage, high pressure in high voltage.

Intake temperature

The temperature sensor detects the temperature of the intake air after the charge air cooler (CAC). This data is used by the engine control module (ECM) to calculate the boost pressure control (turbocharger (TC) and to calculate the injection period. The control module also controls certain diagnostic functions using the signal from the temperature sensor.

The sensor, which is an NTC resistor, is grounded in the control module and supplied with power (signal) from the control module.

The resistance in the sensor changes according to the temperature of the intake air. This provides the control module with a signal of between 0-5 V. The lower the temperature the higher the voltage (high resistance). A high temperature results in low voltage (low resistance).

The engine control module (ECM) can diagnose the manifold absolute pressure sensor. The sensor signal can be read using VIDA (Volvo scan tool).

The manifold absolute pressure (MAP) sensor is in the intake hose for the throttle body (TB).

LEAK DIAGNOSTIC UNIT (CERTAIN MARKETS ONLY)

Fig. 99: Identifying Leak Diagnostic Unit
Courtesy of VOLVO CARS CORPORATION

The function of the leak diagnostic unit is to pressurize the fuel tank system during leak diagnostics.

The leak diagnostic unit consists of a plastic housing with:

1. electrical air pump
2. a valve / solenoid which governs the air flow in the unit
3. a heater element (PTC resistor) which warms up the pump.

The electrical pump, valve and heater element in the unit are supplied with voltage by the system relay. The pump, valve and heater element are grounded (control) in the engine control module (ECM).

NOTE: On model years, 2002-2004 the heating element was controlled by the Central electronic module (CEM), but on request from the Engine control module (ECM).

During leak diagnostics the pump in the leak diagnostic unit starts. The valve in the unit is operated by the engine control module (ECM) by grounding the different circuits internally in the engine control module (ECM).

The Engine control module (ECM) checks the fuel tanks system for leaks by pressurizing the system and at the same time monitoring a number of relevant parameters. See : **LEAK DIAGNOSTICS (CERTAIN MARKETS ONLY)**

The engine control module (ECM) can diagnose the leak diagnostic unit.

The valve in the leak diagnostic unit can be activated.

The leak diagnostic unit is at the upper front edge of the fuel tank.

OUTSIDE TEMPERATURE SENSOR

Fig. 100: Identifying Outside Temperature Sensor
Courtesy of VOLVO CARS CORPORATION

The outside temperature sensor detects the temperature in the surrounding air. The signal is used by the engine control module (ECM) as a substitute value in the event of a fault in certain components or functions and to control certain diagnostic functions.

The sensor is a negative temperature coefficient (NTC) type which is supplied with power from the control module (signal) and is grounded in the control module.

The resistance in the sensor, which provides a signal between 0-5 V, changes depending on the outside temperature. Low temperatures produce high voltage (high resistance), high temperatures produce low voltage (low resistance).

The outside temperature sensor is positioned in the left door mirror.

The engine control module (ECM) can diagnose the outside temperature sensor. The sensor value can be read off using VIDA (Volvo scan tool).

ENGINE SPEED (RPM) SENSOR

Fig. 101: Engine Speed Sensor
Courtesy of VOLVO CARS CORPORATION

The engine speed (RPM) sensor provides the Engine Control Module (ECM) with information about the speed and position of the crankshaft. The Engine Control Module (ECM) is able to use the signal from the engine speed (RPM) sensor to determine when a piston is approaching top dead center (TDC). However it is unable to use the signal from the engine speed (RPM) sensor to determine whether the piston is in the combustion stroke or whether the exhaust valve is open (exhaust stroke). The signal from the camshaft position (CMP) sensor is also required to determine the operating cycle of the engine.

The signal from the engine speed (RPM) sensor is also used to check the engine for misfires. For further information, see **MISFIRE DIAGNOSTICS** .

Cars with manual transmissions have a series of holes drilled in the periphery of the flywheel. Cars with automatic transmissions have a steel ring with punched holes. This steel ring is welded to the edge of the carrier plate. In both cases, there is 6° between each hole. This arrangement creates a hole for each tooth. There are 360° in one revolution. 6° between each hole means that there are 60 holes. However one hole is not drilled/punched, to create a reference position (tooth) for the crankshaft. This reference position is 72° before the top dead center (TDC) of cylinder 1 on a 5 cylinder engine.

The engine speed (RPM) sensor is at the rear of the engine above the flywheel.

The sensor is inductive with a permanent magnet. An alternating current is induced in the sensor when the flywheel/carrier plate passes the engine speed (RPM) sensor. The generated voltage and frequency increases with the engine speed (RPM). The signal varies between 0.1-100 V depending on the engine speed (RPM).

The Engine Control Module (ECM) is able to determine the engine speed (RPM) by counting the number of holes per time unit. When the reference tooth passes the engine speed (RPM) sensor, the voltage and frequency drop momentarily to zero, even though the engine is still running. This allows the engine control module (ECM) to determine the position of the crankshaft.

The following applies to model year 2002 onwards:

If the signal from the engine speed (RPM) sensor is incorrect or missing, the control module will use the signals from the camshaft position (CMP) sensor, on the condition that the position of the camshaft has been adapted and the car can be driven if there is no signal.

The engine control module (ECM) can diagnose the engine speed (RPM) sensor. The sensor value (engine speed (RPM)) can be read off using VIDA (Volvo scan tool).

CAMSHAFT SENSOR

Fig. 102: Camshaft Sensor
Courtesy of VOLVO CARS CORPORATION

The function of the camshaft position (CMP) sensor is to detect the camshaft flanks. The signal from the sensor is used by the engine control module (ECM) to determine the radial position of the camshaft.

Each camshaft has four flanks per camshaft revolution. A pulse wheel on the camshaft consisting of four teeth (the teeth are positioned by each flank) is used by the camshaft position sensor (CMP) to detect the flanks.

The flanks are not symmetric on the camshaft. This allows the control module to determine which flank has been detected and therefore which operating cycle the camshaft is in.

When the operating cycle of the camshaft is established, the control module is able to determine which cylinder should be ignited. In the event of misfire or engine knock, the control module is also able to determine which cylinder is misfiring or knocking. Also, see **KNOCK SENSOR (KS)** and **ENGINE SPEED (RPM) SENSOR**.

Data about the position of the camshaft is used during camshaft control (CVVT). See **CAMSHAFT CONTROL (CVVT)**.

The sensor, which is a magnetic resistor with a permanent magnet, is grounded in the control module and supplied with 5 V from the control module. When one of the teeth on the camshaft pulse wheel passes the camshaft position (CMP) sensor, a signal is transmitted to the control module from the camshaft position (CMP) sensor. The signal varies between 0-1 V and is low when a flank passes the camshaft position (CMP) sensor.

The camshaft position (CMP) sensor is positioned at the rear of the engine by the controllable camshaft (CVVT).

The engine control module (ECM) can diagnose the camshaft position (CMP) sensor.

KNOCK SENSOR (KS)

Fig. 103: Identifying Knock Sensor
Courtesy of VOLVO CARS CORPORATION

The function of the knock sensor (KS) is to monitor combustion knocking from the engine. Knocking may damage the engine and reduces the efficiency of engine combustion.

If the engine control module (ECM) registers knocking from any of the cylinders, the ignition will be retarded for that cylinder at the next combustion stage. If repeated ignition retardation does not prevent knocking, the injection period will be increased. This has a cooling effect. On turbocharged engines the boost pressure will also be lowered, reducing the engine load.

The sensor is made up of a Piezo electrical crystal. If there is engine knock, vibrations (sound waves) spread through the cylinder block to the knock sensor (KS). The resultant mechanical stress in the piezo electrical material in the knock sensors generates a voltage. This signal is transmitted to the engine control module (ECM). The signal corresponds to the frequency and amplitude of the sound waves. This allows the Engine Control Module (ECM) to determine if the engine is knocking. The camshaft position (CMP) sensor and engine speed (RPM) sensor are used to determine the operating cycle of the engine (which cylinder is igniting) and thereby which cylinder is knocking.

The knock sensors (KS) are positioned on the cylinder block below the intake manifold.

The engine control module (ECM) can diagnose the knock sensors (KS).

ELECTRONIC THROTTLE UNIT

Fig. 104: Electronic Throttle Unit
Courtesy of VOLVO CARS CORPORATION

The electronic throttle unit, using the control signal from the engine control module (ECM), regulates the amount of air for engine combustion. This is done using an electronic shutter.

The electronic throttle unit consists of a round throttle disc on a shaft. This is turned using a DC motor (damper motor), gear wheel and two springs, an opening spring and a return spring. The damper motor is controlled by the engine control module (ECM) and is supplied with power by an integrated power stage in the control module. At one of the limit positions the throttle disc is closed so that no air can pass the throttle unit. At the other limit position the throttle disc is parallel to the air flow so that the air is able to freely pass through the throttle unit. The throttle disc shaft is mechanically connected to two built-in potentiometers (position sensors) which are supplied with power by the control module. The signals from the potentiometers provide the control module with data about the position of the throttle disc. The electronic throttle unit has a connector with six gold plated pins.

NOTE: A damaged terminal pin surface can interfere with the function

1. Current channels, potentiometers
2. Contact strips, potentiometers
3. Spring
4. Spring

5. Throttle disc
6. Damper motor
7. Gear wheel
8. Gear sector
9. Connector.

The electronic throttle unit is located on the engine intake manifold.

In the event of a fault, the throttle unit must be replaced as a single unit.

The engine control module (ECM) can diagnose the electronic throttle unit.

THROTTLE POSITION (TP) SENSOR

See **ELECTRONIC THROTTLE UNIT**.

ACCELERATOR PEDAL (AP) POSITION SENSOR

Fig. 105: Accelerator Pedal Position Sensor
Courtesy of VOLVO CARS CORPORATION

The function of the accelerator pedal (AP) position sensor is to provide the engine control module (ECM) with information about the position of the accelerator pedal. This data is used by the control module to deploy the shutter in the throttle unit to the correct angle.

The sensor consists of a plastic housing with two potentiometers, an Analog/Digital converter and circuits. The potentiometers are connected to a shaft which is affected by the position of the accelerator pedal (AP). The resistance in the potentiometers changes with the position of the accelerator pedal (AP).

The accelerator pedal (AP) position sensor transmits an analogue and a digital signal (pulse width modulated (PWM) signal) to the control module. These signals indicate the position of the accelerator pedal (AP). The digital signal is generated by the sensors Analog/Digital converter.

The analog and digital signals are used at the same time by the control module to regulate the throttle shutter

angle.

The sensor is supplied with 12 V by the system relay via a fuse and is grounded to the body.

The digital signal is also used in conjunction with the analog signal for accelerator pedal position sensor diagnostics. The accelerator pedal (AP) position sensor signals can be read off using VIDA (Volvo scan tool). A diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects a difference between the analog and digital signals. The engine control module (ECM) then uses a minimal value to ensure the function (limp home).

The accelerator pedal (AP) position sensor is located on the accelerator pedal bracket.

ENGINE COOLANT LEVEL SENSOR

Fig. 106: Engine Coolant Level Sensor
Courtesy of VOLVO CARS CORPORATION

The function of the engine coolant level sensor is to alert the driver if the engine coolant level in the expansion tank is too low.

The sensor is a magnetic reed switch, which is enclosed in a pipe on the bottom of the expansion tank. Around the pipe, on the inside of the expansion tank is a float. This float contains a magnet. When the engine coolant level is above minimum, the float is too high in the tank to affect the switch. However if the engine coolant level falls below the minimum level, the magnetic field acts on the switch.

The sensor is supplied with voltage (signal) from the Engine Control Module (ECM) and grounded in chassis. When the engine coolant level in the expansion tank is over a certain level the circuit closes, which produces a low signal. When the engine coolant level is below a certain level the circuit is opened by the engine coolant level sensor, which produces a high signal. When the engine control module (ECM) detects a high signal the information about low engine coolant level is transmitted via the Controller area network (CAN) to the driver information module (DIM), which warns the driver.

NOTE: There are no functions controlled by the engine which are directly connected to the low coolant level warning lamp. The Engine Control Module (ECM) only transfers the signal which is used by the Driver Information Module (DIM).

The following applies from model year 2005-

The signal of the engine coolant level sensor can be read using VIDA (Volvo scan tool).

The engine control module (ECM) cannot diagnose the engine coolant level sensor.

TEMPERATURE SENSOR, INTAKE (TURBOCHARGED ENGINES ONLY, 2002-2004)

Fig. 107: Identifying Temperature Sensor - Intake (Turbocharged Engines Only, 2002-2004)
Courtesy of VOLVO CARS CORPORATION

On naturally aspirated engines, the intake air temperature sensor is integrated in the mass air flow (MAF) sensor. On model year 2002 turbocharged engines, the temperature sensor is a stand-alone component. On turbocharged engines from model year 2003, the temperature sensor is integrated in the intake air pressure sensor.

The temperature sensor detects the temperature of the intake air after the charge air cooler (CAC). This data is used by the engine control module (ECM) to calculate the boost pressure control (turbocharger (TC) and to calculate the injection period. The control module also controls certain diagnostic functions using the signal from the temperature sensor.

The sensor, which is an NTC resistor, is grounded in the control module and supplied with power (signal) from the control module.

The resistance in the sensor changes according to the temperature of the intake air. This provides the control module with a signal of between 0-5 V. The lower the temperature the higher the voltage (high resistance). A high temperature results in low voltage (low resistance).

The temperature sensor is between the air cleaner (ACL) housing and the intake manifold (does not apply to turbocharged engines 2003-). The temperature sensor on turbocharged engines 2003- is integrated in the intake air pressure sensor.

The engine control module (ECM) can diagnose the temperature sensor. The sensor signal can be read using VIDA (Volvo scan tool).

FUEL PRESSURE SENSOR / FUEL TEMPERATURE SENSOR (ONLY VEHICLES WITH DEMAND CONTROLLED FUEL PUMPS)

Fig. 108: Fuel Pressure Sensor And Fuel Temperature Sensor
Courtesy of VOLVO CARS CORPORATION

The fuel pressure sensor is combined and consisted of both the fuel pressure sensor and the fuel temperature sensor. The sensor detects the fuel pressure (the absolute pressure) and the temperature of the fuel in the fuel rail.

Fuel pressure sensor

The pressure sensor is a Piezo resistive type resistor, the resistance of which changes with the pressure. Depending on the pressure in the fuel rail, an analog signal of 0-5 V is transmitted. Low pressure results in low voltage, high pressure in high voltage.

The engine control module (ECM) then uses this signal to adjust the pressure in the fuel rail using the fuel pump control module. Also, see **FUEL PRESSURE REGULATION (ONLY VEHICLES WITH DEMAND CONTROLLED FUEL PUMPS)**.

The pressure sensor is supplied with 5 V and grounded in the engine control module (ECM). The pressure sensor transmits a signal indicating the fuel pressure to the engine control module (ECM) on a separate cable.

The engine control module (ECM) can diagnose the fuel pressure sensor. Its signals (pressure and temperature) can be read using VIDA (Volvo scan tool).

NOTE: The absolute pressure is displayed when using VIDA parameter readout to read off the fuel pressure. If there is no pressure at the fuel rail, the atmospheric pressure will be displayed.

HINT: The relative pressure (absolute pressure minus atmospheric pressure) is displayed when reading off the fuel pressure via a manometer connected to the fuel rail.

Fuel temperature sensor

The temperature sensor is an NTC sensor. The sensor is supplied with voltage (signal) from and grounded in the engine control module (ECM).

The resistance in the sensor changes according to the temperature of the fuel. This provides the engine control module (ECM) with a signal of between 0-5 V. Low temperature results in high voltage (high resistance). High temperature results in low voltage (low resistance).

The engine control module (ECM) uses the signal to calculate the volume of the fuel.

The fuel pressure sensor is on the left-hand end of the fuel rail.

OIL LEVEL SENSOR (2004-, CERTAIN MARKETS AND MODELS ONLY)

Fig. 109: Identifying Oil Level Sensor
Courtesy of VOLVO CARS CORPORATION

The oil level sensor provides the engine control module (ECM) with information about the quality and temperature of the engine oil and the oil level in the oil trough. Which of these functions is used by the sensor varies between different car models.

All three functions are combined in one unit with a sensor section and an electronics section. There are no moving parts in the sensor.

The sensor consists of:

- a terminal with three pins

- integrated electronics
- 2 capacitive gauge elements
- a PTC resistor.

The oil level sensor is supplied with 5 V by the engine control module (ECM). The oil level sensor generates a PWM signal for the engine control module (ECM). Also, see **OIL LEVEL MONITORING (2004-, CERTAIN MARKETS AND MODELS ONLY)**.

The engine control module (ECM) can diagnose the functions of the oil level sensor. Also, see **OIL LEVEL SENSOR, DIAGNOSTICS** .

The pulse-width modulated (PWM) signal from the oil level sensor can be read using parameter readout.

MAIN RELAY (SYSTEM RELAY)

Fig. 110: Identifying Main Relay
Courtesy of VOLVO CARS CORPORATION

The function of the main relay (system relay) is to supply certain components with voltage.

The relay is mechanical and has a closing function. In the rest position the circuit in the relay is open.

The main relay terminals (#30 and #86) are supplied with voltage by the battery. When the ignition key has been turned and the Engine Control Module (ECM) is powered, the terminal (#85) on the main relay is grounded by the Engine Control Module (ECM).

When the terminal (#85) is grounded, the relay is activated and a number of components are powered via the relay terminal (#87).

The engine control module (ECM) can diagnose the main relay.

The main relay is in the relay/fusebox in the engine compartment.

AIR CONDITIONING (A/C) RELAY

Fig. 111: Air Conditioning Relay
Courtesy of VOLVO CARS CORPORATION

The air conditioning (A/C) relay supplies the A/C compressor with voltage. The relay is controlled by the engine control module (ECM) based on information from different signals:

- the climate control module (CCM) (via the control area network (CAN))
- the engine coolant temperature
- the position of the accelerator pedal (AP)
- the pressure in the system.

The Engine Control Module (ECM) can temporarily disengage the A/C compressor during wide open throttle (WOT) acceleration.

The relay is mechanical. It has a closing / breaking function and is supplied with power from the system relay.

In the rest position the circuit in the relay is open.

The system relay supplies the coil and the relay with power. The relay activates when the coil is grounded in the engine control module (ECM), the circuit closes and the A/C compressor is supplied with power via the relay voltage output.

The relay coil is grounded (signal) when the engine control module (ECM) receives a signal via the Controller area network (CAN) from the climate control module (CCM) to activate the relay and start the compressor.

FUEL PUMP (FP) RELAY, (2002-2004)

Fig. 112: Air Conditioning Relay
Courtesy of VOLVO CARS CORPORATION

The following applies for model year 2002-2004

The fuel pump (FP) relay supplies the fuel pump with power. The relay also cuts the power to the pump when the ignition is switched off or if the engine stops. In cars with demand controlled fuel pumps, the above function applies to the fuel pump control module. The central electronic module (CEM) also cuts the power to the relay if the supplemental restraint module (SRS) transmits a message indicating that an airbag has deployed.

The central electronic module (CEM) activates and deactivates the relay when requested by the engine control module (ECM) (via the Controller area network (CAN)).

When the ignition is switched on, the engine control module (ECM) sends a signal to the central electronic module (CEM) via the controller area network (CAN) to run the fuel pump (FP) for one seconds. This is so that the pressure increases in the fuel system, shortening the start time.

When the flywheel in the engine rotates (generating a signal from the engine speed (RPM) sensor), the engine control module (ECM) will transmit a request to the central electronic module (ECM) via the controller area network (CAN) to start the fuel pump. In the event of the engine stopping, the Engine Control Module (ECM) cancels the "activated fuel pump" signal. The central electronic module (CEM) then switches off the fuel pump.

There is a directly connected cable between the engine control module (ECM) and the central electronic module (CEM). In the event of a fault in the controller area network (CAN), this cable is used for the "activated fuel pump" signal.

INJECTORS

Fig. 113: Identifying Fuel Injector
Courtesy of VOLVO CARS CORPORATION

The function of the injectors is to spray fuel into the cylinders in the correct spray patterns. This happens sequentially.

The injectors are in the intake manifold.

It is essential that the injectors are correctly installed with no air leakage around them. Fuel leakage from the top of an injector when it is not activated may lead to starting and driving problems.

The engine control module (ECM) controls the injectors using a pulse width modulation (PWM) signal.

The injectors for each cylinder have different terminals in the engine control module (ECM), depending on whether the engine has 5 or 6 cylinders.

The engine control module (ECM) can diagnose the injectors. The injectors can be activated using VIDA (Volvo scan tool).

EVAPORATIVE EMISSION SYSTEM (EVAP) VALVE

Fig. 114: Evaporative Emission System Valve
Courtesy of VOLVO CARS CORPORATION

The evaporative emission system (EVAP) valve is used to open/close the connection between the EVAP canister and the intake manifold. The valve controls the flow of hydro-carbons (fuel vapor) from the EVAP canister to the engine intake manifold using the vacuum in the intake manifold. This ensures that hydro-carbons stored in the EVAP canister are used in the engine combustion process.

The valve is an electro-magnetic valve which is powered from the system relay. When the valve needs to be opened, it is grounded internally in the engine control module (ECM). The evaporative emission system (EVAP) valve is closed when in the standby position (open-circuit).

When the control module requests that the EVAP canister should be emptied (the hydrocarbons stored in the canister should be released into the engine), the control module deploys the evaporative emission system (EVAP) valve by grounding it. The valve is grounded using a pulse width modulation (PWM) signal, allowing the control module to govern the extent to which the valve opens and adapting the emptying of the canister according to how full it is, engine speed (RPM) and load etc.

The engine control module (ECM) can diagnose the evaporative emission system (EVAP) valve. The valve can be activated using VIDA (Volvo scan tool).

The evaporative emission system (EVAP) valve is close to the intake manifold.

CAMSHAFT RESET VALVE (CONTINUOUS VARIABLE VALVE TIMING (CVVT))

Fig. 115: Camshaft Reset Valve
Courtesy of VOLVO CARS CORPORATION

The camshaft reset valve controls the oil flow to the CVVT unit (camshaft pulley).

The valve consists of an electro-magnetic valve with a spring-loaded piston. There are slits in the piston which channel the engine lubricating oil to the CVVT unit by moving the piston in the reset valve. The continuous variable valve timing (CVVT) unit turns the camshaft (the cam timing changes). The direction in which the camshaft turns depends on the chamber in the CVVT unit which is supplied with oil (pressure). Also, see **CAMSHAFT CONTROL (CVVT)**.

The system relay supplies the reset valve with voltage. The valve is grounded (control stage) in the engine control module (ECM). When the valve is grounded using a pulse width modulation (PWM) signal, the oil flow in the valve can be controlled to the different chambers in the continuous variable valve timing (CVVT) unit at

variable rates. This allows the cam timing to be changed precisely and steplessly.

The engine control module (ECM) can diagnose the camshaft reset valve.

The valve is on the cylinder head above the camshaft with camshaft control.

TURBOCHARGER (TC) CONTROL VALVE

Fig. 116: Identifying Turbocharger Control Valve
Courtesy of VOLVO CARS CORPORATION

The turbocharger (TC) control valve is used to open/close the connection between the intake manifold and the pressure servo for the turbocharger (TC). The valve controls the pressure servo which affects the boost pressure control (BPC) valve and therefore the boost pressure. Also, see **TURBOCHARGER (TC) CONTROL SYSTEM**.

The valve is an electro-magnetic valve which is powered from the system relay. When the valve needs to be opened, it is grounded internally in the engine control module (ECM). The valve can be controlled steplessly by grounding the valve using a pulse width modulation (PWM) signal.

The valve is closed when in the standby position (open-circuit).

The turbocharger control valve can be diagnosed and can be activated using VIDA (Volvo scan tool).

The turbocharger (TC) control valve is on a hose between the intake manifold and the pressure servo for the turbocharger.

IGNITION COILS

Fig. 117: Identifying Ignition Coils
Courtesy of VOLVO CARS CORPORATION

The ignition coils supply the spark plugs with high voltage to produce sparks. The engine control module (ECM) controls the ignition coils so that sparks are generated at the correct time.

Each ignition coil has its own integrated power stage.

The ignition coils are in the sparkplug wells above each spark plug.

The ignition coils for each cylinder have different terminals in the engine control module (ECM), depending on whether the engine has 5 or 6 cylinders.

The engine control module (ECM) can diagnose the ignition coils.

EMISSIONS WARNING LAMP

Fig. 118: Emissions Warning Lamp
Courtesy of VOLVO CARS CORPORATION

The emissions warning lamp in the Driver Information Module (DIM) has a warning symbol. This warning symbol varies depending on the market and model year. The warning symbols are:

- "Engine symbol" (not USA, model year 2001-)
- "CHECK ENGINE" (MIL - Malfunction Indicator Lamp, USA only).
- "Lambda symbol" (not USA, model year 1999-2000).

The warning symbol lights when the ignition key is turned to position II and goes out when the engine is started if the engine management system does not detect any faults.

The warning lamp is directly connected to the engine control module (ECM).

The warning lamp will light if there is a fault in one of the parameters in the engine management system. The warning lamp will also light in response to a request transmitted via the Control area network (CAN) if there is a fault in one of the following systems which affects emissions:

- transmission control module (TCM)
- brake control module (BCM).

LEAK DIAGNOSTICS, IMPROVED VERSION (2002-)

Fig. 119: Fuel Tank System Leak Overview
Courtesy of VOLVO CARS CORPORATION

All gases that evaporate from fuel in the fuel tank must be led to and stored in the evaporative emission system (EVAP) canister so that they can be directed into the engine for combustion. In order to detect leakages which

cause evaporation of gases into the air, the fuel tank system is diagnosed for leakage. The fuel tank system consists of:

- fuel tank
- the EVAP canister purge valve (1)
- EVAP canister (2)
- leak diagnostic unit (3)
- air cleaner (ACL) (4)
- Roll-over valve (5)
- Float Limit Vent Valve (6)
- fuel filler pipe (7)
- all lines between the above components.

The fuel tank system has a leak diagnostic unit to diagnose any leakage. The leak diagnostic unit pressurizes the fuel tank system when the conditions for leak diagnostics are met.

The control module can detect faults in the function of the leak diagnostic unit and leakage that is 0.5 mm or greater. Minor leak; leakage greater than 0.5 mm but less than 1.0 mm. Major leak; leakage greater than 1.0 mm.

The leak diagnostic unit consists of a pump and a valve that controls the air flow in the unit. The Engine control module (ECM) checks for leakage in the fuel tank system by measuring the relationship between reached pressure and flow from the leak diagnostic pump during pressurization.

If a certain pressure is not reached with a predetermined supplied flow (with known mass), the Engine control module (ECM) interprets this as a leak from the fuel tank system.

Leak diagnostics starts in normal operation when specific conditions are met, see below. The diagnostics can also be started on command using VIDA when some of these conditions are ignored.

Conditions for diagnosis

The diagnosis begins when all the following conditions are met.

Note: When diagnostics are started on command using VIDA, certain different conditions apply.

- No diagnostic trouble codes (DTCs) for EVAP valve or atmospheric pressure sensor may be stored.
- The engine is switched off until the engine coolant temperature (ECT) has fallen to a few degrees above the outside temperature, then engine running for at least 10 minutes
- Ignition off
- Vehicle speed 0 km/h.
- Engine coolant temperature (ECT) 4-35°C.
- Maximum altitude of 2500 meters above sea level
- Outside temperature 4-35 °C.

- Fuel volume in the tank between 0-85 %. The engine control module (ECM) ignores these parameters if a diagnostic trouble code (DTC) is stored for the fuel level sensor and the fuel volume cannot be determined.
- Battery voltage between 11-15 V. The voltage must be stable.
- EVAP canister purge valve closed
- Low volume in the canister.
- Fuel tank filler cap locked. Tip. Locking occurs when the vehicle speed exceeds approximately 20 km/h.

Diagnostic phases

The diagnostic is divided into the following phases and is carried out in sequence when all conditions for the diagnostic have been met.

- reference phase
- function test
- checking the fuel tank system

Reference phase

Before the leak diagnostic begins, the control module runs a reference phase for leakage. During the reference phases for leakage that is 0.5 mm, the pump in the leak diagnostic unit pumps ambient air through a 0.5 mm hole and back out to the ambient air. At the same time, the pump in the leak diagnostic unit is monitored and the reference values stored for later use to determine whether the tank system is leaking or not.

If a reference value for the pump is outside its unexpectedly high or low, or deviates too much, diagnostics is cancelled and a DTC is stored.

Function test

After the reference phase, the valve in the leak diagnostic unit is activated and controls the air flow to the fuel tank to pressurize the fuel tank system. This change of air flow will cause the load the pump to fall briefly before the pressure builds up in the fuel tank system. If the load does not change within permitted parameters within a permitted time, diagnostics is cancelled and a DTC is stored.

Checking the tank system, major leak (leak greater than 1.0 mm)

Diagnostics are carried out every time conditions for diagnostics are met.

The leak diagnostic unit pressurizes the fuel tank system and checks for leaks by monitoring the pressure the fuel tank system. The pressure is a calculated pressure, calculated using the measured pump power consumption. If the pressure stabilizes and/or does not exceed 1500 Pa within 450 seconds, this is interpreted as a leak from the fuel tank system. Diagnostics are cancelled and a DTC for major leak is stored.

Checking the fuel tank system, minor leak (leakage greater than 0.5 mm but less than 1.0 mm)

The diagnostic for minor leaks is run every other time that the conditions for the diagnostic are met. Otherwise

diagnostics stop after checking for major leaks.

The leak diagnostic unit continues to pressurize the fuel tank system. The Engine control module (ECM) checks for leakage in the fuel tank system by measuring the relationship between reached pressure and flow from the leak diagnostic pump during pressurization. In a sealed system the relationship between these must be linear. Any deviations from the linear relationship are calculated and used to determine how well sealed the tank system is.

A diagnostic trouble code (DTC) is stored if a minor leak is detected within 15 minutes.

OVERVIEW

OVERVIEW

The engine control module (ECM) checks itself and all input and output signals.

FOUR DIFFERENT CONDITIONS FOR DIAGNOSTICS

Trip

When all diagnostic functions have been gone through.

Drive cycle

Begins 15 seconds after the engine starts and finishes when the engine is switched off.

Warm-up cycle

Begins when the engine starts and engine coolant temperature (ECT) is below 40°C (104°F) and finishes when the engine temperature is above 84°C (183.2°F).

Time

Some diagnostics are carried out a set amount of time after a particular occurrence (for example when vehicle speed is above 23 km/h (14.3 mph)).

EMISSIONS RELATED DIAGNOSTIC FUNCTIONS

The engine control module (ECM) checks that the emissions related functions are working. These systems are checked by an ongoing diagnostic function. The diagnostic function checks that the relevant components and the actual function in the system are working. It is called a trip when all diagnostic functions have been gone through. Trip time may vary depending on driving style, but normally it takes approximately 25 minutes fir mixed driving.

DIAGNOSTIC TROUBLE CODE (DTC) MEMORY

When the engine control module (ECM) detects a fault, the diagnostic trouble code (DTC) is stored with the qualifier and status in the unit DTC memory. For certain types of diagnostic trouble codes (DTCs) the missing

signal is replaced with a substitute value so that the system can continue to operate.

If the fault disappears, the diagnostic trouble code (DTC) will be present for a longer time in the diagnostic trouble code (DTC) memory although the status of the code will have changed.

MALFUNCTION INDICATOR LAMP (MIL) ACTIVATION

Emissions related diagnostic trouble codes (DTC) are stored even when it is lit. A counter counts down to determine when the malfunction indicator lamp (MIL) should be lit. The conditions for lighting the malfunction indicator lamp (MIL) vary depending on the diagnostic trouble code (DTC) that is stored.

Faults that have been diagnosed in the automatic transmission may affect emissions and the automatic transmission may request the activation of the malfunction indicator lamp (MIL).

LEAK DIAGNOSTICS, ORIGINAL VERSION (-2004)

Fig. 120: Fuel Tank System Overview
Courtesy of VOLVO CARS CORPORATION

All gases that evaporate from fuel in the fuel tank must be led to and stored in the evaporative emission system canister so that they can be directed into the engine for combustion. In order to detect leakages that cause gas to evaporate into the air, the fuel tank system is diagnosed for leakage. The fuel tank system consists of fuel tank,, fuel filler pipe (7), EVAP canister (2), EVAP valve (1), air cleaner (4), leak diagnostic unit (3) and all cables between these components. The fuel tank system has a leak diagnostic unit that makes it possible to diagnose

any leaks. The unit pressurizes the fuel tank system when the ignition is switched off if the conditions for leak diagnostics are met. The control module can detect faults in the function of the diagnostic unit and leakage that is 0.5 mm (minor leak) or greater (major leak, fuel filler cap missing).

The leak diagnostic unit consists of a pump and a valve that controls the air flow in the unit. The fuel tank system tests for leaks by measuring the power consumption of the pump. The power consumption of the pump corresponds to a certain pressure in the fuel tank system. During diagnosis, the rate at which the pressure can build up is checked, taking into account the quantity of fuel in the tank. The quicker the pressurization the better the fuel tank system is sealed.

Conditions for diagnosis

The diagnosis begins when all the following conditions are met:

- There must be no diagnostic trouble code (DTC) stored for the following components or functions:
  - the power stage for the pump in the leak diagnostic unit
  - the power stage for the valve in the leak diagnostic unit
  - the power stage for the EVAP canister purge valve
  - the EVAP canister purge valve.
- Engine off for at least 5 hours (context), engine running for at least 20 minutes (context)
- Ignition off
- Vehicle speed 0 km/h
- Engine coolant temperature (ECT) +4 °C or higher
- Maximum altitude of 2500 meters above sea level
- Outside temperature between +4 and +35 °C
- Stable signal from the fuel level sensor
- Fuel volume in the tank between 15-85 %
- Battery voltage between 11.0-14.5 V. The voltage must be stable
- EVAP canister purge valve closed
- Low volume in the canister.

Diagnostic phases

The diagnostic is divided into the following phases and is carried out in sequence when all conditions for the diagnostic have been met.

- Reference phase 1
- Function test
- Leak diagnostic.

Reference phase and function test

Fig. 121: Fault Free Fuel Tank System Diagram
Courtesy of VOLVO CARS CORPORATION

(the illustration is a diagram of a fault free fuel tank system) Before the actual leak diagnostic begins, the control module enters a reference phase for leakage and checks the components in the system.

Reference phase 1 and reference phase 2

During the reference phases (1-2) for leakage that is 0.5 mm, the pump in the leak diagnostic unit pumps ambient air through a 0.5 mm hole and back out to the ambient air. At the same time, the power consumption of the pump is measured and stored in the control module (A). The stored value for the power consumption of the pump corresponds to a leakage of 0.5 mm.

Function test

If the value for the power consumption of the pump is too high or low during reference phase1 (1-2), or if the value varies too much during reference phase 1 (1-2), the diagnostic is cancelled and starts again the next time the conditions for the diagnostic are met. Diagnostic trouble code (DTC) ECM-431D, faulty signal, is stored if the diagnostic is cancelled 10 times due to excessive variation in the power consumption of the pump.

After the reference phase, the valve (2) in the leak diagnostic unit is activated and controls the air flow to the fuel tank to pressurize the fuel tank system. This change of air flow will cause the power consumption of the pump to fall briefly before the pressure builds up in the fuel tank system (3). Diagnostic trouble code (DTC) ECM-431D, signal missing, is stored if the value for the power consumption of the pump drops too quickly, too

slowly or not at all.

Leak diagnostic

Fig. 122: Fault Free Fuel Tank System Diagram (Major Leak)
Courtesy of VOLVO CARS CORPORATION

(the illustration is a diagram of a fault free fuel tank system). As long as diagnostic trouble code (DTC) ECM-431D is not stored, the leak diagnostic will be carried out after the reference phase and the function test.

Major leak

(leaks >1.0 mm) The diagnostic for "major leaks" is carried out every other time when the diagnostic conditions are met. The leak diagnostic unit pressurizes the fuel tank system, measures the power consumption of the pump (4) and compares this with a calculated desired value (B). If the measured value does not reach the calculated desired value within a certain amount of time (this time is determined by the fuel level in the tank), the function of the leak diagnostic unit is rechecked by running reference phase 2 again to check that low power consumption has not led to changes in the components. Diagnostic trouble code ECM-400C, major leak, is generated if the power consumption of the pump is OK during reference phase 2.

Diagnostic trouble code (DTC) ECM-4338 (fuel tank filler cap missing) will also be stored and the driver will receive a text message in the Driver Information Module (DIM) when a major leak is detected by the Engine Control Module (ECM).

Minor leak

Fig. 123: Fault Free Fuel Tank System Diagram (Minor Leak)
Courtesy of VOLVO CARS CORPORATION

(leaks >0.5 mm <1.0 mm). The diagnostic for "minor leaks" is carried out every 14th time when the diagnostic conditions are met. The diagnostic for major leaks is always run before the diagnostic for minor leaks. The leak diagnostic unit continues to pressurize the fuel tank system (5). If the measured value (6) is the same or less than the value stored in the reference phase (A) after a certain amount of time (determined by the fuel level in the tank), reference phase 2 (7) is run to ensure that the lower power consumption (6) is not the result of changes in components. If the measured power consumption during the second reference phase (7) is lower than that measured during pressurization (6), the control module interprets this as meaning that the fuel tank system is sealed. Diagnostic trouble code ECM-400C, minor leak, is generated if the measured power consumption from the second reference phase (7) is the same or higher than that measured during pressurization (6).

LEAK DIAGNOSTICS, ORIGINAL VERSION (2005-)

Fig. 124: Fuel Tank System Leak Overview
Courtesy of VOLVO CARS CORPORATION

All gases that evaporate from fuel in the fuel tank must be led to and stored in the evaporative emission system (EVAP) canister so that they can be directed into the engine for combustion. In order to detect leakages which cause evaporation of gases into the air, the fuel tank system is diagnosed for leakage. The fuel tank system consists of:

- fuel tank
- the EVAP canister purge valve (1)
- EVAP canister (2)
- leak diagnostic unit (3)
- air cleaner (ACL) (4)
- Roll-over valve (5)
- Float Limit Vent Valve (6)
- fuel filler pipe (7)
- all lines between the above components.

The fuel tank system has a leak diagnostic unit to diagnose any leakage. The leak diagnostic unit pressurizes the fuel tank system when the ignition is off, if the conditions for diagnosis have been met. The control module can detect faults in the function of the leak diagnostic unit and leakage that is 0.5 mm or greater. Minor leak; leakage greater than 0.5 mm but less than 1.0 mm. Major leak; leakage greater than 1.0 mm.

The leak diagnostic unit consists of a pump and a valve that controls the air flow in the unit. The fuel tank system tests for leaks by measuring the power consumption of the pump. The power consumption of the pump corresponds to a certain pressure in the fuel tank system. During diagnosis, the rate at which the pressure can build up is checked, taking into account the quantity of fuel in the tank. The quicker the pressurization the better the fuel tank system is sealed.

Conditions for diagnosis

The diagnosis begins when all the following conditions are met:

- There must be no diagnostic trouble code (DTC) stored for the following components or functions:
  - the power stage for the pump in the leak diagnostic unit
  - the power stage for the valve in the leak diagnostic unit
  - the power stage for the EVAP canister purge valve
  - the evaporative emission system (EVAP) valve
  - the engine coolant temperature (ECT) sensor
  - speed signal.
- The engine is switched off until the engine coolant temperature (ECT) has fallen to a few degrees above the outside temperature, then engine running for at least 10 minutes
- Ignition off
- Vehicle speed 0 km/h
- Engine coolant temperature (ECT) -5 °C or higher
- Maximum altitude of 2500 meters above sea level.
- Outside temperature between -5 and +35 °C
- Fuel volume in the tank less than 85 %. The engine control module (ECM) ignores these parameters if a diagnostic trouble code (DTC) is stored for the fuel level sensor and the fuel volume cannot be determined
- Battery voltage between 11.0-14.5 V. The voltage must be stable
- EVAP canister purge valve closed
- Low volume in the canister.

Fuel tank filler cap check

The exception from the above conditions is when the car has been refuelled. The engine control module (ECM) starts a check of the fuel tank filler cap after refuelling. This check is a simplified version of the leak diagnostic unit for major leaks. The fuel tank filler cap control is run while the vehicle is being driven. This allows the control module to check that the cap has been reinstalled. A diagnostic trouble code (DTC) is stored in the engine control module (ECM) and a text message is displayed in the driver information module (DIM) if the cap is missing.

Diagnostic phases

The diagnostic is divided into the following phases and is carried out in sequence when all conditions for the

diagnostic have been met.

- Reference phase
- Function test
- Leak diagnostics

Reference phase (1-2)

Fig. 125: Fault Free Fuel Tank System Diagram
Courtesy of VOLVO CARS CORPORATION

The illustration is a diagram of a fault free fuel tank system.

Before the leak diagnostic begins, the control module runs a reference phase for leakage. During the reference phase (1-2) for leakage that is 0.5 mm, the pump in the leak diagnostic unit pumps ambient air through a 0.5 mm hole and back out to the ambient air. At the same time, the power consumption (A) of the pump is measured and stored in the control module. The stored value (A) for the power consumption of the pump corresponds to a leakage of 0.5 mm. This value is then used by the engine control module (ECM) to determine the leak status of the fuel tank system.

Function test (1-3)

If the value for the power consumption of the pump is too high or low during the reference phase (1-2), or if the

value varies too much during the reference phase (1-2), the diagnostic is cancelled and starts again the next time the conditions for the diagnostic are met. A diagnostic trouble code (DTC) is stored if the diagnostic is cancelled several time in a row because the power consumption of the pump is varying excessively.

After the reference phase, the valve (2) in the leak diagnostic unit is activated and controls the air flow to the fuel tank to pressurize the fuel tank system. This change of air flow will cause the power consumption of the pump to fall briefly before the pressure builds up in the fuel tank system (3). A diagnostic trouble code is stored if the value for the power consumption of the pump drops too quickly, slowly or not at all.

Leak diagnostic, major leak (leakage greater than 1.0 mm)

Fig. 126: Fault Free Fuel Tank System Diagram (Major Leak)
Courtesy of VOLVO CARS CORPORATION

The diagnostic for "major leaks" is carried out each time when the conditions for the diagnostic are met. The leak diagnostic unit pressurizes the fuel tank system, measures the power consumption of the pump (4) and compares this with a calculated desired value (B). A diagnostic trouble code (DTC) for a major leak is stored if the measured value does not reach the calculated desired value within a certain time (the time is determined by atmospheric pressure and the fuel level in the tank).

Leak diagnostic, minor leak (leakage greater than 0.5 mm but less than 1.0 mm)

The diagnostic for minor leaks is run every other time that the conditions for the diagnostic are met. The diagnostic for major leaks is always run before the diagnostic for minor leaks. The leak diagnostic unit

continues to pressurize the fuel tank system (5-6). After a certain amount of time (the time varies depending on the fuel level in the tank), the engine control module (ECM) checks that the fuel tank system for leaks. This is determined based on:

- time
- the measured reference current consumption of the pump (A)
- the measured power consumption of the pump when the assessment is made
- the shape and character of the current curve during pressurization.

A diagnostic trouble code (DTC) is stored if a minor leak is detected.

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the engine control module (ECM). When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module. If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

The engine control module (ECM) is positioned in the cool box in the engine compartment.

The engine control module (ECM) contains a unique code for each car for the immobilizer. The central electronic module (CEM) checks this code at engine start up. The engine will not start if the central electronic module (CEM) detects an incorrect code for the immobilizer. This means that the engine control module (ECM) cannot be switched from car to car.

The engine control module (ECM) must first be "unlocked" using a unique PIN for each car before it can be programmed with a code for the immobilizer. When the engine control module (ECM) has approved the PIN, the code for the immobilizer can be programmed.

The PIN and the code for the immobilizer are obtained from the Volvo central database and sent out with the software package when software for downloading has been ordered.

All new engine control modules (ECM) have the same PIN which is preprogrammed by the control module supplier. After the engine control module (ECM) has been programmed successfully the original PIN for the car will be programmed in the engine control module (ECM) memory and replace the preprogrammed PIN code.

FUNCTION

CAMSHAFT CONTROL (CVVT)

Fig. 127: Camshaft Control
Courtesy of VOLVO CARS CORPORATION

When the camshaft is set at the factory, it is aligned with the position of the crankshaft. The position of the camshaft in relation to the crankshaft is designated the camshaft 0 position. During camshaft control (CVVT) the camshaft 0 position is offset. The value of the 0 position offset is called the cam timing. The cam timing is 0° if the camshaft is not being controlled.

By controlling the cam timing (the camshaft is deployed from its 0 position) the performance of the engine is increased, the idle speed quality is improved and the emissions are reduced.

In order to detect the cam timing, the engine control module (ECM) uses the signals from the engine speed (RPM) sensor (the position of the crankshaft) and from the camshaft position (CMP) sensor (the position of the camshaft). By comparing these two signals, the control module is able to determine the cam timing (the number of degrees the camshaft is from its 0 position).

There are diagnostic for this function, see **CAMSHAFT DIAGNOSTICS (CVVT)** .

Camshaft cam timing

Fig. 128: Camshaft Cam Timing
Courtesy of VOLVO CARS CORPORATION

The camshaft (A) is divided into four flanks per revolution of the camshaft (flanks 1-4). The angle between flanks 1-2 = 103°, flanks 2-3 = 90°, flanks 3-4 = 90° and flanks 4-1 = 77°. The angle between the flanks is different, allowing the control module to determine which flank it is detecting and therefore determine which combustion cycle the cylinders are in,

The crankshaft has four reference positions, one for each camshaft flank. The camshaft turns at half the speed of the crankshaft. This means that two reference positions are detected for each turn of the crankshaft. Therefore two engine revolutions are required to detect all flanks on the camshaft. For example (may vary between different engine variants): flank 1 at 0°, flank 2 at 206°, flank 3 at 386° and flank 4 at 576° (flanks 3 and 4 are detected during the second engine revolution).

The reference positions of the crankshaft coincide exactly with each camshaft flank if the camshaft cam timing is 0°. If the cam timing deviates from 0°, i. e. the flanks deviate from the reference positions of the crankshaft,

the control module calculates the number of crankshaft degrees by which the flank is deviating.

The control module detects the reference positions for the camshaft flanks using the signal from the engine speed (RPM) sensor.

Example:

If camshaft flank 1 is detected at 10° from the crankshaft reference position for flank 1 (0° +10°), the cam timing is 10°. If the cam timing is the same (10°), flank 2 is detected at 216° (206° + 10°), flank 3 at 396° (386° + 10°), and flank 4 at 586° (576° + 10°). The cam timing can be positive (+) or negative (-) depending on whether the flank is detected before or after the different reference positions for the crankshaft.

The engine control module (ECM) controls the camshaft reset valve smoothly in order to regulate the camshaft cam timing. The valve controls the flow of engine oil to the continuous variable valve timing (CVVT) unit which is affected by the oil pressure that builds up.

see **CAMSHAFT RESET VALVE (CONTINUOUS VARIABLE VALVE TIMING (CVVT))**.

Control

Fig. 129: CVVT Control
Courtesy of VOLVO CARS CORPORATION

Control takes place as follows when deploying the camshaft:

1. Oil is forced from the engine lubricating system to the intake port on the reset valve
2. The engine control module (ECM) grounds the valve, the position of the piston in the valve changes and the oil is guided to the continuous variable valve timing (CVVT) unit chamber (A1) via the duct (A2) in the camshaft
3. The continuous variable valve timing (CVVT) unit hub is pressed backwards by the oil pressure. The continuous variable valve timing (CVVT) unit then rotates the hub and the carriers are joined by twisted splines
4. The oil flows to the engine oil pan via the outer ducts on the hub and the reset valve's return hose.

Control takes place as follows when returning the camshaft:

1. Oil is forced from the engine lubricating system to the intake port on the reset valve
2. The engine control module (ECM) breaks the ground connection for the valve. The piston in the valve is then pressed back by a spring. The oil flows to the continuous variable valve timing (CVVT) unit chamber (B1) via a duct (B2) in the camshaft
3. The hub of the continuous variable valve timing (CVVT) unit is forced forward by the oil pressure that is created. The continuous variable valve timing (CVVT) unit will rotate back to the non-deployed position
4. The oil flows to the engine oil pan via the center duct on the hub and the reset valve's return duct.

The above takes place very quickly. The engine control module (ECM) controls the deployment and return of the reset valve continually at high frequency. This results in rapid and exact control. The extent of camshaft control (the change of cam timing) varies depending on the engine variant and the model year.

"Wide Range" concept

Fig. 130: Wide Range Concept
Courtesy of VOLVO CARS CORPORATION

Ignition timing

The combustion of the fuel film on the cylinder walls is improved by retarding the ignition.

Retarded ignition reduces the efficiency of the engine and the heat energy which is generated is released with the exhaust gases. This is used to heat the three-way catalytic converters (TWC).

Exhaust camshaft (turbocharged engines)

By opening the exhaust valve late, combustion takes place over a relatively long period. The film of fuel on the cylinder walls combusts, reducing the exhaust emissions.

Intake camshaft

By opening/closing the intake valve late:

- so that there is little or no overlap, a predetermined pressure difference is maintained between the intake manifold and the combustion chamber/cylinder. The lower pressure in the cylinder ensures that all the injected fuel reaches the cylinder. This allows the Engine Control Module (ECM) to calculate and control the fuel quantity required in the combustion phase in advance

- maintains a high and stable pressure in the intake manifold (due to the upwards movement of the piston). Stable high pressure means that the vaporization of the fuel which has condensed on the walls of the intake manifold can be predicted.

Double continuous variable valve timing (CVVT)

CVVT on both the intake camshaft and the exhaust camshaft means that the valve overlap can be changed to a greater degree than on engines where only one of the camshafts is controlled. Valve overlap is the extent to which the intake and exhaust valves (on the same cylinder) are open at the same time.

The advantages of continuous variable valve timing (CVVT) are used in different operating conditions:

- *during cold starting and during the warm-up phases* when the intake camshaft and exhaust camshaft are set late. This reduces the emissions
- *during idle and when the engine is at operating temperature* when the exhaust camshaft is set to early and the intake camshaft is set to late. This results in small valve overlap, reducing exhaust gas recirculation (EGR) and ensuring stable idling
- *at part load* when both the exhaust and intake camshaft are set to relatively late, with greater valve overlap. Greater valve overlap results in internal exhaust gas recirculation (EGR) which reduces the release of nitrous oxide. This also limits the incoming fuel/air mixture to the cylinder. As a result, the throttle does not need to reduce the supply of air, thereby reducing "pump losses" and lowering the fuel consumption. At higher engine speeds (RPM), the camshafts are set for a smaller valve overlap. The exhaust camshaft is set earlier, the intake camshaft later. This provides an optimum fuel/air mixture to the cylinder. Reduces internal exhaust gas recirculation (EGR).

TURBOCHARGER (TC) CONTROL SYSTEM

Fig. 131: Turbocharger Control System
Courtesy of VOLVO CARS CORPORATION

HINT: The above illustration is for a 6 cylinder engine. However the principle is the same for 5 cylinder engines.

The boost pressure in the intake manifold is controlled by the boost pressure control (BPC) valves, whose pressure regulators (1) are affected by the pressure from the turbocharger (TC) (2).

The Engine Control Module (ECM) receives information about the actual throttle position via the throttle position sensor (TP) for the throttle unit (3), engine load, knocking etc. This affects the boost pressure that is permitted. The boost pressure is measured by the boost pressure sensor.

The control module controls the control pressure using the turbocharger (TC) control valve (4), see **TURBOCHARGER (TC) CONTROL VALVE**), which controls the pressure to the boost pressure control (BPC) valves so that the control is adapted to the required pressure.

The pressure regulators in the boost pressure control (BPC) valves are affected when the pressure rises. When the boost pressure has increased to the maximum permissible value, the boost pressure control (BPC) valves open. Some of the exhaust gases pass the turbine in the turbocharger (TC), limiting the boost pressure.

Turbocharger (TC) control is governed continually by the engine control module (ECM).

When a higher boost pressure is permitted, the control module opens the turbocharger (TC) control valve further. Some of the boost pressure which affects the pressure regulators for the boost pressure control (BPC) valves is released back into the turbocharger (TC) intake. This lowers the control pressure, the boost pressure control (BPC) valves open later and the boost pressure increases.

Because the control module calculates the boost pressure using the signal from the boost pressure sensor and the intake temperature sensor, there is automatic compensation of boost pressure control when driving at altitude and at different temperatures. As a result engine power will not be noticeably affected by the air density or temperature.

The engine control module (ECM) can diagnose the turbocharger (TC) control function.

THROTTLE CONTROL

Fig. 132: Identifying Throttle Control
Courtesy of VOLVO CARS CORPORATION

To ensure that the correct throttle angle is reached, the engine control module (ECM) controls the throttle shutter in the throttle unit (6/120), mainly using the signal from:

- accelerator pedal (AP) position sensor (7/51)
- clutch pedal sensor (7/123)
- stop lamp switch (3/9)
- the throttle position (TP) sensor on the electronic throttle unit (6/120)
- brake control module (BCM) (4/16), signal for the brake pedal sensor.

Additional signals and parameters are used to ensure optimum throttle control. For example there is

compensation for the load from the air conditioning (A/C) compressor, load from the transmission depending on the gear selected (automatic), engine temperature etc. In cars with Four-C (Continuously Controlled Chassis Concept), the throttle characteristic changes depending on the driving mode selected.

The position of the throttle is measured by two potentiometers, in the throttle position (TP) sensor, which are on the throttle unit. These are connected, so that potentiometer 1 produces a higher voltage as the throttle angle increases, while potentiometer 2 does the opposite.

In a combustion engine, the difference between the minimum and maximum airflow is considerable. The smaller air flows need more thorough regulation, so the potentiometer signal from potentiometer 1 is amplified approximately 4 times in the engine control module (ECM) before it reaches the Analog/Digital converter in the engine control module (ECM). This means that there are three, two real and one fictitious, input signals available to the engine control module (ECM). These signals are used to determine the position of the throttle and to deploy the damper motor to the correct position. In general the amplified signal is primarily used for small throttle angles (small air flows), which are desirable when a high degree of accuracy is required, for idle air trim for example.

Because the signal is amplified, it reaches its maximum value as early as approximately a quarter of maximum deployment.

The engine control module (ECM) first uses the signal from potentiometer 1 to measure the throttle opening. The signal from potentiometer 2 is mainly used to check that potentiometer 1 is functioning correctly. The engine control module (ECM) then uses the signal to calculate a throttle angle (actual value). This is the actual throttle angle. The value for the actual throttle angle is used by those functions in the engine control module (ECM) which depend on this information so that the throttle can be correctly regulated.

There is an adaptation (learning) in the engine control module (ECM) so that the control module can calculate how the damper motor needs to be controlled. See "Adaptation of the throttle unit" below. This adaptation is carried out during manufacture of the car, when the engine control module (ECM) deploys the throttle disc to the different positions and reads off and registers the actual values from the potentiometers.

The throttle angle is regulated so that the actual angle (actual value) is the same as the angle calculated by the engine control module (ECM) (desired value). The engine control module (ECM) also uses the values that were stored during adaptation of the throttle angle, and the actual signals from the potentiometers.

The damper motor is controlled by a power stage integrated in the engine control module (ECM) using a pulse width modulation (PWM) signal. The torsion from the opening and return springs in the throttle unit is also used. If there is a fault in the engine control module (ECM) so that the throttle unit cannot be operated or supplied with power, the springs in the throttle unit will turn the throttle disc to the limp home position (return position). This return position gives a throttle angle large enough to allow the car to be driven to a workshop, although with considerably reduced drivability.

Throttle angle

The throttle angle is usually gauged by potentiometer 1. For small angles the amplified signal is used to obtain a clearer signal. The engine control module (ECM) also monitors the throttle unit signals from the potentiometers to check that they are plausible, that they are within the minimum and maximum limits and that the signals correspond to the same throttle angle. If there is a difference in the signals, a fictitious throttle signal is

calculated from the load signal, the engine speed (RPM) and the prevailing conditions, particularly pressure and temperature.

The potentiometer whose signal is closest to the calculated throttle angle will then be assumed to be correct. The other potentiometer is then classified as not functioning and a diagnostic trouble code (DTC) is stored. The system then constantly monitors the throttle angle of the remaining potentiometer in comparison to the calculated throttle angle. If there is a difference between these values, the engine control module (ECM) will not rely on any of the throttle unit potentiometers. The power stage in the throttle unit is then disengaged, and the throttle switches to limp home mode (return position).

Adaptation of the throttle unit

Normally the engine control module (ECM) adapts the throttle unit during manufacture of the car. There are a number of other occasions when the throttle unit must be adapted. A new adaptation is obviously required if the throttle unit or the engine control module (ECM) is replaced, but also if the software in the engine control module (ECM) is replaced. This is because the adaptation values are stored in the EEPROM memory in the control module, at a predetermined location in the memory for each software. These storage locations may vary between different software, in which case a new adaptation will be required. The final reason for adaptation is that the values for the throttle unit may have changed during its service life. Therefore there is a routine which begins adaptation of the throttle unit if the car is left with the engine off and the throttle on for 30 seconds (and other basic conditions for adaptation of the throttle unit are met). A new adaptation is then carried out. If the "new" values are different from the "old" values, the new values are used. Adaptation usually takes place automatically when the engine control module (ECM) detects that the adaptation has not been run or that the values from a previous adaptation are outside certain tolerances. However a number of basic conditions must be met to ensure that the adaptation is carried out correctly:

Basic conditions for adaptation of the throttle unit:

- ignition on / engine off
- battery voltage above 10 V
- accelerator pedal (AP) released (unaffected)
- the car must be stationary (no speed signal)
- engine coolant temperature (ECT) between 5 and 100 °C
- intake air temperature (IAT) above 5 °C.

During adaptation, the engine control module (ECM) checks that the values obtained are within reasonable limits. This helps to determine whether the throttle unit is functioning correctly or not. When the adaptation has been carried out, all relevant values are stored in the EEPROM memory in the control module so that they can be retrieved if the power supply is broken. This means that if the battery is replaced for example, a new adaptation is not necessary.

FUEL TRIM

Fig. 133: Fuel Trim
Courtesy of VOLVO CARS CORPORATION

Overview

Fuel trim reduces exhaust emissions. Fuel trim reduces nitrous oxide (NO_x), carbon monoxide (CO) and hydrocarbon (HC) emissions.

Theoretically, if the correct amount of oxygen is added during combustion, fuel can be converted to water (H_2O) and carbon dioxide (CO_2). Emissions would then be completely safe.

In practice considerable amounts of hydro-carbons (HC) and varying amounts of carbon monoxide (CO) and carbon dioxide (CO_2) remain.

Fig. 134: Fuel Trim
Courtesy of VOLVO CARS CORPORATION

Due to the high temperature and pressure, nitrous oxides such as NO and NO_2 are also formed. The common designation for these gases is nitrous oxides NO_x .

Fig. 135: Converting Exhaust To H2O And CO2
Courtesy of VOLVO CARS CORPORATION

By speeding up the reaction between the remaining reactive components using a catalytic converter, these can be converted to water (H_2 O), carbon dioxide (CO_2) and nitrogen (N_2).

However this can only happen if the balance of hydro-carbons (HC), carbon monoxide (CO), oxygen (O_2) and nitrous oxides (NO_x) is exactly right in the exhaust. This happens when the fuel air mixture before combustion is 14.7 kg of air per kg of fuel. The Lambda value is then said to be one, (lambda=1).

Fig. 136: ECM Signal Input And Output For Exhaust
Courtesy of VOLVO CARS CORPORATION

A base program in the engine control module (ECM) calculates the injection period based on data about load, i. e. the measured air mass and engine speed (RPM). The calculated injection time (from the base program) is then modified by a circuit (short-term fuel trim). The signal from the heated oxygen sensor (HO2S) is used to finely

adjust the injection period so that lambda=1 is reached. The short-term fuel trim is also a circuit that finely adjusts the injection period so that the fuel air mixture is optimized (lambda=1). The control module also used the signals from the front and rear heated oxygen sensors (HO2S) to correct the front heated oxygen sensor (HO2S) (offset adjustment) and thereby the injection period. This gives a higher degree of accuracy during fuel trim. Fuel trim is a rapid process which may take place several times a second. Adjustment of the calculated injection period calculated in the base program is limited.

The fuel trim can be read off using VIDA (Volvo scan tool).

Adaptive functions

Fig. 137: Adaptive Function Charts
Courtesy of VOLVO CARS CORPORATION

Certain factors, such as deviations in tolerance for certain components such as the mass air flow (MAF) sensor and injectors, intake air leakage, fuel pressure etc, will affect the composition of the fuel air mixture. To compensate for this, the engine control module (ECM) has adaptive (self learning) functions. When the engine is new, the short-term fuel trim is assumed to vary cyclically around a nominal center line (A) 1.00 with, for example, a ± 5% change in the injection period when fuel trim is active.

If there is air leakage for example, the short-term fuel trim will quickly be offset to a new position (B) and will then work for example between 1.10 (+10%) and 1.20 (+20%), although still at an amplitude of 5%, but with an offset in relation to the original center line (A). The injection period has then been increased to compensate the increase in the amount of air.

The adaptive functions will correct the change, so that the short-term fuel trim will work around the new center line (B) where it will again have its full range of control available.

Put simply, fuel trim is a measurement of the difference (C) between the original short-term fuel trim center line (A) and the new center line (B).

Fig. 138: Adaptive Function Sections
Courtesy of VOLVO CARS CORPORATION

The adaptive functions consist of three sections and correspond to the different operating ranges of the engine; load (D) and engine speed (E):

- Additive adaptation (1) is when the engine is idling. This is how the control module adjusts the CO content at idle speed. Long-term fuel trim, idling can be read off using VIDA
- Multiplicative adaptation, lower part load (2), carried out in the lower part load range. Lower part load range is reached when driving at low load. Long-term fuel trim, lower part load can be read off using VIDA
- Multiplicative adaptation, upper part load (3). Carried out in the upper part load range. The upper part load range is reached when driving under high load and at high engine speed (RPM). Long-term fuel trim, upper part load can be read off using VIDA (Volvo scan tool).

The adaptive adjustments of the injection period are stored continuously in the control module. This means that under different operating conditions the fuel air mixture is obtained before the heated oxygen sensor (HO2S) is warm enough to function.

A diagnostic trouble code (DTC) will be stored in the control module if any adaptation value is too high or too low. For further information, also, see **HEATED OXYGEN SENSOR (HO2S) DIAGNOSTIC** .

KNOCK CONTROL

Fig. 139: Identifying Knock Control
Courtesy of VOLVO CARS CORPORATION

Knocking occurs in the combustion chamber when the fuel and air mixture self ignites. This can occur either before or after the spark plug has produced an ignition spark. In both cases the gas in two or more places ignites in the combustion chamber.

This results in an extremely fast combustion process with flames from several directions. When these flames collide, the pressure in the cylinder increases rapidly and there is a mechanical knocking sound.

If any of the cylinders knock there is a specific type of vibration in the cylinder block. These vibrations are transferred to the knock sensors (KS) which are screwed into place in the cylinder block. The resultant mechanical stress in the piezo electrical material in the knock sensors generates a voltage. The engine control module (ECM) can then determine which cylinder is knocking with the help of the camshaft position (CMP) sensor and the engine speed (RPM) sensor.

The knock sensors (KS) also interpret a proportion of normal engine sound. The control module is able to recognize the vibrations which correspond to knocking by filtering, amplifying and using software to evaluate the signal.

If the knock sensors (KS) detect knocking in the engine over a certain threshold value, the ignition timing is first retarded and then the fuel / air mixture is enriched to eliminate knocking.

IGNITION CONTROL

Fig. 140: Ignition Control Signal Input And Output
Courtesy of VOLVO CARS CORPORATION

The following components are used for ignition control:

- engine speed (RPM) sensor (7/25)
- camshaft position (CMP) sensor (7/172-7/173)
- mass air flow (MAF) sensor (7/17)
- engine coolant temperature (ECT) sensor (7/16)
- throttle position (TP) sensor on the electronic throttle unit (6/120)
- knock sensor (KS) (7/23-7/24)
- transmission control module (TCM) (4/28)
- spark plugs with ignition coils (20/3-20/8)
- brake control module (BCM) (4/16).

The engine control module (ECM) calculates the optimum ignition advance based on the software and information from the sensors. The engine control module (ECM) cuts the current to the ignition coil mounted on the cylinder to be ignited and produces a spark.

During the starting phase the engine control module (ECM) produces a fixed ignition setting. When the engine starts and the car is driven the engine control module (ECM) calculates the optimum ignition setting according to the engine speed (RPM), load, temperature etc.

The engine control module (ECM) analyses the signal from the knock sensors (KS) when the engine reaches operating temperature. If any of the cylinders knock, the ignition is retarded for that specific cylinder until the knocking ceases.

The ignition then advanced to the normal position or until the knock recurs.

Before the transmission control module (TCM) changes gear, it sometimes transmits a torque limiting request to the engine control module (ECM). The engine control module (ECM) then retards the ignition momentarily to reduce the torque, resulting in smoother gear changes and reducing the load on the transmission. There are different ignition retardation levels depending on the signals from the transmission control module (TCM). The return signal from the engine control module (ECM) to the transmission control module (TCM) confirms that the signal reached the engine control module (ECM). The Brake Control Module (BCM) transmits information to the engine control module (ECM) about deviations in the drive line. The signal is used to stop the diagnosis., see **MISFIRE DIAGNOSTICS** .

CRUISE CONTROL

Fig. 141: Cruise Control
Courtesy of VOLVO CARS CORPORATION

The cruise control function is an example of distributed functionality.

The following components are used when driving using cruise control:

- engine control module (ECM)
- electronic throttle unit
- brake control module (BCM)
- accelerator pedal (AP) position sensor
- clutch pedal sensor
- brake pedal sensor
- control unit cruise control
- steering wheel module (SWM)
- central electronic module (CEM)
- transmission control module (TCM)
- driver information module (DIM).

To activate cruise control the function must be switched on using the "CRUISE" button. A lamp lights up in the

driver information module (DIM).

The driver activates the function by pressing the SET+ or SET- button. A message is then transmitted via the low speed side of the Controller area network (CAN) to the central electronic module (CEM) which then transmits the message on via the high speed side of the Controller area network (CAN) to the engine control module (ECM).

The engine control module (ECM) controls the throttle angle so that a constant speed is maintained using the vehicle speed signal from the Brake Control Module (BCM). The transmission control module (TCM) also receives a message indicating that cruise control is active via the Controller area network (CAN), so that the transmission follows certain shifting patterns when the cruise control is active.

If the accelerator pedal (AP) is depressed the speed increases as normal and then resumes to the stored value when the driver releases the accelerator pedal (AP) again.

The engine control module (ECM) continually stores the speed. If the cruise control is disengaged, if for example the driver presses the brake pedal, the previous stored speed can be used by pressing the "RESUME" button.

Cruise control cannot be activated at speeds below 35 km/h.

Cruise control is disengaged:

- when the driver presses the clutch pedal or brake pedal
- when the driver presses the "CRUISE" button on the steering wheel
- when the driver depresses the "0" button on the steering wheel
- if the "P" or "N" positions are transmitted on the controller area network (CAN) (applies to automatic transmissions)
- if the speed deviates too much from the set value
- when certain diagnostic trouble codes (DTCs) are stored which do not allow continued activation

FUEL PRESSURE REGULATION (ONLY VEHICLES WITH DEMAND CONTROLLED FUEL PUMPS)

Fig. 142: Fuel Pressure Regulation
Courtesy of VOLVO CARS CORPORATION

General

Fuel pressure regulation for demand controlled fuel pumps (DECOS - DEmand COntrolled fuel Supply) means that the fuel pressure is controlled steplessly by varying the output of the fuel pump. The design of the system allows a greater maximum pressure (approximately 6.5 bar) in the fuel pump. This pressure is used in extreme situations, such as heavy engine load for example.

The following components are used for fuel pressure regulation:

- engine control module (ECM)
- the fuel pump control module
- a fuel pressure sensor with a fuel temperature sensor
- a fuel pump (FP) with a by-pass valve.

The time taken for the engine start procedure can be reduced by rapidly increasing the pressure in the fuel rail when the engine control module (ECM) receives a signal about the position of the ignition switch from the central electronic module (CEM).

The engine control module (ECM) is better able to calculate the injection period because the signal from the fuel pressure sensor gives information about the fuel pressure. This particular improves the cold starting

characteristics of the engine.

The advantages of varying the output of the fuel pump so that it is not always at full power are:

- the total power consumption of the fuel pump (FP) is reduced, reducing the load on the power supply system
- the service life of the fuel pump (FP) is increased
- fuel pump noise is reduced.

Control

The engine control module (ECM) calculates the desired fuel pressure. A signal is then transmitted to the fuel pump control module indicating the desired fuel pressure. Serial communication between the engine control module (ECM) and the fuel pump control module is used to carry the signal. The fuel pump control module then operates the fuel pump unit to obtain the desired pressure using a pulse width modulation voltage on the ground lead. The fuel pump (FP) can be controlled steplessly by changing the pulse width modulation (PWM) signal. Only that pressure which is required at that specific time will then be released to the fuel rail/injectors. The value of the pulse width modulation (PWM) signal is a measurement of the operational load of the fuel pump (FP) (% duty, 100% = maximum pressure).

The engine control module (ECM) continuously monitors the fuel pressure using the signal from the fuel pressure sensor. This allows the desired fuel pressure to be reached, and if necessary a signal is transmitted to the fuel pump control module requesting that the fuel pressure is adjusted.

By-pass valve

When the injectors are closed because of too high pressure (during engine braking for example) there is a pressure peak. The by-pass valve in the fuel pump (FP) is used to even out the pressure peak. The opening pressure of the valve is approximately 6.5 bar.

The by-pass valve also functions as a non-return valve, ensuring that the fuel pressure in the system is maintained when the engine is switched off.

There is high pressure before the engine is started. This high pressure means that the valve in the by-pass valve opens and the system is "flushed".

Passive safety

For safety reasons, the engine control module (ECM) shuts off the fuel pump (FP) if the supplemental restraint system module (SRS) detects a collision.

OIL LEVEL MONITORING (2004-, CERTAIN MARKETS AND MODELS ONLY)

General

The following components are used for oil monitoring:

- the oil level sensor
- engine control module (ECM)
- driver information module (DIM).

One of the advantage of always monitoring the oil level is that the driver can then be informed, via the driver information module (DIM), if the oil needs topping up.

Oil quality detection

To calculate the quality of the oil, the capacitance of the oil is gauged and then compared with the capacitance of the air. (Capacitance is the ability to store an electrical charge).

The capacitance of the oil and air is measured using both the capacitive gauge elements. The volume of contaminants in the oil increases the capacitance. This provides the electronics integrated in the oil level sensor with an oil quality dependent input signal.

Oil temperature detection

The PTC resistor integrated in the oil level sensor is used to calculate the oil temperature. The resistance of the PTC resistor changes, depending on the oil temperature. The resistance increases as the oil temperature rises. This provides the electronics integrated in the oil level sensor with a temperature dependent input signal.

Oil level detection

The electronics integrated in the sensor calculate the oil level using the obtained values for oil temperature and quality.

Temporary changes in the oil level in the oil trough must be taken into account to correctly calculate the oil level. This happens when cornering and taking hills for example. The engine control module (ECM) makes these calculations using the oil level sensor signal and a number of other parameters. These other parameters include the vehicle speed signal and the load signal.

Oil level sensor signal

The oil level sensor internally calculates the parameters for oil level, quality and temperature. A PWM signal is then generated and transmitted on a cable to the engine control module (ECM).

The PWM signal consists of a pulse train. The first pulse in the pulse train represents the oil temperature. The second pulse represents the oil level. The third pulse represents the oil quality. A change in oil level, quality or oil temperature affects the pulse ratio of the relevant pulse.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 143: Air conditioning (A/C) relay
Courtesy of VOLVO CARS CORPORATION

The Engine Control Module (ECM) controls the following functions:

- injectors
- ignition
- camshafts (CVVT)
- evaporative emission system (EVAP) valve
- turbocharger (TC) control
- throttle angle
- engine cooling fan (FC)
- Air conditioning (A/C) compressor
- fuel pump (only vehicles with demand controlled fuel pumps).

There is a micro-processor in the control module which receives signals from the different sensors in the car. The micro-processor uses a program which interprets the signals from the different sensors and how the components / functions should be controlled.

The control module has several self-learning (adaptive) functions. It continually adapts ongoing calculations to changing circumstances (wear, air leaks, differences between different fuels etc.).

Emissions are kept low through efficient management of the injection period, ignition, evaporative emission system (EVAP) valve and camshafts etc. Faults which affect emissions can be detected by running diagnostics for functions and components.

The control module is in a box in the engine compartment.

The engine control module (ECM) communicates with other control modules using controller area network (CAN) communication.

The engine control module (ECM) checks activations, input and output signals and functions using an integrated diagnostic system. A diagnostic trouble code (DTC) is stored if, after validation, the control module

detects a fault. In certain cases the faulty signal is replaced with a substitute value or certain functions are limited.

Substitute values can be set for e. g.:

- engine coolant temperature (ECT)
- mass air flow
- throttle position
- atmospheric pressure
- etc.

Mathematical calculations and signals from certain components are used to calculate the substitute values. Other substitute values are fixed, predefined values in the control module.

The substitute value allows the car to be driven and for the emissions to be kept at a reasonable level even though vital functions / components are faults.

Functions which are limited may be for example:

- turbocharger (TC) control
- Camshaft control (CVVT)
- fuel trim
- throttle angle
- etc.

A function is limited so that the system still functions, to protect components or for safety reasons (for example the throttle angle).

Any diagnostic trouble codes (DTCs) are stored in the control module memory. The data can be read off using VIDA (Volvo scan tool).

SIGNALS

The table below summarizes the input signals to and output signals from the Engine Control Module (ECM). The signal types are divided into directly connected signals, serial communication and controller area network (CAN) communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: • Ignition switch (3/1) • Stop lamp switch (3/9) • Clutch pedal sensor (7/123) • Air conditioning (A/C) pressure sensor (7/8)	**Directly connected:** • Main relay (system relay) (2/32) • Fuel pump (FP) relay (2/23) • Air conditioning (A/C) relay (2/22) • Electronic throttle unit (6/120)

• Front heated oxygen sensor (HO2S) (7/15) • Rear heated oxygen sensor (HO2S) (7/82) • Engine coolant temperature (ECT) sensor (7/16) • Mass air flow (MAF) sensor (7/17) • Manifold absolute pressure (MAP) sensor, intake (7/81) (certain turbocharged engines only) • Manifold absolute pressure (MAP) sensor, with integrated intake air temperature (IAT) sensor, intake (7/81) (certain turbocharged engines only) • Leak diagnostic unit (6/67), (certain markets only) • Electronic throttle unit (6/120) • Outside temperature sensor (7/105) • Camshaft position (CMP) sensor (7/172) • Camshaft position (CMP) sensor (7/173) • Engine speed (RPM) sensor (7/25) • Accelerator pedal (AP) position sensor (7/51) • Engine coolant level sensor (7/73) • Knock sensor (KS) (7/23-7/24) • Manifold absolute pressure (MAP) sensor, intake (7/77) (not turbocharged engines 2003-2004) • Oil level sensor (7/35) (certain markets and models only) • Fuel pressure sensor with integrated fuel temperature sensor (7/156) (vehicles with demand controlled fuel pumps only).	• Engine cooling fan (FC) control module (4/71) • Engine cooling fan (FC) control module box (6/44) (turbocharger (TC) only and certain markets) • Front heated oxygen sensor (HO2S), preheating (7/103) • Rear heated oxygen sensor (HO2S), preheating (7/104) • Injectors (8/6-8/11) • Leak diagnostic unit (6/67), (certain markets only) • Evaporative emission system (EVAP) valve (8/18) • Camshaft reset valve (CVVT) (8/19) (certain engines only) • Camshaft reset valve (CVVT) (8/81) (certain engines only) • Turbocharger (TC) control valve (8/28) • Ignition coils (20/3-20/8) • Driver information module (DIM) (5/1), emissions warning lamp • Fuel pump control module (6/33) (only vehicles with demand controlled fuel pumps) • Central electronic module (CEM) (4/56).
Via Controller Area Network (CAN) communication: • Transmission Control Module (TCM) (4/28) (only cars with automatic transmissions) • Brake control module (BCM) (4/16) • Central electronic module (CEM) (4/56) • Suspension module (SUM) (4/84) (vehicle with Four-C (Continuously Controlled Chassis Concept) only). Via central electronic module (CEM) (4/56):	**Via Controller Area Network (CAN) communication:** • Transmission Control Module (TCM) (4/28) (only cars with automatic transmissions) • Brake control module (BCM) (4/16) • Central electronic module (CEM) (4/56) • Differential electronic module (DEM) (4/82) (AWD only) • Suspension module (SUM) (4/84) (vehicle with Four-C (Continuously Controlled Chassis Concept) only).

• Climate Control Module (CCM) (3/112) • Data link connector (DLC) (17/13) • Driver information module (DIM) (5/1) • Steering wheel module (SWM) (3/130).	Via central electronic module (CEM) (4/56): • Climate Control Module (CCM) (3/112) • Data link connector (DLC) (17/13) • Driver information module (DIM) (5/1) • Steering wheel module (SWM) (3/130).

BRAKE CONTROL SYSTEM (2003-2012)

CALIBRATING DSTC (DYNAMIC STABILITY AND TRACTION CONTROL)

For active yaw control to operate after a repair, brake control modules (BCM) with DSTC (dynamic stability and traction control) must be calibrated. This means that the brake control module (BCM) adjusts the signals from the unique sensors in the DSTC (dynamic stability and traction control) system.

When replacing:

- The brake control module (BCM), data for the steering wheel angle sensor module (SAS), brake pressure sensor and the DSTC sensor module must be calibrated
- The brake pressure sensor, data for the brake pressure sensor must be calibrated
- DSTC sensor module, the data for the sensor module must be calibrated.

Generally calibration must be carried out after repair to a component which affects the position of the steering wheel in relation to the position of the front wheels.

Calibrating is carried out according to VIDA vehicle communication.

DESIGN

CONTROL MODULE AND ABS HYDRAULIC MODULATOR

The brake control module (BCM) is mounted on the hydraulic modulator in the engine compartment.

The control module is supplied with power via two fuses and connected to ground by two ground terminals.

There are diagnostics for the valve coils.

The brake control module (BCM) is available in two different versions.

Fig. 146: Control Module And ABS Hydraulic Modulator
Courtesy of VOLVO CARS CORPORATION

ABS control module

The control module contains two different micro-processors which receive signals from different sensors in the system. The micro-processors operate in parallel and use a program to compute the necessary ABS and electronic brake force distribution functions. The ABS control module has eight valve coils for the hydraulic valves, four outlet valves and four inlet valves.

The control module has a connector for connection to the car wiring.

Fig. 147: ABS Control Module
Courtesy of VOLVO CARS CORPORATION

Control module for STC (stability and traction control), DSTC (dynamic stability and traction control), and TRACS (traction control system)

The control module for STC/DSTC/TRACS has twelve valve coils for the hydraulic valves; four are outlet valve coils, four are inlet valve coils and four are used for stability and traction control.

When replacing brake control modules (BCM) with DSTC, the control module must be calibrated according to the instructions in VIDA vehicle communication or by a special test drive.

Fig. 148: Control Module For STC, DSTC And TRACS
Courtesy of VOLVO CARS CORPORATION

ABS hydraulic modulator

The hydraulic modulator is available in three versions; ABS, STC (stability and traction control) and DSTC (dynamic stability and traction control)/TRACS (traction control system). The ABS hydraulic modulator is located in the engine compartment.

The ABS hydraulic modulator consists of hydraulic valves, check valves and a pump motor. The pump motor builds up the brake pressure required during ABS or stability control.

There are diagnostics for the pump motor.

STC/DSTC SWITCH

Fig. 149: Identifying Climate Control Module (CCM)
Courtesy of VOLVO CARS CORPORATION

The switch for STC/DSTC is positioned next to the other buttons on the lower section of the climate control module (CCM). The stability and traction control functions can be switched on and off manually (this applies only to the stability function from model year 2003 inclusive). When the ignition is switched on all functions are engaged. The switches have a green LED indicator which display the ON-position. When STC/DSTC is switched on or off, this is confirmed by a message in the driver information module (DIM). If the STC-/DSTC function is disabled, the other functions work normally.

NOTE: The figure shows switch for car equipped with STC.

WARNING LAMPS

Fig. 150: Warning Lamps
Courtesy of VOLVO CARS CORPORATION

The brake system uses four warning lamps positioned in the combined instrument panel.

ABS warning lamp

The ABS warning lamp indicates an ABS system fault.

Brake warning lamp

The brake warning lamp indicates:

- faults in the electronic brake force distribution (EBD) function
- that the brake fluid level is too low.

Traction control warning lamp (only cars with STC/DSTC) model year 1999-2002

The traction control warning lamp is on continuously when:

- STC/DSTC is deactivated because a diagnostic trouble code (DTC) is stored
- The STC/DSTC system has been manually switched off
- the brake disc temperature is too high.

The traction control warning lamp flashes when:

- a drive wheel starts to spin during acceleration. The control module is activated to regain traction
- the lateral stability limit is exceeded (the car oversteers or understeers) during active yaw control.

Traction control warning lamp (only cars with STC/DSTC) model year 2003-

The traction control warning lamp is lit continuously when the road surface is slippery.

The traction control warning lamp flashes when:

- there is a risk of a loss of traction
- a drive wheel starts to spin during acceleration. The control module is activated to regain traction
- the lateral stability limit is exceeded (the car oversteers or understeers) during active yaw control.
- the limit for the anti-roll function is exceed and active yaw control is activated to regain stability.

General warning lamp model year 1999-2002

The general warning lamp (red/yellow) lights only for those faults in the brake control system which disable emergency brake assistance.

General warning lamp model year 2003-

- STC/DSTC is deactivated because a diagnostic trouble code (DTC) is stored
- The brake disc temperature is too high.

Text display model year 2003-

The stability function has been manually disabled using the STC/DSTC switch.

WHEEL SENSORS

Fig. 151: Identifying Wheel Sensors
Courtesy of VOLVO CARS CORPORATION

There are four wheel sensors, one at each wheel. The wheel sensors supply the control module with information about the rotation speed, acceleration and retardation of each wheel. By recording the pulses, the control module can calculate the wheel speed.

The wheel sensors are active sensors. When the pulse wheel rotates, the sensor generates a pulsed current (quadratic wave) where the strength of the current depends on the position of the pulse wheel. The signals from the coils in the wheel sensors are then affected by a magnetic resistance element, which generates a current which changes between 7mA and 14mA, and whose frequency increases with speed.

On the front wheels, the pulse wheel is pressed onto the outer constant velocity joint and the wheel sensors are

located radially in the shaft housing relative to the pulse wheel. On the rear wheels, the pulse wheel is pressed onto the hub and the wheel sensors are located axially relative to the pulse wheel. Both the front and rear pulse wheels have 48 teeth. In the event of a fault in any of the wheel sensors the following systems will be disengaged or will not engage:

- ABS
- TRACS
- STC
- DSTC.

Electronic brake force distribution (EBD) is available if one wheel sensor is faulty. Electronic brake force distribution (EBD) is disengaged if there is a fault in more than one wheel sensor simultaneously.

The control module calculates the vehicle speed using the signals from the wheel sensors. There are diagnostics for the wheel sensors.

BRAKE LAMP SWITCH

Fig. 152: Identifying Brake (Stop) Light Switch
Courtesy of VOLVO CARS CORPORATION

The brake lamp switch is a single pole switch positioned at the brake pedal lever. The brake lamp switch self-

adjusts during installation.

The brake control module (BCM) receives information about the status of the brake lamp switch via the engine control module (ECM). The brake lamp switch signal is used by the brake control module (BCM) to diagnose faults in the pedal position sensor.

The brake lamp switch is supplied with power from the battery. When the switch is closed, the signal is grounded through the engine control module (ECM). The engine control module (ECM) then transmits a signal on the Control area network (CAN) indicating that the brake lamp switch has been activated.

There are diagnostics for the brake lamp switch.

SENSOR MODULE (ONLY DSTC)

Fig. 153: Sensor Module
Courtesy of VOLVO CARS CORPORATION

The sensor module is installed under the right-hand front seat and contains two to four sensors, depending on which of the three versions is installed. The information from the sensor module is used for stability calculations in the brake control module (BCM). The sensor module for 2 wheel drive cars contains a yaw angle sensor which measures the yaw angle speed in °/s, and a lateral acceleration sensor which measures lateral acceleration in m/s^2 . The sensor module all-wheel drive (AWD) also contains a yaw angle sensor and lateral acceleration sensor as well as an acceleration sensor which measures longitudinal acceleration in m/s^2 .

The XC90 also has a tilt sensor in the sensor module. The tilt sensor gauges the tilt rate in °/s. The sensor is installed using a new bracket, turned 90°.

The sensor module communicates with the brake control module (BCM) via an internal control area network (CAN).

The supply voltage to the sensor is 12V and is connected to ground.

There are diagnostics for the sensor module.

When replacing the sensor module, the brake control module (BCM) must be calibrated according to the information in VIDA vehicle communication or manually according to the test drive.

ACTIVE SERVO UNIT, PEDAL PRESSURE SENSOR (DSTC ONLY)

Fig. 154: Active Power Brake Booster, Pedal Pressure Sensor
Courtesy of VOLVO CARS CORPORATION

The servo unit is positioned on the bulkhead in the engine compartment. It consists of a vacuum cylinder (1), pedal position sensor (2), pressure build-up valve (3) and pedal pressure sensor (4). The pressure build-up valve and the pedal pressure sensor (activation unit) have a common connector which cannot be replaced.

The pedal pressure sensor is positioned in the servo unit and provides the brake control module (BCM) with information about brake activity. If the driver presses the brake pedal during stability control, the control module will take account of this.

The active servo unit is controlled by the brake control module (BCM) and builds up an initial brake pressure. This is so to allow braking during active yaw control. An active brake pressure is obtained within 0.1 seconds. This occurs without the driver needing to brake. The pressure build-up valve opens and allows atmospheric pressure to enter the rear chamber in the servo unit. The brake pressure sensors (5) continuously monitor the brake pressure. The pulse width controlled pressure build-up valve in the servo unit maintains the brake pressure at approximately 10 bar during stability control.

PEDAL POSITION SENSOR

Fig. 155: Identifying Brake Pedal Position Sensor
Courtesy of VOLVO CARS CORPORATION

The pedal position sensor is mounted on the servo unit in the engine compartment. The sensor has several functions. It is used to:

- register rapid pedal movements for emergency brake assistance
- shut off the traction control during braking
- to diagnose the function of the brake lamp switch
- it is used by the engine control module (ECM) for cruise control. The signal is transmitted via the control area network (CAN).

The sensor, which responds to the push rod for the pedal, is a sliding potentiometer. 0 mm corresponds to 0 V and 38.5 mm movement corresponds to approximately 95 % of battery voltage (U_{bat}).

BRAKE PRESSURE SENSOR (ONLY DSTC)

Fig. 156: Brake Pressure Sensor
Courtesy of VOLVO CARS CORPORATION

Two brake pressure sensors are positioned on the master cylinder. One sensor is located on the primary circuit and one on the secondary circuit. The information is transmitted via two analogue signals (measurement range 0-5 V) and is used by the brake control module (BCM) to calculate the brake pressure during active yaw control, and when the driver applies the brakes.

The sensors are supplied with voltage via the brake control module (BCM). There are diagnostics for the sensors.

When replacing the brake pressure sensor, the brake control module (BCM) must be calibrated according to the information in VIDA vehicle communication or manually according to the test drive.

DIAGNOSTIC FUNCTIONS

GENERAL INFORMATION

Fig. 157: Brake Control Module
Courtesy of VOLVO CARS CORPORATION

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

If the control module detects a fault, a diagnostic trouble code (DTC) is set. Any fault detected during the last run cycle is defined as permanent. Other faults are defined as intermittent. A run cycle comprises ignition on, the car speed exceeding 10 km/h (20 km/h in XC90 with B8444S engine) and ignition off.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF INPUT AND OUTPUT SIGNALS

This function can be used to continuously read off the status of the control module's input and output signals.

ACTIVATING COMPONENTS

This function can be used to activate components to check that they are working.

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain the following information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N (part of the software).

FUNCTION

ABS FUNCTION

Fig. 158: ABS Function
Courtesy of VOLVO CARS CORPORATION

While driving, the brake control module (BCM) (1) registers the acceleration and deceleration of the wheels. The 4 wheel sensors (3) (one on each wheel) give the brake control module (BCM) information about the rotation speed of the wheels. The brake control module (BCM) calculates the speed of the car using this information and puts it out on the Control area network (CAN). There the signal is accessible for other systems.

During braking, the brake control module (BCM) receives a signal from the stop (brake) lamp switch (2)

indicating braking. The brake control module (BCM) then goes into standby mode for ABS control. The signal from the stop (brake) lamp switch is not required for ABS control, but does give softer control at the beginning of ABS control.

If the brake control module (BCM) detects that there is a risk of wheel lock-up, the ABS hydraulic modulator (4) is affected and the hydraulic pressure for the relevant wheel is adapted so that wheel lock up is avoided.

The pressure in the circuit is controlled so that the maximum possible braking force is transferred to the road surface. This occurs when the wheel rotates with 12-20% slippage on the surface.

ABS is first activated when the speed of the car exceeds approximately 7 km/h, which means that at speeds below approximately 7 km/h the wheels can lock up. This has little practical effect on the function of the system or from the driver's point of view.

ABS control can be divided into three stages:

1. Open position. (Pressure increase). This is the normal condition during braking. The inlet valve is open and the outlet valve is closed. This permits the brake pressure to pass from the master cylinder to the wheel
2. Pressure retention phase. (Constant pressure). If the brake control module (BCM) detects that one of the wheels is rotating too slowly, the brake control module (BCM) will close the inlet valve. This stops the brake pressure to the wheel from increasing, even if the driver increases the pressure on the brake pedal. If the rotation speed of the wheel continues to fall the control moves into the pressure reduction phase
3. Pressure reduction phase. (Pressure release). The inlet valve remains closed. The brake control module (BCM) opens the outlet valve and starts the pump which transfers brake fluid from the wheel, this reduces the brake pressure. When the rotation speed has increased sufficiently the control module closes the exhaust valve, opens the inlet valve and control returns to the open position.

Steps 1, 2 or 3 are repeated until braking finishes or the ABS system stops.

ABS CONTROL

No braking

Fig. 159: ABS Control -- No Braking
Courtesy of VOLVO CARS CORPORATION

When the driver is not braking, the brake system is unaffected (i. e. the master cylinder is in the rest position and the connections between the brake fluid reservoir and the rest of the hydraulic system is open). There is no pressure in the system. In the ABS hydraulic modulator valve block, the hydraulic valves are in their rest position. In other words, the inlet valves are open and the outlet valves closed.

Braking without ABS

Fig. 160: ABS Control -- Braking Without ABS
Courtesy of VOLVO CARS CORPORATION

When the brake pedal is depressed, the movement of the pedal is transmitted via the power brake booster to the master cylinder pistons and the stop (brake) lamp switch trips. When the primary and secondary pistons move forwards in the master cylinder, the openings for the brake fluid reservoir are closed. The hydraulic pressure in the two brake circuits increases and affects the pistons in the brake calipers which press the brake pads against the brake discs.

When the brake pedal is released, the pistons revert to the rest position in the master cylinder. The connection to the brake fluid reservoir opens and the brake system pressure falls. The brake caliper pistons return to their rest positions with the aid of the sealing rings.

Braking with ABS

Fig. 161: ABS Control -- Braking With ABS
Courtesy of VOLVO CARS CORPORATION

When a wheel locks-up under braking, the brake control module (BCM) begins to close the inlet valve for the relevant brake circuit so that the supply of brake fluid from the master cylinder is interrupted. This means that the hydraulic pressure cannot increase irrespective of the pressure in the master cylinder (constant pressure). The hydraulic pump starts at the same time.

If the wheel locks anyway, the outlet valve opens and the brake fluid is allowed back to the accumulators resulting in a reduction in the brake circuit pressure (pressure release). This reduces the hydraulic pressure and braking effect, allowing the wheel to accelerate. The hydraulic pump returns the brake fluid from the accumulators to the master cylinder.

When the acceleration is sufficient, the brake control module (BCM) closes the outlet valve and opens the inlet valve, so that the hydraulic pressure in the circuit increases. During the pressure increase phase the required fluid volume is supplied by the master cylinder and the pump if the accumulators contain brake fluid. As the volume of fluid supplied to the brake circuit is greater than the volume released back into the accumulators from the brake circuits, the accumulators only compensate for the volume peaks on the pump suction side. The pump returns the brake fluid from the low pressure accumulators to the master cylinder or brake circuits depending on the position of the inlet valves.

When the pump operates the brake pedal is raised and lowered (pulses). This is normal and is also a warning to the driver that ABS control is active.

The hydraulic pump is operational for approximately 1 second after the ABS control has finished to ensure that the accumulators are empty.

ELECTRONIC BRAKE FORCE DISTRIBUTION (EBD)

Fig. 162: Electronic Brake Force Distribution
Courtesy of VOLVO CARS CORPORATION

Electronic brake force distribution (EBD) is integrated in the ABS system and controls the braking forces to the rear wheel brakes. Electronic brake force distribution (EBD) replaces the relief valve, which otherwise reduces the pressure in the brake circuit for the rear wheels and prevents premature activation of rear ABS control.

Electronic brake force distribution controls the hydraulic pressure in the brake circuit for the rear wheels the rear wheels slip considerably less than the front wheels under braking. This ensures optimal and stable braking.

The brake control module (BCM) controls the brake pressure by controlling the inlet and outlet valves in the rear wheel brake circuits.

The brake pressure in the rear wheel circuits varies, depending on how much the rear wheels slip in relation to the front wheels. This functions tries to keep the rear wheel slippage 0-2 % lower than front wheel slippage. The function is load sensitive.

Generally, the difference between the rear wheel and front wheel slippage under braking is dependent on how hard the brakes are applied and on the load of the car. Hard braking /light loads cause more slippage, light braking/heavy loads cause less slippage.

Therefore the requirement for brake fluid when the hydraulic pump is not activated during electronic brake

force distribution (EBD) control is less than during stability and traction control. The fluid volume returned from the brake circuits is taken up by the accumulators.

STC (STABILITY AND TRACTION CONTROL) SYSTEM

The STC (stability and traction control) system consists of two functions, stability control and traction control. The stability function is controlled by the engine control module (ECM). The traction control function and TRACS (TRAction Control System) operate in the same way.

STABILITY CONTROL

Stability control occurs when the brake control module (BCM) transmits a signal to the engine control module (ECM) to lower the engine torque if any of the wheels loose traction. Stability control is available between 0 km/h and top speed. For information about traction control.

TRACTION CONTROL

Fig. 163: Identifying Traction Control
Courtesy of VOLVO CARS CORPORATION

Components

1. Separation valve, normally open
2. Electronic shuttle valve, normally closed

3. Hydraulic pump
4. Outlet valve, normally closed
5. Inlet valve, normally open
6. Pressure equalizer
7. By-pass valve
8. Non-return valve.

Traction control is integrated in the steering wheel bracket.

The system is mainly designed to assist with moving off on slippery surfaces at speeds up to approximately 60 km/h. Traction control has only a very limited effect at speeds over 60 km/h.

The traction control function is always engaged when the ignition is switched on. The function can be disengaged (model years 1999-2002 only) using the STC/DSTC switch, which is located on the lower section of the climate control module (CCM).

If the brake control module (BCM) registers, via the front wheel sensors, that one of the driven wheels is spinning faster than the other, the separation valve (1) closes and the hydraulic pump (3) starts so that the brake fluid is pumped to the brake caliper of the slipping wheel. Pressure builds up in the brake circuit and the brakes are applied as much as required so that the drive force is distributed between the driven wheels. The wheel which has the best traction receives the most driven force against the surface. This process is independent of engine output.

On cars with traction control, the brake control module (BCM) continually registers brake usage and calculates the temperatures of the front wheel brake discs. If traction control is engaged and the calculated temperature is too high (approximately 450 °C), traction control cuts out and the wheel spin warning indicator lights (applies to model year 1999-2002). From model year 2003, the general warning lamp (yellow) lights, and a text is displayed in the combined instrument panel. A diagnostic trouble code (DTC) is stored in the brake control module (BCM). Traction control is blocked to prevent the brakes from overheating. The light goes out once the calculated temperature falls below approximately 300 °C and traction control is engaged again. However, the ABS function is always available. Information about the calculated temperature of the brake discs is in the brake control module (BCM) as long as the 30-supply is connected. If the brake system has been used too hard, this may also cause high brake temperatures.

TRACTION CONTROL

No traction control

Fig. 164: Identifying Traction Control -- No Traction Control
Courtesy of VOLVO CARS CORPORATION

When the driven wheels are not spinning the brake system is unaffected (i. e. the master cylinder is in the rest position and the connections between the brake fluid reservoir and the rest of the hydraulic system are open). There is no pressure in the system. In the ABS hydraulic modulator valve block, the hydraulic valves are in their rest position. In other words, the inlet valves and the separation valves are open and the outlet valves closed.

Traction control when one or both driven wheels spin

Fig. 165: Identifying Traction Control -- Traction Control When One Or Both Driven Wheels Spin
Courtesy of VOLVO CARS CORPORATION

If the car moves off and one or both driven wheels are threatening to slip, the brake control module (BCM) detects this by comparing the signals from the wheel sensors with a calculated reference speed. The control module closes one or both separation valves and the hydraulic pump starts. The separation valve blocks the connection between the pump pressure side and the master cylinder primary circuit /secondary circuit. The inlet valve for the non-spinning wheel closes so that the brake is not applied on that wheel. The hydraulic pump draws brake fluid from the brake fluid reservoir via the electronic shuttle valve and increases the pressure until the by-pass valve opens. The hydraulic pressure reaches the spinning wheel and slows down the wheel so that the driven force is distributed between the driven wheels so that the wheel with the best traction receives the most driven force.

As the pump supplies a greater flow than required by traction control, the excess brake fluid is drained off by the by-pass valve for the master cylinder or is drawn directly up by the pump.

If traction control is manually disengaged (model tears 1999-2002) it can be re-engaged using the switch while the wheels are spinning. The function then starts more softly than normal.

The inlet valve closes as soon as the spinning wheel has been slowed down by the brake to a relatively normal speed. Depending on the acceleration of the wheel, the outlet valve opens (brake fluid flows back to the suction side of the pump) so that the pressure in the brake circuit drops or the outlet valve remains closed to maintain the pressure (constant pressure). The outlet valve closes to increase the pressure in the brake circuit, the inlet valve opens and the pressure rises in the brake circuit.

This control brakes the wheel in proportion to optimum slippage until one of the following occurs:

- As friction against the surface becomes greater wheel spin stops
- The process is stopped by the brake control module (BCM) to prevent the brakes from overheating
- Braking occurs
- The function is disengaged using the switch on the climate control module (CCM) (applies to model years 1999-2002)
- The car reaches the speed where traction control ceases.

If the rear wheels lock during traction control (for example the parking brake is applied), the brake control module (BCM) stops traction control to allow ABS to cut-in. The traction control lamp lights (applies to model years 1999-2002).

The separation valve is activated during traction control.

Activating the brakes, which is registered by the brake control module (BCM) via the signal from the stop (brake) lamp switch, enables the traction control to be interrupted and the separation valve to open. The electronic shuttle valve closes, so that the pump is unable to draw brake fluid from the master cylinder. The hydraulic modulator now operates as a normal ABS hydraulic modulator.

A difference in speed between the driven wheels requires traction control. This difference varies with the speed of the car. When the vehicle speed is 0 km/h, a difference in speed of 8 km/h between the driven wheels is required for traction control to function. At a vehicle speed of 20 km/h, a difference of 18 km/h, and at 40 km/h a difference of 25 km/h are required. At higher speeds the differences required between the driven wheel speeds is so great that in practice traction control does not function above 60 km/h.

ACTIVE YAW CONTROL SYSTEM

Fig. 166: Active Yaw Control System
Courtesy of VOLVO CARS CORPORATION

The brake control module (BCM) with DSTC (dynamic stability and traction control) uses continuous information from the different sensors in the system to calculate the positions of the steering wheel and car. The brake control module (BCM) calculates the driving manner of the driver by measuring the steering wheel angle, the engine torque, the speed of the car and brake pressure. The brake control module (BCM) also calculates the behavior of the car by monitoring the steering wheel angle, steering wheel angle speed, yaw rate speed and lateral acceleration. When the differences between the movements of the driver and the behavior of the car exceed a certain point, Active Yaw Control limits the engine torque to maintain lateral stability in all driving conditions. Active Yaw Function also activates the power brake booster and the individual brake control to control the hydraulic modulator separation valves and electronic shuttle valves and the inlet and outlet valves which correct the car in the event of a skid.

ACTIVE YAW CONTROL

Fig. 167: Active Yaw Control
Courtesy of VOLVO CARS CORPORATION

1. Inlet valve, normally open
2. Outlet valve, normally closed
3. Electronic shuttle valve, normally closed
4. Separation valve, normally open
5. Brake pressure sensor
6. Pedal pressure sensor
7. By-pass valve
8. Hydraulic pump
9. Pressure absorber
10. Non-return valve
11. Pressure build-up valve.

During Active Yaw Control, when the car skids, a vacuum valve opens on the power brake booster. The power brake booster then quickly builds up pressure without the driver activating the brake pedal. At the same time the hydraulic pump (8) starts and builds up brake pressure. The hydraulic pump takes over braking after the initial phase. The brake control module (BCM) then activates the valves in the hydraulic modulator and checks the individual wheel brake forces by raising, maintaining or lowering the pressure individually to stabilize the car. The brake pedal moves up and down during activation. If the driver presses the brake pedal during stability

control, the control module, through the pedal pressure sensor (6) in the power brake booster, will take account of the pressure exerted by the driver in the stability control.

Active yaw control oversteer

Fig. 168: Active Yaw Control Oversteer
Courtesy of VOLVO CARS CORPORATION

Oversteer is a very dangerous condition which is difficult for the average driver to control. Oversteer is when the car turns more than the steering wheel has been turned. If not corrected, oversteer can lead to the car spinning uncontrollably.

In the example above the car turns to the right and the car oversteers. To counter this the DSTC system has closed the separation valve, opened the electronic shuttle valve and started the pump. The inlet valve (C1) has been left open, while the other inlet valves are closed. This causes brakes the left front wheel, which causes the wheel to lose grip and reduces oversteer.

Active yaw control understeer

Fig. 169: Active Yaw Control Understeer
Courtesy of VOLVO CARS CORPORATION

Understeer is when the car continues straight forward even though the steering wheel has been turned. Understeer is caused by too much acceleration. When the car understeers the brake control module (BCM) transmits a request for torque reduction to the engine control module (ECM) via the Controller area network (CAN).

In the example above, the steering wheel has been turned to the right, but the car continues straight on. The separation valve closes, the electronic shuttle valve opens and the pump starts. The DSTC system applies the brakes to the right rear wheel by leaving inlet valve C2 open and closing and closing the other inlet valves (C1, C3 and C4). In the event that braking the right rear wheel is not sufficient to get the car back on course, the brake control module (BCM) opens inlet valve C4 and brakes the right front wheel.

Dynamic stability control

Fig. 170: Dynamic Stability Control
Courtesy of VOLVO CARS CORPORATION

When the driver brakes during Active Yaw Control, the brake control module (BCM) releases the active power brake booster and increases the brake pressure for a short time as priority is given to the lateral stability of the car. Included in the calculations are the driver's desired brake pressure and functions for:

- Active yaw control
- ABS
- EBD
- Stability control.

In the event of a hand brake turn, the anti-yaw control function is activated if the speed exceeds approximately 40 km/h. At lower speeds the AYC is decreased successively, and at 20-25 km/h will not be noticeable.

The self diagnostic function, for valves and pump motors, occurs at speeds exceeding 20 km/h after a new drive cycle. The self diagnostic function for the active power brake booster takes place when the speed exceeds 11 km/h. The self diagnostics are carried out at each new drive cycle.

If the driver presses the brake pedal during stability control, the control module, through the pedal pressure sensor in the power brake booster, will take account of the pressure exerted by driver in the stability control.

SOFTWARE DOWNLOADING

New software can be downloaded into the brake control module (BCM). When ordering software, the hardware and the software in the car is compared to the data in the Volvo central database. If the comparison is OK the software is downloaded to the control module. If the comparison between the car and Volvo central database is

not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

SYSTEM OVERVIEW

INTRODUCTION

The Mark 25 brake control system

The Mark 25 brake control system with the brake control module (BCM) is an electronic control system which prevents wheel lock up during braking (ABS). By preventing wheel lock up, steering control is maintained and maximum braking effect is utilized.

The brake control system is equipped with:

- Antilock Braking System
- Electrical Brake force Distribution (EBD) for the rear wheel brakes.

The brake control system, as a factory installed option, can be supplemented with:

- TRACS (TRAction Control System)
- STC (Stability and Traction Control)
- DSTC (Dynamic Stability and Traction Control).

EBD

EBD (Electrical Brake force Distribution) is a function for electronically controlling the brake force on the rear wheels and is integrated with the ABS system. The purpose of the control module for electronic brake force distribution (EBD) control is to control the hydraulic pressure in the brake circuit for the rear wheels if the rear wheels tend to lock under braking. This ensures optimal and stable braking. The EBD function replaces the relief valve used in the Mark IV version to reduce the pressure in the brake circuit for the rear wheels.

TRACS

TRACS is a traction control system which is integrated with the ABS system. TRACS is only available on all-wheel drive (AWD) cars. The traction control system distributes driven power between the wheels so that the wheel with the best road traction receives the greatest amount of driven power. The system is mainly designed to assist with moving off on slippery surfaces at speeds up to approximately 60 km/h. TRACS has only a very limited effect at speeds over 60 km/h. TRACS (traction control system) is always engaged when the ignition is switched on. TRACS (traction control system) is engaged and disengaged using a switch under the climate control module (CCM). From model year 2003 inclusive, the TRACS function cannot be disabled manually.

STC

STC (stability and traction control) consists of two components:

- Traction Control - this function is described above under TRACS. The traction control function is always engaged when the ignition is switched on. The traction control function together with the stability

function is engaged and disengaged using a switch under the climate control module (CCM). From model year 2003 inclusive, the Traction Control function cannot be disabled manually

- Stability Control - stability system which is integrated in the ABS system and stabilizes the car in the event of wheel spin. The brake control module (BCM) transmits a signal to the engine control module (ECM) to reduce engine torque until the slipping wheel(s) has/have stopped spinning. The stability function is always engaged when the ignition is switched on. The stability function together with the traction control function is engaged and disengaged manually using a switch under the climate control module (CCM).

DSTC

DSTC (Dynamic Stability and Traction control) - a dynamic anti-slip system which is integrated in the STC (stability and traction control) system. The DSTC (dynamic stability and traction control) function is engaged when the ignition is switched on but can be disengaged or engaged manually using the switch on the climate control module (CCM).

The DSTC (Dynamic stability and traction control) system consists of the following:

- Traction Control - This function is described above under TRACS
- Stability Control - Described under STC above
- AYC (Active Yaw Control). The system is based upon a number of sensors which sense the driver's steering movements (steering wheel angle) and the directional, both straight and lateral, movement of the car. The information is used to correct the car in the event of oversteer or understeer
- RSC (Roll over stability control) is a function which monitors the tilt angle rate. If the driver turns the steering wheel quickly, during an avoidance maneuver for example, and the car is likely to tip over, the tilt angle sensor registers the rate at which the tilt angle is changing. The DSTC system rights the car. RSC (roll over stability control) is only available on the XC90
- Emergency Brake Assistance is a new function found in cars equipped with DSTC (dynamic stability and traction control) from model year 2002-. The function is integrated in the brake control module (BCM) and monitors the movement of the brake pedal. A sudden movement of the brake pedal (emergency braking) deploys the emergency brake assistance function to achieve optimum braking (more effective than normal braking). Information from the pedal position sensor is used to start the emergency brake assistance function. Full braking force is maintained for as long as the driver maintains or increases the pressure on the brake pedal. If the driver releases the brake pedal the emergency brake assistance function is immediately interrupted. Emergency brake assistance operates from approximately 10km/h up to the maximum speed. This function cannot be switched off.

CONTROL MODULE

The control module is integrated in the ABS hydraulic modulator and is located in the engine compartment. The control module contains the electrical valve coils for the different hydraulic valves.

The main function of the control module is to process the signals from the different sensors and to control the hydraulic pump and the electromagnetic hydraulic valves (inlet and outlet valves) in the ABS hydraulic modulator when controlling the:

- ABS

- EBD
- TRACS
- STC or
- DSTC.

Control modules with the DSTC (dynamic stability and traction control) function also have external sensors which sense the driver's steering wheel movements and the directional behavior of the car.

The control module communicates with directly connected components and other control modules via the Controller Area Network (CAN).

The control module checks calculations and all input and output signals via the built-in diagnostic functions. When the control module detects a fault certain functions are completely disengaged depending on the severity of the fault. At the same time a warning light comes on or a text message will be displayed depending on the fault (see table). When manually disengaging by activating the STC (stability and traction control) / DSTC (dynamic stability and traction control) switch (pressed in for approximately 1/2 second) all functions are disengaged except for the ABS, Electronic Brake force Distribution, emergency brake assistance and vehicle speed signal. In the event of the temperature of the brake discs being too high traction control is switched off to prevent damaging the brake caliper and brake discs. The general warning lamp is only lit by the brake control module (BCM) in the event of faults which affect the emergency brake assistance function. However it can be lit by other control modules which have been affected by faults in the brake control system.

From model year 2003 inclusive, only the traction control system can be disengaged manually. A traction loss warning lamp and a text message in the combined instrument panel are also used for models from this date.

	Warning lamp			
	ABS	Brake	Wheel spin / text display	General
ABS	**X**			
EBD		**X**		
TRACS			**X**	
STC			**X**	
DSTC			**X**	
EBA				**X**

Any diagnostic trouble codes (DTC) are stored in the control module memory. This information can be read off using VIDA via the data link connector (DLC) in the car.

When the car is driven the control module checks that a signal is received from the wheel sensors. When the car reaches 20 km/h for the first time (40 km/h if the stop (brake) lamp switch is activated) the control module checks the pump motor and the hydraulic valves by quickly activating them. A noise is then heard from the hydraulic pump, this is completely normal. The ABS function is first activated when the speed of the car exceeds approximately 7 km/h. Traction control functions from start.

SIGNALS, BRAKE CONTROL MODULE (BCM) WITH OR WITHOUT STC (STABILITY AND TRACTION

CONTROL) / TRACS (TRACTION CONTROL SYSTEM)

The table below summarizes the input signals to and output signals from the brake control module (BCM). The signal types are divided into directly connected signals, serial communication and Controller area network (CAN) communication. The following illustration displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: **Four Wheel sensors** (7/31, 7/32, 7/56, 7/57) **Pedal position sensor** (7/124)	**Directly connected:**
Via Controller Area Network (CAN) communication: **Central electronic module (CEM)** (4/56). Provides information about the car configuration. **Transmission control module (TCM)** (4/28). Provides information about the current gear, next gear and lock-up status (automatic transmission only). **Climate control module (CCM)** (3/112). Provides information that the driver has switched of the STC (Stability and traction control) function. **Engine control module (ECM)** (4/46): • Via the central electronic module (CEM): The signal indicates if the engine is running or not, the current engine speed (RPM) and the current torque • Provides information about the driver's intentions concerning acceleration or deceleration for calculating the stability control (STC only). **Differential electronic module (DEM)** (4/82). Provides information about the torque distribution to the rear wheels and the function status (All-wheel drive (AWD) only).	**Via Controller Area Network (CAN) communication:** **Driver information module (DIM)** (5/1): • Vehicle speed • Receives a request about the lighting of the ABS-, brake, and traction control warning lamp in the combined instrument panel • Receives a request about which text message should be displayed in the combined instrument panel. **Climate control module (CCM)** (3/112). Receives a request to light/turn off the indicator in the STC button. **Transmission control module (TCM)** (4/28): • Receives a request to delay a gearshift in the event of a substantial speed difference in the front wheels • Receives information about the position of the brake pedal sensor. **Engine control module (ECM)** (4/46): • Receives a request to decrease torque during stability control • Receives information about the position of the pedal. **Differential electronic module (DEM)** (4/82). Receives information about the brake function

	(AWD). **Road Traffic Information Module (RTI)** (16/45). Receives information about the rotation speed of the front wheels. Used to measure distance. **Phone Module (PHM)** (16/60). Receives information about the traveled distance, used when the Global Positioning System makes calculations.

Fig. 171: Brake Control Module Input And Output Signals (1 Of 2)
Courtesy of VOLVO CARS CORPORATION

SIGNALS, BRAKE CONTROL MODULES (BCM) WITH DSTC (DYNAMIC STABILITY AND TRACTION CONTROL)

The table below summarizes the input signals to and output signals from the brake control module (BCM). The signal types are divided into directly connected signals, serial communication and Controller area network (CAN) communication. The following illustration displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: **Four Wheel sensors** (7/31, 7/32, 7/56, 7/57) **Pedal position sensor** (7/124) **Activation unit DSTC** (Pedal pressure sensor) (8/46) **Two pressure sensors** (7/129, 7/139)	**Directly connected:** **Activation unit DSTC** (Pressure build-up valve) (8/46)
Via internal Controller Area Network (CAN) communication: **Sensor module DSTC** (7/164). Provides information about the yaw angle speed, lateral acceleration and, on cars with All-wheel drive (AWD), also forward acceleration.	**Via internal Controller Area Network (CAN) communication:**
Via Controller Area Network (CAN) communication: **Central electronic module (CEM)** (4/56). • Provides information about the car configuration • Provides information indicating that back-up (reverse) gear has been selected. This is to temporarily switch off the Active Yaw Control function (manual gearboxes only). **Transmission control module (TCM)** (4/28). • Provides information indicating that back-up (reverse) gear is selected to temporarily switch off the Active Yaw Control function (automatic transmission only) • Provides information about the current gear, next gear and lock-up status (automatic transmission only). **Climate control module (CCM)** (3/112). Provides information that the driver has switched of the traction control function. **Steering wheel angle sensor module (SAS)** (4/68). Provides information: • about the position of the steering wheel to calculate the position of the car • about whether the steering wheel is turned to the left or right	**Via Controller Area Network (CAN) communication:** **Driver information module (DIM)** (5/1): • Vehicle speed • Receives a request to light the ABS, brake, and traction control warning lamp in the combined instrument panel • Receives a request about which text message should be displayed in the combined instrument panel. **Climate control module (CCM)** (3/112). Receives a request to light/turn off the indicator in the DSTC button. **Transmission control module (TCM)** (5/1): • Receives a request to delay a gearshift in the event of a substantial speed difference in the front wheels • Receives information about the position of the pedal. **Engine control module (ECM)** (4/46): • Receives a request to decrease the torque during stability control • Receives information about the position of the pedal.

• about the speed at which the steering wheel is turned • about the status of the steering wheel angle sensor module (SAS) • about whether the steering wheel angle signal is OK. **Engine control module (ECM)** (4/46): • Via the central electronic module (CEM): The signal indicates if the engine is running or not, the current engine speed (RPM) and the current torque • Indicates current engine torque when calculating the traction control. **Differential electronic module (DEM)** (4/82). Provides information about the torque distribution to the rear wheels and the function status (All-wheel drive (AWD) only).	**Differential electronic module (DEM)** (4/82). Receives information about the brake function (AWD). **Phone Module (PHM)** (16/60). Receives information about the traveled distance, used when the Global Positioning System makes calculations. **Road Traffic Information Module (RTI)** (16/45). Receives information about the rotation speed of the front wheels. Used to measure distance.

Courtesy of VOLVO CARS CORPORATION

CAR BODY (2003-2012)

CAR BODY

CAR BODY DESIGN

Fig. 173: Identifying Car Body Design
Courtesy of VOLVO CARS CORPORATION

The XC90 is based on a passenger car chassis with unitary construction. This gives a low center of gravity, ensuring good directional stability and countering any tendency to roll over.

The shape of the XC90 body is based on the same basic design as the V70 body. Front and rear crumple zones absorb collision forces. The passenger compartment has a safety cage in which the door sills, posts, cantrails and doors are reinforced.

An aluminum member is spot-welded and screwed into place between the ends of the front side members. Steel plugs have been pressed into the aluminum member so that it can be welded into place.

The members in the front and rear doors form an important part of the reinforcement of the passenger compartment. The members are manufactured of boron steel.

Body with extremely high torsional rigidity.

A rigid body has a positive impact on active safety, sound level and collision safety (particularly in the event of side impacts).

There are two types of chassis applications, soft (USA) and hard (EU).

SURFACE TREATMENT/OUTER PANELS

Fig. 174: Identifying Surface Treatment/Outer Panels
Courtesy of VOLVO CARS CORPORATION

1. Panels
2. Zinc
3. Phosphate
4. Primer
5. Undercoat
6. Paint
7. Clear varnish
8. Underseal.

Paint

All paints are water based.

PASSIVE SAFETY

Fig. 175: Identifying XC90 Structure
Courtesy of VOLVO CARS CORPORATION

In terms of collision safety, the XC90 has the same design solutions found in other Volvo cars. An SUV is a tall vehicle. This means that in a collision, it will hit other cars at a higher level than a passenger car.

To reduce the risks of damage and injury from this type of impact, the front end subframe has been supplemented with a lower crossmember which is at the same height as the bumper on a conventional passenger car. This lower member is integrated in the structure of the XC90 and is hidden behind the spoiler. This reduces the damage to the other car, allowing its safety system to be fully utilized.

FRONT CRUMPLE ZONE

Fig. 176: Identifying Crumple Zones
Courtesy of VOLVO CARS CORPORATION

- In the front crumple zone the collision forces are transferred to the heavily reinforced passenger compartment by three braking crumple zones
- Two lower crumple zones, the front side members and the subframe transfer the force on to the body through the door sills and floor
- The upper crumple zone, the upper side members transfer the force onwards to the body through the A-post and on to the cantrail and roof
- The collision force which goes via the A-post is also transferred to the doors.

REAR CRUMPLE ZONE

Fig. 177: Identifying Crumple Zones
Courtesy of VOLVO CARS CORPORATION

In the rear crumple zone, the collision force is transferred via the rear side members to the door sill and floor, and to the cantrail and roof via the D-post.

The doors, which are an important part of the passenger compartment reinforcement also absorb much of the collision force.

SIDE CRUMPLE ZONES

Fig. 178: Identifying Crumple Zones
Courtesy of VOLVO CARS CORPORATION

In the event of a side impact, the collision force is absorbed by the reinforced door sills and the A and B posts.

The roof member and part of the B-posts are made of brushed steel.

HIGH STRENGTH STEEL / BORON STEEL

Fig. 179: Identifying High Strength/Boron Steel
Courtesy of VOLVO CARS CORPORATION

HSS steel, general

Certain parts of the body are manufactured of steel with an increased yield and breaking point. HSS steel is used for a number of reasons:

- Partly to save weight, HSS plate is thinner than standard plate without compromising on the resistance and strength of the component
- partly when a component or section needs to be reinforced. For example at the sides where the body needs to be reinforced for greater impact protection.

Boron steel, general

Boron steel has particular advantages over other hardened steels. In particular it is very tough, yet can also be welded and shaped during manufacture. It also has a high resistance to fatigue and wear.

Boron steel is extremely hard and cannot be aligned or machined.

GALVANIZED BODY COMPONENTS

Fig. 180: Identifying Galvanized Body Components
Courtesy of VOLVO CARS CORPORATION

Galvanizing, general

There are three different methods when surface treating the body

- Electrolytic zinc galvanization
- Hot-dip zinc galvanization
- Hot-dip galvanization.

The method which is used for a particular component depends on factors such as where it will be used in the car. It may be treated on both side or only on one side, depending on whether it is an external component which needs a smooth surface or not.

Galvanized body components

All outer panels are galvanized except the roof.

PANEL MATERIALS

Fig. 181: Identifying Plastic Components
Courtesy of VOLVO CARS CORPORATION

Painted plastic components

The front and rear bumper covers are partly painted in the same color as the car.

The tailgate is painted the same color as the car.

Plastic components

Trim molding, sill trim panel, door mirrors and fender extension moldings are not painted.

Headlamps

The headlamp lenses are made of transparent plastic.

ALUMINUM/ PLASTIC

Fig. 182: Identifying Aluminum/ Plastic
Courtesy of VOLVO CARS CORPORATION

Aluminum

- The front bumper rail is made of aluminum. The bumper rail is point welded and screwed into position. Steel plugs have been pressed into the aluminum member so that it can be welded into place in the ends of the front side members.

Plastic

- The upper tailgate is made of plastic. Only available as a complete replacement part
- The drain hose for the sun roof in the A and D posts is made of plastic.

TWO PIECE TAILGATE

Fig. 183: Identifying Two Piece Tailgate
Courtesy of VOLVO CARS CORPORATION

Plastic / Sheet metal

- The upper section of the tailgate is manufactured from Urethane plastic with 30% glass fiber
- The tailgate consists of a frame and an outer panel which are bonded together. The outer panel cannot be replaced. Glass fiber and plastic adhesive is used for repairs
- The lower tailgate is made of sheet metal and can withstand a load of 150 kg when folded down.

CENTRAL ELECTRONIC MODULE (CEM) (2003-2004)

DESIGN

HEADLAMPS

Fig. 184: Headlamps
Courtesy of VOLVO CARS CORPORATION

The headlamps at the front of the car are operated by the light switch module (LSM) which is positioned on the dashboard to the left of the steering wheel. The signals between the light switch module (LSM) and the central electronic module (CEM) are transmitted via serial communication. Low and high beam are operated by moving the left-hand control stalk towards the steering wheel.

The power supply for the lamps is via two directly connected relays on the central electronic module (CEM). One relay is for low beam and the other for high beam. The power supply for low beam is also via a shunt so that faults in the lamp can be detected.

For Bi-Xenon lamps the reflector in the lamp housing is moved by an actuator motor when changing between high and low beam. The actuator motor is integrated in the lamp housing.

There are three versions of the light switch function. These are programmed using the diagnostic tool:

- Low beam in all switch positions except the parking light position (flex zero)
- The light switch functioning on the basis of: off, parking light, low beam (flexsted)
- Low beam always on regardless of the position of the light switch (flexlgt).

To detect problems with the low beam, the central electronic module (CEM) reads the power consumption of the circuit. If this falls below a certain threshold value a fault will be indicated. The general warning lamp lights in the driver information module (DIM) and a text message is displayed.

For Bi-Xenon lamps there is a connection from the actuator motor to the central electronic module (CEM). In the event of incorrect values, the central electronic module (CEM) lowers the length of the beam using the headlamp range adjustment function.

There are diagnostics for the light switch and the relays.

There are also diagnostic for the high and low beam function (actuator motor) for Bi-Xenon lamps.

PARKING LIGHTS / LICENSE PLATE LIGHTING

Fig. 185: Parking Lights And License Plate Lighting
Courtesy of VOLVO CARS CORPORATION

There are a number of lamps positioned around the car to mark its position. These are in the headlamps, tail lamps and on the front fenders (US model). The lamps light together with the license plate lighting when the light switch module (LSM) is in parking lamp mode or low beam is on.

The lamps are powered via a directly connected relay on the central electronic module (CEM). The rear parking lamps are supplied with power via two shunts (mounted on the rear electronic module (REM)), one for each side. This is so that the power consumption can be monitored and any fault in the lamps detected. The faults are detected by the rear electronic module (REM).

There are diagnostics for the relay, the rear parking lamps (via the rear electrical module (REM)) and the light switch.

HEADLAMP RANGE ADJUSTMENT (CERTAIN MARKETS)

Fig. 186: Headlamp Range Adjustment
Courtesy of VOLVO CARS CORPORATION

There are two motors on the reverse of the headlamps. These angle the headlamps upwards or downwards to control the range of the beam.

The motors are controlled by a thumb wheel which is located in the light switch module (LSM) on the left of

the dashboard. If the thumb wheel is turned, information is transmitted to the motors which adjust the headlamps accordingly.

There are diagnostics for the headlamp range adjustment.

AUTOMATIC RANGE ADJUSTMENT (BI-XENON)

There are two motors on the reverse of the headlamps. These angle the headlamps upwards or downwards to control the range of the beam.

The motors are controlled by signals from a position sensor at the rear axle. The sensor detects the angle of the car under different load conditions and sends this information so that the central electronic module (CEM) can determine whether the lamps need to be raised or lowered.

There are diagnostics for the headlamp range adjustment.

FRONT FOG LAMPS

Fig. 187: Front Fog Lamps
Courtesy of VOLVO CARS CORPORATION

If the car has front fog lamps, these are in the bumper casing below the headlamps.

The fog lamps are operated via a button in the light switch module (LSM). An LED in the button lights when the fog lamps are activated. The light switch transmits data via serial communication to the central electronic module (CEM). The lamps are powered via a directly connected relay on the central electronic module (CEM).

There are diagnostics for the fog lamp relay.

TURN SIGNAL LAMPS / HAZARD WARNING SIGNAL FLASHERS

Fig. 188: Turn Signal Lamps And Hazard Warning Signal Flashers
Courtesy of VOLVO CARS CORPORATION

There are six lamps around the car to indicate direction changes. These are located in the front and rear lights and on the sides of the car in front of the front doors.

The turn signal lamps are operated using the left-hand control stalk.

To cancel the hazard warning signal flashers, where all the turn signal lights flash, press in the button for the hazard warning signal flasher. This is positioned in the middle of the dashboard by the center air vents.

The central electronic module (CEM) supplies the lamps with power via two shunts. These are located on the relay box by the central electronic module (CEM). A signal is also sent to the bulb in the hazard warning signal flasher switch when this function is activated.

The central electronic module (CEM) monitors the power consumption on each side to check for bulb faults. If the power consumption falls below a certain threshold value, a fault is indicated and the frequency of the signal to the bulbs is doubled on the side of the blown lamp.

There are diagnostics for the shunts.

COURTESY LIGHTING / KEY LIGHTING / GLOVE COMPARTMENT LIGHTING

Fig. 189: Courtesy Lighting, Key Lighting And Glove Compartment Lighting

Courtesy of VOLVO CARS CORPORATION

There are various lamps inside the passenger compartment, such as the courtesy lighting and glove compartment lighting for example. There are also LEDs around the keyhole in the ignition switch.

The lamps for the courtesy lighting are in the soundproofing panels on the driver and passenger sides. For the backseat the lamps are in the doors The lamp for the glove compartment is positioned on the left-hand inner side.

The lighting time can be programmed via the upper electronic module (UEM).

There are only diagnostics for the keyhole lighting.

HORN

Fig. 190: Horn
Courtesy of VOLVO CARS CORPORATION

There are two horns in front of the radiator. There are four switches in the steering wheel. The horn is activated when one of these is closed.

The signal continues for as long as the switch is closed.

The horn is also activated when the panic alarm button on the remote control is pressed (certain markets).

The power supply to the horns is via a relay in the relay box in the engine compartment.

There are diagnostics for the relay for the horn.

STARTER MOTOR

Fig. 191: Starter Motor
Courtesy of VOLVO CARS CORPORATION

The starter motor is on the left-hand side of the engine by the air cleaner (ACL) housing. The starter motor is powered directly from the battery. There is a solenoid on the starter motor to close the circuit. The central electronic module (CEM) activates a relay in the relay box in the engine compartment to act on the solenoid. This supplies the solenoid with power and closes the circuit for the starter motor.

The starter motor turns when the key is turned to position III in the ignition switch.

There are different functions which prevent starting, depending on whether the car has an automatic or manual transmission. The central electronic module (CEM) also has an electronic immobilizer function which communicates with a transponder in the key.

- Cars with manual gearboxes have a sensor in the clutch pedal. The clutch pedal must be depressed to allow starting (certain markets)
- In cars with type 4T65EV automatic transmissions, a signal is transmitted from the gear-shift position sensor to the transmission control module (TCM) which then sends a directly connected signal to the central electronic module (CEM)
- In cars with AW automatic transmissions, a directly connected signal is transmitted directly from the gear-shift position sensor to the central electronic module (CEM).

There are diagnostics for the relay for the starter motor.

REAR WINDOW LIFT MECHANISMS

Fig. 192: Identifying Rear Window Lift Mechanisms
Courtesy of VOLVO CARS CORPORATION

The rear side windows are operated by motors in the doors. The switches for operating the windows are in the door panels. The windows can also be operated from the driver's door module (DDM).

The function is controlled by five relays on the central electronic module (CEM). Depending on whether the control switch is moved up or down, the relays are activated to carry out the requested operation.

Two relays guide the window up on the right and left-hand sides. Two different relays guide the window down. A further relay controls the power supply.

When operated from the driver's position, information is transmitted via the controller area network (CAN) from the driver's door module (DDM) to the central electronic module (CEM) which sends out signals to the relays.

There are diagnostics for the relays for the rear window lift mechanisms.

FUEL PUMP

Fig. 193: Fuel Level Sensor
Courtesy of VOLVO CARS CORPORATION

The fuel pump (FP) is located on the inside of the fuel tank on the right-hand side. The pump is checked by the

central electronic module (CEM) which operates a relay. This relay controls the power supply to the pump and is directly connected to the central electronic module (CEM).

The central electronic module (CEM) uses the controller area network (CAN) to communicate with the engine control module (ECM) to control the fuel pump (FP). There is also a hardwire connection between the engine control module (ECM) and the central electronic module (CEM). This is used to transmit a pulsed signal to operate the fuel pump (FP). This allows the pump to function if there is a fault in the controller area network (CAN).

The central electronic module (CEM) also communicates with the supplemental restraint system (SRS) module via the controller area network (CAN). In the event of a collision, the supplemental restraint system module (SRS) transmits data and the central electronic module (CEM) shuts off the fuel pump (FP).

There are diagnostics for the input signal from the engine control module (ECM) and for the relay for the fuel pump (FP).

WASHER / WIPERS

Fig. 194: Washer And Wipers
Courtesy of VOLVO CARS CORPORATION

The windshield wipers are powered by a motor positioned under the cowl. There are also headlamp wipers. There are also washer nozzles on the hood and bumper cover for cleaning the windshield and headlamps. The washer nozzles are connected to a pump motor on the windshield washer reservoir at the front right of the engine compartment.

For cars with five doors, there is a wiper and washer nozzle for the rear windshield. The washer nozzle is connected to a separate pump on the windshield washer reservoir.

The windshield wipers are operated using the right-hand control stalk. There are three positions: intermittent, low speed and high speed. The time between strokes for intermittent wiping is adjusted using a ring on the control stalk.

Pull the control stalk towards the steering wheel to clean the windshield. The washer and wipers for the headlamps are activated at the same time. The headlamp wipers operate for as long as washing is activated. They are not activated when only the windshield wipers are activated.

Push the control stalk away from the steering wheel to clean the rear windshield. There is a button at the end of the control stalk to control the rear wiper.

Information about the position of the control stalk is transmitted to the central electronic module (CEM) on the controller area network (CAN). The central electronic module (CEM) also receives a signal from the wiper motor if the wipers are in the park position.

The central electronic module (CEM) also monitors the windshield washer reservoir level via a level sensor in the reservoir. The switch in the level sensor closes if the level falls below one liter. A text message indicating that the windshield washer fluid needs to be topped up then lights in the driver information module (DIM).

The power supply for the rear windshield wiper is via a directly connected relay on the rear electronic module (REM). Other wipers and the washer motors are supplied with power via relays in the engine compartment.

There are diagnostics for the windshield wipers.

HEATED SEATS (CERTAIN MARKETS)

Fig. 195: Heated Seats
Courtesy of VOLVO CARS CORPORATION

There are heater pads in the cushions and backrests to warm the seats. These are controlled by a control module under the seat. A thermistor on the heater pad detects the heat level.

The information between the control module and the central electronic module (CEM) is transmitted using serial communication. This data contains status information, diagnostic information and signals to control the heat level.

The seat heaters are operated using a switch to the right of the climate control module (CCM). The heat can be set to high or low. These temperatures can be programmed using the diagnostic tool.

There are diagnostics for the seat heaters.

SPEED SENSITIVE POWER STEERING

Fig. 196: Speed Sensitive Power Steering
Courtesy of VOLVO CARS CORPORATION

If the car has speed dependent power steering to control the steering assistance, there is a stepper motor which controls a hydraulic valve on the steering gear.

The stepper motor is operated by the central electronic module (CEM) and checked via four outputs in the central electronic module (CEM). Signals are transmitted from the central electronic module (CEM) to set the motor to the correct position for the speed of the car. The motor deploys the valve on the steering gear to the required degree and regulates the oil in the steering gear to reduce or increase the servo assistance. The steering assistance increases at lower speeds and is reduced at higher speeds.

There are diagnostics for the power steering.

DIAGNOSTIC FUNCTIONS

GENERAL INFORMATION

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. The control module can store up to 10 diagnostic trouble codes (DTCs).

If a fault disappears for any reason after the diagnostic trouble code (DTC) has been permanently stored in the control module, information about the fault remains in the control module.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function. The on-board diagnostic (OBD) system can identify 275 different faults in the form of diagnostic trouble codes (DTCs).

This function can also be used to read off whether the fault is still present (permanent) or whether it has now ceased (intermittent) after the diagnostic trouble code (DTC) has been stored.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF INPUT AND OUTPUT SIGNALS, CEM

This function can be used to continuously read off the values and status of the control module's input and output signals.

The following parameters can be read off:

- the status of the relay for extended X supply. The relay controls the power supply for the following functions: parking heater, power driver's seat and "after blow" for the air conditioning (A/C) system. The relay is activated in key positions I, II and III when the drivers door is opened (10 minutes), driver's door is closed and key position 0 (1 minute) and when one of the above functions is activated
- the status of the relay for extended X2 supply (AUT). Controls the power supply to the gear selector module (GSM). The relay is activated in key positions I, II, III, 0 or out for 10 seconds
- the status of the relay for the park neutral position (PNP) switch
- the status of the relay for the starter motor (activation signal from the central electronic module (CEM) to the relay)
- the status of the relay to raise the rear left-hand window. The relay is only active when the window lift mechanism is operated via the switch in the driver's door
- the status of the relay to lower the rear left-hand window. The relay is only active when the window lift mechanism is operated via the switch in the driver's door
- the status of the relay to raise the rear right-hand window. The relay is only active when the window lift mechanism is operated via the switch in the driver's door
- the status of the relay to lower the rear right-hand window. The relay is only active when the window lift mechanism is operated via the switch in the driver's door
- the status of the relay for the child lock (blocks operation of the rear window lift mechanisms). Note that when the function is activated, (i. e. the LED lit), the relay which supplies the rear window lift mechanisms is not activated. The read off gives the status of the relay
- status of the relay for high beam
- status of the relay for low beam
- status of the spot lamp relay
- status of the parking lamp relay
- status of the relay for the daytime running lamps
- status of the relay for the front fog lamps
- status of the relay for the windscreen wipers, off or on
- status of the relay for the windscreen wipers, high speed
- status of the relay for the washer motor
- status of the relay for the headlamp washer
- status of the relay for the horn
- status of the power supply (S-, X-, 15-, 50- and 30-supply)

- status of the key position
- status of the L signal (from the generator (GEN)). Ignition on ~0V, engine running ~1v
- status of the confirmation from the gear-shift position sensor about whether start (starter motor relay activated) is possible
- the status of the frequency signal from the engine control module (ECM) for the fuel pump (FP) relay
- the status of the windscreen washer reservoir level
- the status of the windscreen wipers
- the status of the driver's door (open or closed)
- the status of the passenger door (open or closed)
- the status of the left rear door (open or closed)
- the status of the right rear door (open or closed)
- the status of the tailgate (open or closed)
- the status of the lock switch for the driver's door (from the driver door module (DDM))
- the status of the lock switch for the passenger door (from the passenger door module (PDM))
- the status of the lock switch for the left-hand rear door
- the status of the lock switch for the right-hand rear door
- status hood alignment (the parameter indicates if the hood was open or closed when the alarm was activated).
- the status of the signal from the relay switch for the fuel pump (FP)
- the status signal from the supplemental restraint system (SRS) module indicating whether the Airbag is OK
- the status of the switch for the hazard warning signal flasher
- the status of the button lamp for the hazard warning signal flashers
- the status of the key ring lighting
- the status of the indication LED for the alarm
- the status of the fuel pump (FP)

NOTE: **The seat belt switches are connected to the Supplemental Restraint System Module (SRS) on model year 2003 and onward. They cannot then be read from the Central Electronic Module (CEM).**

-
- the voltage of the seat belt switch, driver's side
- the voltage at the seat belt switch, passenger side
- output, pulse width modulated signal to the courtesy lighting
- speed signal (for accessories). If the car is raised for this read off, ensure that the wheels are stationary when the gear selector is moved to position P (automatic transmissions). Note that diagnostic trouble codes (DTCs) may be stored in the ABS system if the front wheels are stationary and the rear wheels rotate
- the status of the pulse width modulation (PWM) signal for headlamp beam height control

- the status of the pulse width modulation (PWM) signal from the left-hand Xenon lamp (65%-90%)
- the status of the pulse width modulation (PWM) signal from the right-hand Xenon lamp (65%-90%)
- the fault status for the xenon lamp
- the status of the infotainment relay.

READING OFF PARAMETERS, IMMOBILIZER

- **ID CODE RECEIVED**

  Indicates whether the central electronic module (CEM) has received a key code (Transponder ID code). This applies whether the key is stored as an approved key or not. YES or NO. However, the key must be of the correct type - intended for this type of Volvo.

- **ID CODE STORED**

  ID CODE STORED Indicates whether the last received key code (transponder ID code) is stored as an approved key code in the central electronic module (CEM) memory. YES or NO.

- **RANDOM CODE TO TP**

  Indicates whether the central electronic module (CEM) is transmitting a random code to the key which presupposes that the key code is stored. SEND or DO NOT SEND.

- **RESPONSE FROM TP**

  Indicates whether the central electronic module (CEM) is receiving a response from the key (via the antenna ring) which presupposes that the key code is stored. YES or NO. YES is also displayed for a key belonging to another car of the same type, with the same key ID but a different security code.

- **TP STATUS OK**

  Indicates whether all of the following conditions are fulfilled: 1) Key code (transponder ID code) is stored. 2) The key has the car's security code (the key belongs to the car). 3) Communication (random code and response) is OK. YES or NO.

- **KEY TYPE**

  Indicates whether the ignition key used is a MASTER KEY or a SERVICE KEY

- **KEY NO.**

  Indicates which of the vehicle's keys is in the ignition switch. Each key programmed into the central electronic module (CEM) is given a serial number from 1 to 6. NO. 1 - NO. 6.

- **NUMBER OF KEYS**

Indicates how many keys (key codes) are stored in the central electronic module (CEM) memory, 1-6. A maximum of six keys can be stored.

- **IMMO MODE**

  Indicates the mode of the immobilizer in the central electronic module (CEM), NORMAL or PROGRAMMABLE. In NORMAL it is not possible to change the content (add/erase key codes) in the immobilizer. In PROGRAMMABLE mode the immobilizer can be programmed (add/erase key codes). In this mode the engine cannot be started.

  After a programming has been carried out, VIDA returns to NORMAL mode.

  HINT: If communication problems occur during programming, the central electronic module (CEM) remains in PROGRAMMABLE mode.

  HINT: To correct this, remove fuse 11C/32 from the fusebox in the passenger compartment and reinstall it so the central electronic module (CEM) returns to NORMAL mode again.

- **ECM DATA RECEIVED**

  Indicates whether the Control area network (CAN) signal containing Immo ECM data transmitted is received within a given (maximum) time. This signal is transmitted by the engine control module (ECM) to the central electronic module (CEM) on the high speed network, when the ignition is switched on. YES or NO

- **ECM START SIGNAL**

  Indicates whether the Control area network (CAN) signal transmitted by the engine control module (ECM) to the central electronic module (CEM) on the high speed network after an IMMO CHECK is completed, when the ignition is switched on, allows the engine control module (ECM) to be start (POS) the engine or not (NEG). The following conditions must be met before the engine control module (ECM) will allow the engine to be started. The transponder check must have been successful (the key code, transponder ID, is stored and the security codes for the key and the central electronic module (CEM) correspond). The immobilizer check must have been successful (the codes in the central electronic module (CEM) and the engine control module (ECM) correspond).

- **SECURITY CODE RECEIVED (VIN-CODE ok)**

  Indicates if an approved security code form the Engine control module (ECM) has been received by the Central electronic module (CEM).

- **IMMO RELAY STATUS**

  Indicates the status of the immobilizer's request to the starter motor relay. If the immobilizer permits the relay to connect the starter motor, START POSSIBLE is displayed. IF not, START NOT POSSIBLE is displayed.

ACTIVATING COMPONENTS AND FUNCTIONS

This function can be used to activate components and functions which affect the outputs of the central electronic module (CEM).

The following components can be activated:

- deactivation of the relay for extended power supply
- activating the relay for extended X2 supply
- activating the relay for the park neutral position (PNP) switch
- activating the relay to raise the rear left-hand window
- activating the relay to lower the rear left-hand window
- activating the relay to raise the rear right-hand window
- activating the relay to lower the rear right-hand window
- activating the relay for high beam
- activating the relay for low beam
- activating the spot lamp relay (accessory)
- activating the relay for the parking lamps
- activating the relay for the daytime running lamps
- activating the relay for the front fog lamps
- activating the relay for the windscreen wipers off/on
- activating the high speed windscreen wiper relay
- activating the relay for the front washer motor
- activating the relay for the headlamp washer
- activating the relay for the horn
- activating the frequency signal from the engine control module (ECM) for the fuel pump (FP) relay
- activating the speed signal (for accessories)
- activating the signal to the switch for the hazard warning signal flashers. To switch off the hazard warning signal flashers, they must be activated and reset again. The function is switched off if the button in the car is pressed once
- activating the key ring lighting (the key ring lighting does not light if the car is locked. The window can be open however, to allow communication with the data link connector (DLC))
- activating the signal for the alarm LED
- activating the pulse width modulated signal for the courtesy lighting
- activating the relay for preheating the leak diagnostic pump
- activating the infotainment relay.

READING OFF AND PROGRAMMING DATA

This function allows programmed data to be read off or data such as customer parameters to be programmed in.

NOTE: If possible, all data must be read out from the control module before replacement. After replacement the relevant data must be programmed into the

new control module.

Customer parameters can be programmed for approach lights, seat heaters, post drying and daytime running lamps.

Seat heater: First read off the data that is programmed in the central electronic module (CEM). Answer, for example, 37C. Then enter the temperature desired by the customer, for example 41C. After programming, the new data must be saved in the control module memory. The following values can be programmed in: 0, 10C, 28C, 30C, 31C, 32C, 33C, 34C, 35C, 36C, 37C, 38C, 39C, 40C, 41C, 43C. The left and right-hand seats are programmed individually and there are two settings that can be selected by the customer, high or low.

Approach lights: First read off the data that is programmed in the central electronic module (CEM). Answer, for example, 30 seconds. Then enter the time desired by the customer, for example 90 seconds). After programming, the new data must be saved in the control module memory. The following values can be programmed in: 0, 30, 60 and 90 seconds.

Post drying: First read off the parameters programmed in the central electronic module (CEM). Reply for example the function is not set. Then enter if the customer wants post drying (the function is set). After programming, the new parameters must be saved to the control module memory. The following values can be entered: Off or on.

Daytime running lamps: First read off the data that is programmed in the central electronic module (CEM). For example, daytime running lamps off. Then enter if the vehicle is to have daytime running lamps (daytime running lamps on). After programming, the new data must be saved in the control module memory. The following values can be programmed in: Off or on. There are two versions of off. Dipped headlamps can be switched on in all light switch positions apart from the P position. The dipped headlamp beam can also be adjusted.

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N.

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the central electronic module. When ordering software, the hardware and the software in the car is compared to the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

The control module is in a relay box under the soundproofing panel on the driver's side. The control module needs to be removed from the relay box to be replaced.

When installing a completely new central electronic module in the car, PIN codes for the central electronic module, immobilizer and transponder (key) are downloaded into the control module. The PIN codes are loaded automatically during the ordering process in VIDA (Volvo scan tool). The PIN codes are retrieved from the Volvo Central Database and sent with the software package when software is ordered for the new control module. Each transponder key must however, be programmed as each key has a unique code which must be stored in the central electronic module.

Because of the unique PIN codes, the central electronic modules cannot be moved between cars.

Three customer parameters can be programmed into the central electronic module. These customer parameters are stored in the control module but not in the Volvo central database. This means that the customer parameters must be reprogrammed when the hardware is replaced.

The customer parameters which can be programmed are:

Seat temperature

- There are two values that can be programmed: low temperature and high temperature. Programming must be carried out so that the high temperature setting is higher than the low temperature setting.

Approach lights

- The approach lights can be programmed to stay on for a longer or shorter time according to the wishes of the customer. The factory setting is 30 seconds. The time can be set to 0, 30, 60 or 90 seconds.

Daytime running lamps

- The daytime running lamps can be programmed in three ways:
  1. Low beam in all switch positions except the parking light position (Flex zero)
  2. The light switch functioning on the basis of: off, parking light and low beam (Flex standard)
  3. Low beam always on regardless of the position of the light switch (Flex low).

NOTE: It is essential that the legal requirements of each country are followed.

FUNCTION

HEADLAMPS

Fig. 197: Headlamp Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

Depending on the position of the knob, the light switch module (LSM) (3/111) transmits information via serial communication to the central electronic module (CEM) to turn on low beam. The central electronic module (CEM) (4/56) then transmits a control signal to activate the low beam relay (2/62). The bulbs are then supplied with power.

To change to high beam, the left-hand control stalk is pulled towards the steering wheel. The control area network (CAN) signal from the steering wheel module (SWM) (3/130) is transmitted to the central electronic module (CEM) which activates the high beam relay (2/63) and supplies power to the high beam. For Bi-Xenon lamps, the position of the reflector is also changed so that the Xenon lamp is on at high beam.

The central electronic module (CEM) also transmits a CAN signal to the driver information module (DIM) (5/1) to light the indicator lamp for high beam.

There is a Limp Home function that ensures that low beam still works if there is a fault in the control area network (CAN). For Bi-Xenon lamps the beam is then set to the shortest range.

PARKING LIGHTS / LICENSE PLATE LIGHTING

Fig. 198: Parking Lights And License Plate Lighting Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

The parking lamps (10/11-12, 10/17-18) and license plate lighting (10/3) lights when:

- The knob in the light switch module (LSM) (3/111) is in the low beam position
- The knob in the light switch module (LSM) is in the parking lamp position
- Low beam is lit via the low beam automatic function.

The lamp switch module (LSM) transmits data using serial communication to the central electronic module (CEM) (4/56) to activate the lamps.

The lamps are supplied with power via a relay (2/61) which is activated by the central electronic module (CEM). The license plate lighting, the front parking lamps (also on the front fenders for US models) are directly supplied with power. The rear parking lamps are supplied by two shunts (20/28, 20/33) on the rear electronic module (REM) (4/58) so that blown bulbs can be detected.

In the event of a bulb fault for the rear parking lamps, data is transmitted on the control area network (CAN) from the rear electronic module (REM) to the driver information module (DIM) (5/1) and a text message is displayed.

There is a Limp Home function for the parking lamps so that they will work even if there is a fault in the control area network (CAN) or in the serial communication between the light switch module (LSM) and the central electronic module (CEM).

HEADLAMP RANGE ADJUSTMENT (CERTAIN MARKETS)

Fig. 199: Headlamp Range Adjustment Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

Headlamp range adjustment is controlled by the central electronic module (CEM) (4/56). The central electronic module (CEM) communicates with the light switch module (LSM) (3/111) using serial communication.

If the thumb wheel in the light switch module (LSM) is turned, information about the position of the wheel is transmitted to the central electronic module (CEM). The central electronic module (CEM) transmits a pulse width modulation (PWM) signal to the actuator motors (6/38-39) with the pulse ratio set according to the position of the thumb wheel. The headlamp range can be adjusted in 16 stages.

AUTOMATIC RANGE ADJUSTMENT (BI-XENON)

Fig. 200: Automatic Range Adjustment Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

Automatic headlamp range adjustment is controlled by the central electronic module (CEM) (4/56). The position sensor (7/120) on the rear suspension transmits signals to the rear electronic module (REM) (4/58) about the angle of the car in terms of the load conditions.

The rear electronic module (REM) transmits this data via the control area network (CAN) to the central electronic module (CEM) which compares the information with the table for the relevant model. The table is stored in the central electronic module (CEM).

The actuator motors (6/38-39) are then operated from the central electronic module (CEM) via a PWM signal, the pulse ratio of which depends on the angle the lamps need to be set to.

FRONT FOG LAMPS

Fig. 201: Front Fog Lamps Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

The front fog lamps (10/5-6) are activated by pressing the button for the front fog lamps in the light switch module (LSM) (3/111). The light switch module (LSM) transmits data to the central electronic module (CEM) (4/56) to light the lamps. The central electronic module (CEM) activates the relay (2/34) and the bulbs are supplied with power via the relay.

TURN SIGNAL LAMPS / HAZARD WARNING SIGNAL FLASHERS

Fig. 202: Turn Signal Lamps And Hazard Warning Signal Flashers Input And Output Signals

Courtesy of VOLVO CARS CORPORATION

This function is controlled by the left control stalk. The steering wheel module (SWM) (3/130) sends data to the central electronic module (CEM) (4/56) to activate the turn signal lamps via the control area network (CAN). The central electronic module (CEM) transmits information to the driver information module (DIM) (5/1) to activate the turn signal indicator lamp and powers the turn signal lamp via a shunt (20/32, 20/34).

The power supply is pulsed and the turn signal lamps are activated 90 times per minute.

The hazard warning signal flasher is activated by closing the switch (3/6) and transmits a signal to the central electronic module (CEM) to start the function. The central electronic module (CEM) transmits a signal in the same way as above, but to both sides. The central electronic module (CEM) also transmits a signal to the bulb in the switch to indicate that the hazard warning signal flashers are on. If the ignition key is in position I or II, there is a clicking sound from the driver information module (DIM). If the ignition is switched off, there is no sound, but the hazard warning signal flashers continue to flash.

If a fault occurs with a lamp, the central electronic module (CEM) detects the reduction in power consumption and the frequency is doubled on the side where the fault occurred.

COURTESY LIGHTING / KEY LIGHTING / GLOVE COMPARTMENT LIGHTING

Fig. 203: Courtesy Lighting, Key Lighting And Glove Compartment Lighting Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

The courtesy lighting (10/122-123, 10/125-126), keyhole (16/65) and glove compartment lighting (10/29) are controlled via the central electronic module (CEM) (4/56). All other interior lighting is controlled by the upper electronic module (UEM) (4/70). The central electronic module (CEM) powers the lamps which it controls directly.

The lamps are powered if a door is opened (3/74-77), or when the upper electronic module (UEM) transmits a request via the control area network (CAN). The upper electronic module (UEM) transmits a request when it has received an unlock command from one of the remote controls. If a door is opened, the central electronic module (CEM) sends a control area network (CAN) signal to the upper electronic module (UEM) to light the lighting it controls.

The glove compartment lighting (10/29) is supplied with power directly from the central electronic module (CEM) when the switch by the lamp is activated when the glove compartment is opened.

HORN

Fig. 204: Horn Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

The horn is operated when the steering wheel module (SWM) (3/130) receives a signal from the switches (3/37) in the steering wheel. The steering wheel module (SWM) sends data to the central electronic module (CEM) (4/56) via the control area network (CAN) indicating that the switch is closed. The central electronic module (CEM) activates the relay (2/17) for power supply to the horn.

There is also a signal directly connected from the steering wheel module (SWM) to the central electronic module (CEM). This is used if there is a fault in the control area network (CAN). This is a Limp-Home function.

STARTER MOTOR

Fig. 205: Starter Motor Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

Manual transmissions

The starter motor (6/25) is operated by turning the key in the ignition switch (3/1) to position III.

- For transmissions **with** a clutch interlock (certain markets), a signal is transmitted from the ignition switch to the engine control module (ECM) (4/46). The engine control module (ECM) detects the position of the clutch pedal sensor (7/123). The engine control module (ECM) transmits data to the central electronic module (CEM) (4/56) via the control area network (CAN) about the position of the pedal. The central electronic module (CEM) requires a signal that the clutch is pressed down and that the key is in position III before it will send a signal to the relay (2/35). When the relay is activated, the solenoid in the starter motor is powered
- For transmissions **without** clutch interlock, the central electronic module (CEM) (4/56) activates relay 2/35 and powers the solenoid in the starter motor (6/25).

The starter motor turns for as long as the key is in position III. If the engine has been started once, there is a Limp Home function so that the engine can be started again even if there is a fault in the control area network (CAN). This function is active for a brief period after the key is removed from the ignition switch. After this time the car will not start because there is no communication for the immobilizer between the central electronic module (CEM) and the engine control module (ECM).

Automatic transmission

The starter motor (6/25) is operated by turning the key in the ignition switch (3/1) to position III.

- For transmission 4T65EV, a signal is transmitted from the gear-shift position sensor (3/71) via the transmission control module (TCM) (4/28) to the central electronic module (CEM) (4/56) indicating that the gear selector is in position P/N
- For AW transmissions the signal is transmitted directly from the gear-shift position sensor to the central electronic module (CEM). The central electronic module (CEM) requires this signal and a signal indicating that the key is in position III before it will send a signal to the relay (2/35). When the relay is activated, the solenoid in the starter motor is powered.

The starter motor turns for as long as the key is in position III. If the engine has been started once, there is a Limp Home function so that the engine can be started again even if there is a fault in the control area network (CAN). This function is active for a brief period after the key is removed from the ignition switch. After this time the car will not start because there is no communication for the immobilizer between the central electronic module (CEM) and the engine control module (ECM).

REAR WINDOW LIFT MECHANISMS/CHILD LOCK

Fig. 206: Rear Window Lift Mechanisms/Child Lock Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

The rear window lift mechanisms are operated using switches (3/85-86) in the door panels. Relays 2/116 or 2/118 for the left-hand side and relays 2/117 or 2/119 for the right-hand side are activated in the central electronic module (CEM) (4/56) depending on whether the window is to move up or down.

When the window lift mechanisms are operated from the driver's position, data is transmitted from the driver's door module (3/126) via the control area network (CAN) to the central electronic module (CEM) which transmits a signal to the correct relay.

There is a switch in the driver's door module (DDM) to allow for child locking, where the windows can only be operated from the driver's position. When this is active, data is transmitted via the control area network (CAN) to the central electronic module (CEM) to disconnect relay 2/120. This breaks the circuit for the rear switches.

When the child lock is activated, the lighting in the rear switches goes out.

FUEL PUMP

Fig. 207: Fuel Pump Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) (4/56) receives a request from the engine control module (ECM) (4/46) via the control area network (CAN) to start the fuel pump (FP) (6/33). The central electronic module (CEM) then activates the relay (2/23) which supplies the fuel pump with power.

In the event of a collision in which the airbags are deployed, a signal is transmitted from the supplemental restraint system (SRS) module (4/9) via the control area network (CAN) to the central electronic module (CEM) which deactivates the relay for the fuel pump.

If the control area network (CAN) is not functioning, a pulsed signal to control the fuel pump (FP) is transmitted from the engine control module (ECM) to the central electronic module (CEM) via a directly connected cable.

WIPER / WASHERS FOR THE WINDSHIELD AND HEADLAMPS

Fig. 208: Wiper And Washers For The Windshield And Headlamps Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

The right-hand control stalk is moved downwards through three positions to operate the windshield wipers. The steering wheel module (SWM) (3/130) transmits information via the control area network (CAN) to the central electronic module (CEM) (4/56) about the selected position. The central electronic module (CEM) then activates relay 2/91 which supplies the wiper motor (6/1) with power in position 1. If high speed wiping is selected, relay 2/90 is also activated to power the motor in position 2.

The central electronic module (CEM) receives a signal from the motor when the wipers are in the parked position so that the wipers can be stopped in the correct position.

For intermittent wiping, the process is the same as for low speed, but the time between each stroke is set using the ring on the control stalk to one of eight positions between 1 and 27 seconds. The central electronic module (CEM) controls this once it has received information about intermittent wiping from the steering wheel module (SWM) via the control area network (CAN).

The windshield and headlamps are washed when the right-hand control stalk is moved towards the steering wheel. The steering wheel module (SWM) transmits information to the central electronic module (CEM) via the Control area network (CAN) to activate washing. The central electronic module (CEM) activates the relay 2/92 which powers the pump motor (6/2) and wiper motors (6/3-4) for the headlamps.

The central electronic module (CEM) receives a signal from the level sensor (7/5) in the windshield washer reservoir so that it can check the windshield washer reservoir level. The switch in the level sensor closes if the level falls below one liter. The central electronic module (CEM) sends the signal to Driver information module (DIM) (5/1) via the controller area network (CAN). The driver information module (DIM) displays a text message indicating that the windshield washer fluid needs to be topped up.

Rear windshield cleaning is activated when the right-hand control stalk is pushed away from the steering wheel. The steering wheel module (SWM) sends signals via the control area network (CAN) to the central electronic module (CEM) to activate rear windshield washing. The central electronic module (CEM) activates relay 2/93 to power the pump motor (6/30). At the same time the rear electronic module (REM) activates the tailgate wiper.

The wipers only operate at low speed if there is a fault in the control area network (CAN). If this is the case, the central electronic module (CEM) receives a directly connected signal from the steering wheel module (SWM).

There is no Limp Home function for the rear windshield washer and wiper.

HEATED SEATS (CERTAIN MARKETS)

Fig. 209: Heated Seats Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

The seat heaters are activated by pressing the switch to the right of the climate control module (CCM) (3/112). If the switch is pressed once, they are activated at high temperature. Pressing again will activate low temperature. Pressing a third time switches the heaters off.

The climate control module (CCM) transmits information via the control area network (CAN) to the central electronic module (CEM) (4/56) to activate the seat heaters. The central electronic module (CEM) sends back a

signal to the climate control module (CCM) to light the LED in the button. The central electronic module (CEM) compares the signal from the climate control module (CCM) with the programmed value for high/low temperature and transmits a pulsed signal to the control module for the seat heater (9/12-13) about the requested temperature. The number of pulses determines the power at which the control module will operate the seat heater. The control module also compares the value from the thermistor so that it can detect faults in the heater pad.

SPEED SENSITIVE POWER STEERING

Fig. 210: Speed Sensitive Power Steering Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) (4/56) receives data from the engine control module (ECM) (4/46) via the control area network (CAN) that the engine is running and information from the ABS system (4/16) about the speed of the car. From model year 2001 the ABS module is called the brake control module (BCM). The central electronic module (CEM) then operates the stepper motor (6/71) via the four outputs to set the stepper motor to the correct servo assistance level.

The central electronic module (CEM) checks the signals. If a fault is detected, the servo assistance is set to normal (approx.70km/h) and the system is disengaged. The central electronic module (CEM) also transmits a signal to the driver information module (DIM) (5/1) via the control area network (CAN) which lights the general warning lamp and displays a text message.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 211: Central Electronic Module Control module
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) controls the Controller area network (CAN) and acts as a bridge between the high and low speed networks and the data link connector (DLC). It also manages the following functions:

- Alarm (certain functions)
- Locks (certain functions)
- Immobilizer
- Headlamps
- Parking lights / license plate lighting
- Front fog lamps
- Headlamp range adjustment (certain markets)
- Automatic range adjustment (Bi-Xenon)
- Turn signal lamps
- High-mounted stop lamp
- Courtesy lighting / key lighting / glove compartment lighting
- Rear window lift mechanisms
- Fuel pump
- Wiper / washers for the windshield and headlamps
- Starter motor
- Speed sensitive power steering
- Electrically heated seats
- Horn.

The control module is installed as a separate unit in a relay box under the soundproofing panel on the driver's side. The control module is removed from the relay box for replacement.

The car configuration file is stored in the central electronic module (CEM). It contains information about the car VIN number, structure week and the equipment in the car. When replacing the central electronic module (CEM), the VIN cannot be read off until the software has been downloaded from the Volvo central database.

The central electronic module (CEM) communicates with components which are directly connected and also with other control modules and components via serial communication and the control area network (CAN).

The control module checks activations and input and output signals using an integrated diagnostic system A diagnostic trouble code (DTC) is stored if the control module detects an error. In certain cases the central electronic module (CEM) replaces the faulty signal with a substitute signal. Other control modules also communicate on the network with the central electronic module (CEM) if they have diagnostic trouble codes (DTCs) stored. This function is used when reading off diagnostic trouble codes (DTCs) without VIDA (Volvo scan tool).

Any diagnostic trouble codes (DTCs) are stored in the control module memory. This information can be read off using VIDA via the data link connector (DLC) in the car.

The easiest way to check if the central electronic module (CEM) is grounded and receiving power is to activate the hazard warning signal flasher. The central electronic module (CEM) is supplied with power if the function operates. Another way of checking that the central electronic module (CEM) is supplied with voltage and grounded is to activate one of the rear window lift mechanisms.

SIGNALS

The following table summarizes the input signals to and the output signals from the central electronic module (CEM). The signal types are divided into directly connected signals, serial communication and Controller area network (CAN) communication. The following illustration displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected:	**Directly connected:**
Back-up (reversing) lamp (3/10)	Starter motor, relay (x2) (6/25)
Windshield wiper motor (6/1)	Stepper motor, power steering (x 4) (6/71)
Windshield washer level sensor (7/5)	Headlamp range adjustment (6/38)
Control signal doors / tailgate (x 8) (3/74)	Windshield wiper, relay (x2) (6/1)
Horn switch (3/37)	Washer motor, relay (x 2) (6/2)
Stop lamp switch (3/9)	Horn, relay (16/10)
Seat belt buckle sensor (x 4) (3/93)	Stop lamps from the rear electronic module (REM) (4/58)
Fuel pump frequency signal (4/46)

Fig. 213: Central Electronic Module Input And Output Signals (2 Of 2)
Courtesy of VOLVO CARS CORPORATION

CENTRAL ELECTRONIC MODULE (CEM) (2005-2012)

DESIGN

GENERATOR (GEN) (ALTERNATOR CONTROL MODULE (ACM))

Fig. 214: Generator And Alternator Control Module
Courtesy of VOLVO CARS CORPORATION

CURRENT LIMITING

The central electronic module (CEM) checks and sometimes limits the current from the battery and generator.

The central electronic module (CEM) communicates with the alternator control module (ACM) via serial communication.

If there is a fault with current limitation, the general warning lamp will light in the driver information module (DIM) and a text message will be displayed.

STEERING WHEEL MODULE (SWM)

Fig. 215: Identifying Steering Wheel Module
Courtesy of VOLVO CARS CORPORATION

The steering wheel module (SWM) has the task of managing the signals for those functions which can be controlled via the steering wheel control stalks and buttons. The signals are transmitted using LIN

communication to the central electronic module (CEM). The central electronic module (CEM) forwards these signals on the controller area network (CAN) to the relevant control modules. The actual functions are not in the steering wheel module (SWM).

The steering wheel module (SWM) manages the control signals for the following functions:

- Volume control and CD track / radio selection
- Volume control during hands free carphone calls and menu selection for the phone module (PHM)
- Menu selection for traffic information
- Front windshield wipers and washers
- Rear windshield wiper and washer
- Cruise control
- Turn signal lamps
- High and low beam
- Trip computer and displaying/erasing text messages in the driver information module (DIM).

The steering wheel module (SWM) is integrated into the steering wheel bracket. The steering wheel must be removed to replace the steering wheel module (SWM). Control stalks, key pads and switches can be replaced as separate units.

Cars with DSTC also have a steering wheel angle sensor in the contact reel in the steering wheel module (SWM).

A simple way to ensure that the steering wheel module (SWM) is powered and grounded is to flash the headlamp high beam or to change the audio or carphone volume.

STEERING WHEEL BUTTONS

Fig. 216: Identifying Steering Wheel Control Buttons
Courtesy of VOLVO CARS CORPORATION

The steering wheel buttons control functions and menu selection for:

- Traffic information (option)

- Audio (option)
- Carphone (option)
- Cruise control (option).

The signals from the steering wheel buttons are transmitted via serial communication.

HEADLAMPS

Fig. 217: Headlamps
Courtesy of VOLVO CARS CORPORATION

WARNING: Both drive stages, which are built into the lamp housing, and the wiring for the Bi-Xenon lamps are high voltage.

The headlamps are operated via the light switch module (LSM). This is on the dashboard at the side of the steering wheel. The light switch module (LSM) uses serial communication to communicate with the central electronic module (CEM). Low and high beam are operated by moving the left-hand control stalk towards the steering wheel.

Low beam is powered directly by the central electronic module (CEM). High beam is powered via a directly connected relay in the central electronic module (CEM). The level of the supply voltage to the low beam is regulated by the central electronic module (CEM). When the supply voltage is sufficient (in excess of 13 V), pulse width modulation is used to maintain the voltage level at 13.0 V +/- 0.2 V. This does not apply to cars with Bi-Xenon lamps.

Cars with Bi-Xenon lamps are powered directly via the central electronic module (CEM) without pulse width modulation.

In Bi-Xenon lamps, the reflector in the lamp housing is moved by an actuator motor when changing between high and low beam. The actuator motor is integrated in the lamp housing.

To detect problems with the low beam, the central electronic module (CEM) reads the power consumption of the circuit. If this falls below a certain threshold value a fault will be indicated. The general warning lamp lights in the driver information module (DIM) and a text message is displayed.

There are also diagnostics for the high and low beam function (actuator motor) for Bi-Xenon lamps.

HEADLAMP RANGE ADJUSTMENT (CERTAIN MARKETS)

Fig. 218: Headlamp Range Adjustment
Courtesy of VOLVO CARS CORPORATION

There are two motors, one on each headlamp, which angle the headlamps upwards or downwards to control the range of the beam. The motors are on the rear of the headlamps.

The motors are controlled by a thumb wheel which is located in the light switch module (LSM) on the dashboard by the side of the steering wheel.

If the thumb wheel is turned, information is transmitted to the motors which adjust the headlamps accordingly.

There are diagnostics for the headlamp range adjustment.

AUTOMATIC RANGE ADJUSTMENT (BI-XENON)

There are two motors, one on each headlamp, which angle the headlamps upwards or downwards to control the range of the beam. The motors are on the rear of the headlamps.

The motors are controlled by signals from a position sensor at the rear axle. The sensor detects the angle of the car under different load conditions and sends this information via the rear electronic module (REM) so that the central electronic module (CEM) can determine whether the lamps need to be raised or lowered.

There are diagnostics for the headlamp range adjustment.

FRONT FOG LAMPS

Fig. 219: Front Fog Lamps
Courtesy of VOLVO CARS CORPORATION

If the car has front fog lamps, these are in the bumper casing below the headlamps.

The fog lamps are operated via a button in the light switch module (LSM). An LED in the button lights when the fog lamps are activated. The light switch module (LSM) uses serial communication to communicate with the central electronic module (CEM). The bulbs are powered via a directly connected relay in the central electronic module (CEM).

FRONT PARKING LAMPS

Fig. 220: Headlamps
Courtesy of VOLVO CARS CORPORATION

There are a number of lamps positioned around the car to mark its position. These are in the headlamps and tail lamps. The lamps light together with the license plate lighting when the light switch module (LSM) is in parking lamp mode or low beam is on.

The front parking lamps are powered directly via two outputs on the central electronic module (CEM). One of the outputs powers:

- the front left-hand parking lamp

- the left-hand parking lamps.

The other output powers:

- the front right-hand parking lamp
- the right-hand side parking lamps.

The rear parking lamps and license plate lighting are powered by the rear electronic module (REM).

There are diagnostics for the parking lamps.

TURN SIGNAL LAMPS / HAZARD WARNING SIGNAL FLASHERS

Fig. 221: Turn Signal Lamps / Hazard Warning Signal Flashers
Courtesy of VOLVO CARS CORPORATION

There are six lamps around the car to indicate direction changes. These are in the headlamps, tail lamps and on the side of the vehicle in front of the doors.

The turn signal lamps are operated using the left-hand control stalk.

To cancel the hazard warning signal flashers, where all the turn signal lights flash, press in the button for the hazard warning signal flasher. This is positioned in the middle of the dashboard by the center air vents.

The front and rear lamps are powered directly from the central electronic module (CEM).

A signal is also sent to the bulb in the hazard warning signal flasher switch when this function is activated.

The central electronic module (CEM) monitors the power consumption on each side to check for bulb faults. If the power consumption falls below a certain threshold value, a fault is indicated and the frequency of the signal to the bulbs is doubled on the side of the blown lamp.

There are diagnostics for the front and rear turn signal lamps.

HIGH LEVEL STOP LAMP

Fig. 222: High Level Stop Lamp
Courtesy of VOLVO CARS CORPORATION

COURTESY LIGHTING / KEY LIGHTING / GLOVE COMPARTMENT LIGHTING

Fig. 223: Courtesy Lighting / Key Lighting / Glove Compartment Lighting
Courtesy of VOLVO CARS CORPORATION

There are various lamps inside the passenger compartment, such as the courtesy lighting and glove compartment lighting for example. There are also LEDs around the keyhole in the ignition switch.

The lamps for the courtesy lighting are in the soundproofing panels on the driver and passenger sides. The lamp for the glove compartment is positioned on the left-hand inner side.

The lighting time can be programmed via the upper electronic module (UEM).

There are diagnostics for the key lighting and glove compartment lighting.

HORN

Fig. 224: Horn
Courtesy of VOLVO CARS CORPORATION

There are two horns in front of the radiator. There are four switches in the steering wheel. The horn is activated when one of these is closed.

The signal continues for as long as the switch is closed.

The horn is also activated when the panic alarm button on the remote control is pressed (certain markets).

The power supply for the horn is controlled from the central electronic module (CEM).

FUEL PUMP

Fig. 225: Fuel Level Sensor
Courtesy of VOLVO CARS CORPORATION

The fuel pump (FP) is located on the inside of the fuel tank on the right-hand side. The power supply for the pump is checked by the central electronic module (CEM) which operates a relay. This relay controls the power supply to the pump and is directly connected to the central electronic module (CEM).

The central electronic module (CEM) uses the controller area network (CAN) to communicate with the engine control module (ECM) which requests power to the pump system. The active-on-demand pump system that receives a control signal from the engine control module (ECM) to control the flow.

The central electronic module (CEM) also communicates with the supplemental restraint system (SRS) module via a directly connected signal. In the event of a collision, the supplemental restraint system module (SRS) transmits data and the central electronic module (CEM) closes the relay for the pump system and shuts off the power supply to the fuel pump (FP).

There are diagnostics for the input signal from the engine control module (ECM) and for the relay for the fuel pump (FP).

In the event of a fault in the controller area network (CAN) or central electronic module (CEM), there is a limp-home function in the central electronic module (CEM). This keeps the fuel pump (FP) relay active throughout the operating cycle.

This function is stopped in the event of a collision. A signal is transmitted from the supplemental restraint system module (SRS) to the central electronic module (CEM).

If there are electrical faults, the engine cannot be restarted after a collision.

FUEL LEVEL

Fig. 226: Locating Fuel Level Sensors
Courtesy of VOLVO CARS CORPORATION

The fuel level in the tank is measured by two sensors. The sensors are located on each side of the fuel tank. Cars with engine B5244S6 have only one sensor, on the pump side. The sensor is directly connected to the central electronic module (CEM).

There are different tables for different fuel tank sizes. The tables are stored in the central electronic module (CEM) and indicate which sensor values correspond to the remaining fuel in the tank. The central electronic module (CEM) determines which tank is in the car by reading a parameter.

The resistance of the sensor increases as the fuel volume in the tank decreases. The signals from the sensors are compared with the values in the fuel tank table to obtain a value for the remaining fuel volume. This data is displayed by the fuel gauge in the driver information module (DIM).

If the sensors are faulty, the fuel gauge will show 0.

There are diagnostics for the fuel level sensors.

The fuel level sensor for Bi-fuel is connected to the rear electronic module (REM).

WASHER / WIPERS

Fig. 227: Wiper Motors
Courtesy of VOLVO CARS CORPORATION

The windshield wipers are powered by a motor positioned under the cowl. There are also washer nozzles on the hood and bumper cover for cleaning the windshield and headlamps. The washer nozzles are connected to a pump motor on the windshield washer reservoir at the front right of the engine compartment.

For cars with five doors, there is a wiper and washer nozzle for the rear windshield.

The windshield wipers are operated using the right-hand control stalk. There are four positions:

- intermittent
- single sweep
- low speed
- high speed.

The time between strokes for intermittent wiping is adjusted using a ring on the control stalk.

Pull the control stalk towards the steering wheel to clean the windshield. The washer and wipers for the headlamps or high-pressure cleaning system are activated at the same time. The headlamp wipers operate for as long as washing is activated. They are not activated when only the windshield wipers are activated.

Push the control stalk away from the steering wheel to clean the rear windshield. There is a button at the end of the control stalk to control the rear wiper.

Information about the position of the control stalk is transmitted by the steering wheel module (SWM) to the central electronic module (CEM) using serial communication. The central electronic module (CEM) also receives a signal from the wiper motor if the wipers are in the park position.

The central electronic module (CEM) also monitors the windshield washer reservoir level via a level sensor in the reservoir. The switch in the level sensor closes if the level falls below one liter. A text message indicating that the windshield washer fluid needs to be topped up then lights in the driver information module (DIM) for approximately 10 seconds.

The power supply for the rear windshield wiper is via a directly connected relay in the rear electronic module (REM). The windshield wiper motor and high-pressure cleaning are supplied with power via relays in the engine compartment. The washer pump and headlamp wiper motors are powered via the central electronic module (CEM).

There are diagnostics for the windshield wiper motors and relays.

STARTER MOTOR

Fig. 228: Starter Motor
Courtesy of VOLVO CARS CORPORATION

The starter motor is on the left-hand side of the engine by the air cleaner (ACL) housing. The starter motor is powered directly from the battery. There is a solenoid on the starter motor to close the circuit. The central electronic module (CEM) activates a relay in the relay box in the engine compartment to act on the solenoid. This supplies the solenoid with power and closes the circuit for the starter motor.

The starter motor turns when the key is turned to position III in the ignition switch.

There are different functions which prevent starting, depending on whether the car has an automatic or manual transmission. The central electronic module (CEM) also has an electronic immobilizer function which communicates with a transponder in the key.

- Cars with manual transmissions have a sensor in the clutch pedal. The clutch pedal must be depressed to allow starting (certain markets)
- In cars with type 4T65EV automatic transmissions, a signal is transmitted from the gear-shift position sensor to the transmission control module (TCM) which then sends a directly connected signal to the central electronic module (CEM)
- In cars with AW automatic transmissions, a directly connected signal is transmitted directly from the gear-shift position sensor to the central electronic module (CEM).

There are diagnostics for the relay for the starter motor.

SPEED SENSITIVE POWER STEERING

Fig. 229: Power Steering Control Module
Courtesy of VOLVO CARS CORPORATION

If the car has speed dependent power steering to control the steering assistance, there is a solenoid which controls a hydraulic valve on the steering gear.

The solenoid is controlled by the power steering control module. This receives speed data from the directly connected speed signal from the central electronic module (CEM).

The power steering control module uses a signal to check the solenoid. The solenoid deploys the valve on the steering gear to the required degree and regulates the oil in the steering gear to reduce or increase the servo assistance. The steering assistance increases at lower speeds and is reduced at higher speeds.

There are no diagnostics for the power steering.

PARKING HEATER (OPTIONAL EXTRA)

Fig. 230: Climate Control Module
Courtesy of VOLVO CARS CORPORATION

The start time of the heater is programmed as follows:

- the desired parking function is selected by turning the ring on the control stalk
- the desired time is selected by turning the ring on the control stalk
- press the RESET button.

Direct start can also be used to start the heater.

The climate control module (CCM) is activated when the engine coolant temperature (ECT) is greater than +20 °C. The blower fan starts and distributes the air in the passenger compartment.

Certain conditions must be met before the heater can start. These are:

- Quantity of fuel greater than 4 liters
- No diagnostic trouble codes (DTCs) that will prevent starting are stored in the central electronic module (CEM)
- The airbags have not deployed.

When the conditions are met, the heater glow plug is activated for 1 minute. If the voltage has dropped below 11.5 V, the climate control module (CCM) is switched off. The heater and the climate control module (CCM) are stopped if the voltage falls below 11.3 V. A message indicating low battery voltage is displayed in the driver information module (DIM). These voltage values apply even if the heater is operating normally.

To minimize the risk of the fuel pump for the heater failing due to lack of use, the central electronic module (CEM) sends a signal every week to the combustion preheater module (CPM) to activate the pump for approximately 1 second. This takes place when the ignition is switched off.

Remote start of parking heater (Applies from and incl. structure week 201020)

With remote start of parking heater it is possible to set timers for the parking heater as well as direct start of the parking heater via a computer with internet connection or via mobile telephone. Only applies to vehicles with Phone module (PHM).

TWILIGHT SENSOR

Fig. 231: Sun Sensor
Courtesy of VOLVO CARS CORPORATION

The twilight sensor consists of a photo diode powered from the central electronic module (CEM). The conductivity of the diode depends on the amount of light to which it is exposed.

The diode is under a diffusing lens which reduces the sensitivity of the photo diode to the angle of the light hitting it. Increased light intensity reduces the voltage over the photo diode.

The control module measures the voltage across the photo diode and converts the voltage to information which is then transmitted to other control modules via the controller area network (CAN).

The twilight sensor is in the same holder as the sun sensor.

There are diagnostics for the twilight sensor.

SUN SENSOR (ELECTRONIC CLIMATE CONTROL ONLY)

Fig. 232: Sun Sensor
Courtesy of VOLVO CARS CORPORATION

The sun sensor consists of a photo diode powered from the central electronic module (CEM). The conductivity of the diode depends on the amount of light to which it is exposed.

The diode is located under a diffusing lens which reduces the sensitivity of the photo diode to the angle of the light hitting it. Increased sun intensity reduces the voltage over the photodiode.

The control module measures the voltage across the photo diode and converts the voltage to information which is then transmitted to the climate control module (CCM) via the controller area network (CAN).

The sun sensor is located in the middle of the dashboard by the windshield.

There are diagnostics for the sun sensor.

BLIND SPOT INFORMATION SYSTEM (BLIS)

Fig. 233: Locating Blind Spot Information System LED
Courtesy of VOLVO CARS CORPORATION

The blind spot information system (BLIS) is an auxiliary system designed to help the vehicle's driver when moving sideways. The blind spot information system (BLIS) consists of two cameras integrated in the external rear view mirrors and two LEDs located in the panel at the front of the inside of the respective windows.

The central electronic module (CEM) communicates with the left camera module (LCM) and the right camera module (RCM) via serial communication.

The blind spot information system (BLIS) is always activated automatically when the ignition is switched on, but it is possible to deactivate and activate the blind spot information system (BLIS) using one of the switches on the dashboard environment panel on the climate control module (CCM). A signal is then transmitted via the central electronic module (CEM) to the left camera module (LCM) and the right camera module (RCM) with a request to deactivate or activate the blind spot information system (BLIS).

When reverse gear is engaged, the blind spot information system (BLIS) is deactivated.

The blind spot information system (BLIS) can be diagnosed.

DIAGNOSTIC FUNCTIONS

GENERAL INFORMATION

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. The control module can store up to 10 diagnostic trouble codes (DTCs). A fault which is detected in the most recent operating cycle is defined as permanent. Other faults which are detected are defined as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N.

READING OFF EXTENDED DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION

This function can be used to read parameters, status identifiers and counters stored at the same time as a diagnostic trouble code (DTC). These are called frozen values.

For further information, see: **DESCRIPTION OF FROZEN VALUES, CENTRAL ELECTRONIC MODULE (CEM)**

READING OFF THE PARAMETER VALUES

Using this function, the status or value of parameters can be read off. The status/value is presented digitally.

For further information about the different parameters, see: **DESCRIPTION OF PARAMETERS**

ACTIVATING COMPONENTS AND FUNCTIONS

This function can be used to activate components and functions which affect the outputs of the central electronic module (CEM).

For further information, see: **DESCRIPTION OF ACTIVATIONS**

READING OFF AND PROGRAMMING DATA

This function allows programmed data to be read off or data such as customer parameters to be programmed in.

NOTE: **If possible, all data must be read out from the control module before replacement. After replacement the relevant data must be programmed into the new control module. The data must be read off before the control module is replaced. This is so that the same information can be programmed in to the new control module.**

PROGRAMMING KEYS

Add or Remove key

This function is used to add a new key or remove a non-functioning or lost key.

DESCRIPTION OF FROZEN VALUES, CENTRAL ELECTRONIC MODULE (CEM)

EXPLANATION

Not all the parameters described need to be implemented in the control module. This varies from system to system.

Frozen values are parameter values that are stored when a diagnostic trouble code (DTC) is stored.

BATTERY VOLTAGE, VALUE

Measurement range: 0-12 V.

Normal value when the generator (GEN) is charging: 13.0-14.5 V.

DISTANCE, VALUE

Measurement range: 0-1048575 km.

The value indicates the total mileage of the car at the time the diagnostic trouble code (DTC) was stored.

PASSENGER COMPARTMENT TEMPERATURE, VALUE

Measurement range: -60-195 °C.

The combined instrument panel obtains the value via the control area network (CAN).

OUTSIDE TEMPERATURE, VALUE

Measurement range: -128-127.75 °C.

The combined instrument panel obtains the value via the control area network (CAN).

ENGINE RUNNING, STATUS

The status displays whether the engine was running when the diagnostic trouble code (DTC) was stored.

No = the engine was not running

Yes = the engine was running

TIME, VALUE

The value displays the time that has passed since the diagnostic trouble code (DTC) was stored.

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the central electronic module (CEM). When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module. The PINs for the existing remote controls are downloaded at the same time.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

When installing a completely new central electronic module (CEM) in the vehicle, the PIN codes are downloaded into the control module (when downloading software) for the following:

- central electronic module (CEM)
- immobilizer
- transponder (key).

The PIN codes are downloaded automatically in the order procedure available in VIDA (Volvo scan tool). The PIN codes are retrieved from the Volvo central database and are sent in the software package when software is ordered for the new control module.

The central electronic module (CEM) is to the left of the steering column under the dashboard. The entire control module is removed from the car during replacement.

Because of the unique PIN codes, the central electronic module (CEM) cannot be moved between cars.

Five customer parameters (six for 5 door cars) can be programmed into the central electronic module (CEM). These customer parameters are stored in the control module but not in the Volvo central database. This means that the customer parameters must be reprogrammed when hardware is replaced.

The customer parameters which can be programmed are:

- **Automatic locking.** If this function is activated, the side doors lock when the speed exceeds 7 km/h (5 mph). Selectable values: On / off
    1. The tailgate wiper can only be activated manually
    2. The tailgate wiper can be activated automatically when back-up (reverse) gear is selected and the front wipers are activated.
- **Locking acknowledgment via the turn signal lamps.** If this function is activated, the turn signal lamps flash when the car is locked and unlocked. Selectable values: On / Off
    1. The tailgate wiper can only be activated manually
    2. The tailgate wiper can be activated automatically when back-up (reverse) gear is selected and the front wipers are activated.
- **Tailgate wiper (certain models).** The tailgate wiper function can be programmed in two ways:
    1. The tailgate wiper can only be activated manually
    2. The tailgate wiper can be activated automatically when back-up (reverse) gear is selected and the

front wipers are activated.

FUNCTION

GENERATOR (GEN) (ALTERNATOR CONTROL MODULE (ACM))

Fig. 234: Generator And Alternator Control Module
Courtesy of VOLVO CARS CORPORATION

CURRENT LIMITING

Fig. 235: CEM Communication Diagram

Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) (4/56) communicates with the alternator control module (ACM) (6/26) via LIN-communication. In this way the central electronic module (CEM) receives information about how much current the generator produces and how much current can be used for the various loads in the vehicle.

The central electronic module (CEM) uses the prevailing outside temperature to calculate the voltage at which the battery should be charged.

Under certain conditions the generator cannot produce enough current for those loads which are connected. The central electronic module (CEM) communicates with the climate control module (CCM) (3/112) which then completely or partially switches off the following loads:

- electrical additional heater
- rear demist
- electrically heated seats
- heated door mirrors.

The central electronic module (CEM) also transmits a request via the Control area network (CAN) to the engine control module (ECM) to increase the engine idle speed.

When the engine is not running all current is taken from the battery. There are a number of different loads which can be activated when the engine is not running, for example the infotainment system (XC90). The central electronic module (CEM) continuously monitors the voltage level of the battery. When the voltage level is too low the central electronic module (CEM) transmits information to the infotainment control module (ICM) (16/1) which then shuts off the infotainment system. In the event of a fault, the central electronic module (CEM) transmits data via the Control area network (CAN) to the driver information module (DIM) (5/1) which displays a text message to the user.

If the infotainment system used in key position II, when the engine is not running, the information is sent to the driver information module (DIM). A message is displayed if the infotainment system is switched off for 2 minutes.

CHARGE VOLTAGE

Fig. 236: Identifying Charge Voltage
Courtesy of VOLVO CARS CORPORATION

To charge the battery optimally the central electronic module (CEM) calculates the output voltage from the generator (GEN) using the temperature of the battery. The alternator control module (ACM) controls the output voltage, depending on the control from the central electronic module (CEM). See the illustration above. In some driving conditions for example, the engine control module (ECM) is able to affect generator (GEN) control, whereby the output voltage will deviate from the above.

TRIP COMPUTER AND DISPLAYING/ERASING TEXT MESSAGES

Fig. 237: Steering Wheel Module, Central Electronic Module And Driver Information Module Communication Diagram
Courtesy of VOLVO CARS CORPORATION

The left-hand control stalk is used to control the trip computer and to display and erase text messages in the driver information module (DIM) (5/1).

The steering wheel module (SWM) (3/254) transmits data to the central electronic module (CEM) using LIN communication to indicate the selected function. The central electronic module (CEM) (4/56) forwards this data to the driver information module (DIM) via the CAN network.

The trip computer menu is controlled using the ring on the left-hand control stalk. Turn the ring forwards or backwards to scroll through the menu one step at a time. Some menu selections, such as average speed and fuel consumption, can be reset using the RESET button.

Error messages displayed in the driver information module (DIM) display are erased using the READ button.

HEADLAMPS

Fig. 238: Headlamps Communication Diagram
Courtesy of VOLVO CARS CORPORATION

Depending on the position of the knob, the light switch module (LSM) (3/111) transmits information via serial communication to the central electronic module (CEM) to turn on low beam. The central electronic module (CEM) (4/56) then transmits a control signal to activate the low beam relay. The bulbs are then supplied with power.

To change to high beam, the left-hand control stalk is pulled towards the steering wheel. The serial communication signal from the steering wheel module (SWM) (3/254) is transmitted to the central electronic module (CEM) which activates the high beam relay and supplies power to the high beam. For Bi-Xenon lamps, the position of the reflector is also changed so that the Xenon lamp is on at high beam.

The central electronic module (CEM) also transmits a CAN signal to the driver information module (DIM) (5/1) to light the indicator lamp for high beam.

There is a Limp Home function which ensures that low beam still works if there is a fault in the control area network (CAN). For Bi-Xenon lamps the beam is then set to the shortest range.

HEADLAMP RANGE ADJUSTMENT (CERTAIN MARKETS)

Fig. 239: Headlamp Range Adjustment Communication Diagram
Courtesy of VOLVO CARS CORPORATION

Headlamp range adjustment is controlled by the central electronic module (CEM) (4/56). The central electronic module (CEM) communicates with the light switch module (LSM) (3/111) using serial communication.

If the thumb wheel in the light switch module (LSM) is turned, information about the position of the wheel is transmitted to the central electronic module (CEM). The central electronic module (CEM) transmits a pulse width modulation (PWM) signal to the actuator motors (6/38-39) with the pulse ratio set according to the position of the thumb wheel. The headlamp range can be adjusted in 16 stages.

AUTOMATIC RANGE ADJUSTMENT (BI-XENON)

Fig. 240: Automatic Range Adjustment Communication Diagram
Courtesy of VOLVO CARS CORPORATION

Automatic headlamp range adjustment is controlled by the central electronic module (CEM) (4/56). The position sensor (7/120) on the rear suspension transmits signals to the rear electronic module (REM) (4/58) about the angle of the car in terms of the load conditions.

The rear electronic module (REM) transmits this data via the control area network (CAN) to the central electronic module (CEM) which compares the information with the table for the relevant model. The table is stored in the central electronic module (CEM).

The actuator motors (6/38-39) are then operated from the central electronic module (CEM) via a PWM signal, the pulse ratio of which depends on the angle the lamps need to be set to.

FRONT FOG LAMPS

Fig. 241: Front Fog Lamps Communication Diagram
Courtesy of VOLVO CARS CORPORATION

The front fog lamps (10/5-6) are activated by pressing the button for the front fog lamps in the light switch module (LSM) (3/111). The light switch module (LSM) transmits data to the central electronic module (CEM) (4/56) to light the lamps. The central electronic module (CEM) activates the relay and the bulbs are supplied with power via the relay.

FRONT PARKING LAMPS

Fig. 242: Front Parking Lamps Communication Diagram
Courtesy of VOLVO CARS CORPORATION

Parking lamps (10/11-12) light when:

- the knob in the light switch module (LSM) (3/111) is in the low beam position
- the knob in the light switch module (LSM) is in the parking lamp position
- low beam is lit via the low beam automatic function.

The lamp switch module (LSM) transmits data using serial communication to the central electronic module (CEM) (4/56) to activate the lamps.

The lamps are supplied with power via a relay which is activated by the central electronic module (CEM). The front parking lamps have a direct power supply.

The rear parking lamps and license plate lighting are powered by the rear electronic module (REM).

There is a Limp Home function for the parking lamps so that they will work even if there is a fault in the control area network (CAN) or in the serial communication between the light switch module (LSM) and the central electronic module (CEM).

TURN SIGNAL LAMPS / HAZARD WARNING SIGNAL FLASHERS

Fig. 243: Turn Signal Lamps / Hazard Warning Signal Flashers Communication Diagram
Courtesy of VOLVO CARS CORPORATION

This function is controlled by the left control stalk. The steering wheel module (SWM) (3/254) sends data to the central electronic module (CEM) (4/56) to activate the turn signal lamps via serial communication. The central electronic module (CEM) transmits information to the driver information module (DIM) (5/1) to activate the turn signal indicator and powers the turn signal lamp.

The power supply is pulsed and the turn signal lamps are activated 90 times per minute.

The hazard warning signal flasher is activated by closing the switch (3/6) and transmits a signal to the central electronic module (CEM) to start the function. The central electronic module (CEM) transmits a signal in the same way as above, but to both sides. The central electronic module (CEM) also transmits a signal to the bulb in the switch to indicate that the hazard warning signal flashers are on. If the ignition key is in position I or II,

there is a clicking sound from the driver information module (DIM). If the ignition is switched off, there is no sound, but the hazard warning signal flashers continue to flash.

If a fault occurs with a lamp, the central electronic module (CEM) detects the reduction in power consumption and the frequency is doubled on the side where the fault occurred.

HIGH LEVEL STOP LAMP

Fig. 244: High Level Stop Lamp Communication Diagram
Courtesy of VOLVO CARS CORPORATION

COURTESY LIGHTING / KEY LIGHTING / GLOVE COMPARTMENT LIGHTING

Fig. 245: Courtesy Lighting / Key Lighting / Glove Compartment Lighting Communication Diagram
Courtesy of VOLVO CARS CORPORATION

The courtesy lighting (10/125-126), ignition switch (16/65) and glove compartment lighting (10/29) are controlled via the central electronic module (CEM) (4/56). All other interior lighting is controlled by the upper electronic module (UEM) (4/70). The central electronic module (CEM) powers the lamps which it controls directly.

The lamps are powered if a door is opened (3/74-77), or when the upper electronic module (UEM) transmits a request via the control area network (CAN). The upper electronic module (UEM) transmits a request when it has received an unlock command from one of the remote controls. If a door is opened, the central electronic module (CEM) sends a control area network (CAN) signal to the upper electronic module (UEM) to light the lighting it controls.

The glove compartment lighting (10/29) is supplied with power directly from the central electronic module (CEM) when the switch by the lamp is activated when the glove compartment is opened.

HORN

Fig. 246: Horn Communication Diagram
Courtesy of VOLVO CARS CORPORATION

The horn is operated when the steering wheel module (SWM) (3/254) receives a signal from the switches (3/37) in the steering wheel. The steering wheel module (SWM) sends data to the central electronic module (CEM) (4/56) via serial communication indicating that the switch is closed. The central electronic module (CEM) activates the relay for power supply to the horn.

There is also a signal directly connected from the steering wheel module (SWM) to the central electronic module (CEM). This is a Limp-Home function.

FUEL PUMP

Fig. 247: Fuel Pump Communication Diagram
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) (4/56) receives a request from the engine control module (ECM) (4/46) via the control area network (CAN) to start the fuel pump (FP) (6/33). The central electronic module (CEM) then activates the relay which supplies the fuel pump with power.

In the event of a collision in which the airbags are deployed, a signal is transmitted from the supplemental restraint system (SRS) module (4/9) to the central electronic module (CEM) which deactivates the relay for the fuel pump.

FUEL LEVEL

Fig. 248: Fuel Level Communication Diagram
Courtesy of VOLVO CARS CORPORATION

The fuel level is gauged by the fuel level sensors (7/130, 7/143). The signals from the sensors are transmitted to the central electronic module (CEM) (4/56). The central electronic module (CEM) calculates the remaining quantity of fuel by comparing the signals with a tank table stored internally. Information about the quantity of fuel is transmitted via the Control area network (CAN) to the driver information module (DIM) (5/1), where the

fuel level is displayed on the fuel gauge.

WIPERS / WASHERS

Fig. 249: Wipers / Washers Communication Diagram
Courtesy of VOLVO CARS CORPORATION

The right-hand control stalk is moved downwards through three positions to operate the windshield wipers. The steering wheel module (SWM) (3/254) transmits information to the central electronic module (CEM) (4/56) about the selected position using serial communication. The central electronic module (CEM) then activates the relay which supplies the wiper motor (6/1) with power in position 1. If high speed wiping is selected, the relay is also activated to power the motor in position 2.

The central electronic module (CEM) receives a signal from the motor when the wipers are in the parked position so that the wipers can be stopped in the correct position.

For intermittent wiping, the process is the same as for low speed, but the time between each stroke is set using the ring on the control stalk to one of eight positions between 1 and 27 seconds. The central electronic module (CEM) controls this once it has received information about intermittent wiping from the steering wheel module (SWM) via serial communication.

The windshield and headlamps are washed when the right-hand control stalk is moved towards the steering wheel. The steering wheel module (SWM) transmits information to the central electronic module (CEM) to activate washing via serial communication. The central electronic module (CEM) activates an internal relay

which powers the pump motor (6/127).

For other models, the central electronic module (CEM) activates the relay (2/182) which powers high-pressure cleaning (6/104).

The central electronic module (CEM) receives a signal from the level sensor (7/5) in the windshield washer reservoir so that it can check the windshield washer reservoir level. The switch in the level sensor closes if the level falls below one liter. The central electronic module (CEM) sends the signal to Driver information module (DIM) (5/1) via the controller area network (CAN). The driver information module (DIM) displays a text message for approximately 10 seconds indicating that the windshield washer fluid needs to be topped up.

The tailgate wiper (6/32) is controlled by the rear electronic module (REM) (4/58). The rear electronic module (REM) receives a signal from the steering wheel module (SWM) via the central electronic module (CEM). The rear electronic module (REM) then powers the relay to start the tailgate wiper. The tailgate wiper is powered by the rear electronic module (REM).

The tailgate wiper can be programmed so that it is not activated if the windshield wipers are on and back-up (reverse) gear is selected.

Rear windshield cleaning is activated when the right-hand control stalk is pushed away from the steering wheel. The steering wheel module (SWM) transmits information to the central electronic module (CEM) to activate tailgate washing via serial communication. The central electronic module (CEM) activates the relay to power the pump motor (6/127). At the same time the rear electronic module (REM) activates the tailgate wiper.

The wipers only operate at low speed if there is a fault in the control area network (CAN). If this is the case, the central electronic module (CEM) receives a directly connected signal from the steering wheel module (SWM).

There is no Limp Home function for the rear windshield washer and wiper.

STARTER MOTOR

Fig. 250: Starter Motor Communication Diagram
Courtesy of VOLVO CARS CORPORATION

Manual transmissions

The starter motor (6/25) is operated by turning the key in the ignition switch (3/1) to position III.

- For transmissions **with** a clutch interlock (certain markets), a signal is transmitted from the ignition switch to the engine control module (ECM) (4/46). The engine control module (ECM) detects the position of the clutch pedal sensor (7/123). The engine control module (ECM) transmits data to the central electronic module (CEM) (4/56) via the control area network (CAN) about the position of the pedal. The central electronic module (CEM) requires a signal that the clutch is pressed down and that the key is in position III before it will send a signal to the relay (2/35). When the relay is activated, the solenoid in the starter motor is powered
- For transmissions **without** clutch interlock, the central electronic module (CEM) (4/56) activates relay 2/35 and powers the solenoid in the starter motor (6/25).

The starter motor turns for as long as the key is in position III. If the engine has been started once, there is a Limp Home function so that the engine can be started again even if there is a fault in the control area network (CAN). This function is active for a brief period after the key is removed from the ignition switch. After this time the car will not start because there is no communication for the immobilizer between the central electronic module (CEM) and the engine control module (ECM).

Automatic transmission

The starter motor (6/25) is operated by turning the key in the ignition switch (3/1) to position III.

- For transmission 4T65EV, a signal is transmitted from the gear-shift position sensor (3/71) via the transmission control module (TCM) (4/28) to the central electronic module (CEM) (4/56) indicating that the gear selector is in position P/N
- For AW transmissions the signal is transmitted directly from the gear-shift position sensor to the central electronic module (CEM). The central electronic module (CEM) requires this signal and a signal indicating that the key is in position III before it will send a signal to the relay (2/35). When the relay is activated, the solenoid in the starter motor is powered.

The starter motor turns for as long as the key is in position III. If the engine has been started once, there is a Limp Home function so that the engine can be started again even if there is a fault in the control area network (CAN). This function is active for a brief period after the key is removed from the ignition switch. After this time the car will not start because there is no communication for the immobilizer between the central electronic module (CEM) and the engine control module (ECM).

SPEED SENSITIVE POWER STEERING

Fig. 251: Speed Sensitive Power Steering Communication Diagram
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) (4/56) receives information that the engine is running from the engine control module (ECM) (4/46) on the controller area network (CAN). It receives information about vehicle speed from the brake control module (BCM) (4/16). The central electronic module (CEM) then controls the power steering control module which in turn acts on the solenoid.

The central electronic module (CEM) checks the signals. If a fault is detected, the servo assistance is set to normal (approximately 70 km/h) and the system is disengaged. The central electronic module (CEM) also transmits a signal to the driver information module (DIM) (5/1) via the control area network (CAN) which lights the general warning lamp and displays a text message.

DESCRIPTION OF FUNCTION OF THE OPERATING STATUS OF THE HEATER

The heater can have a number of different statuses. Each status and what should occur in it is described below.

Operating status:	Description:
0: The heater has not started	Initialization of the combustion preheater module (CPM).
1: The heater starts	Heater self test. The glow plug and the water pump are activated. The combustion fan then starts at low speed to ventilate the heater. This is to cool the glow plug so that the flame sensor does not detect light from the glow plug as a flame. The control module pulses the supply to the glow plug (pulse width modulation (PWM) signal). The glow plug is sufficiently warm to ignite the fuel after approximately 45 seconds. This whole process takes approximately 1 minute.
2: The heater starts and the fuel pump is active	The fuel pump starts and the speed of the combustion fan increases. The control module waits for a flame. The blower fan will now be running. Maximum time 1 minute.
3: The heater runs	A flame has been detected by the flame sensor and heats the heater. When the car is being driven the heater is stopped if the engine coolant temperature (ECT) exceeds a certain level. The heater is stopped by cutting the fuel supply. The combustion fan ventilates the heater when the flame has gone out. When the temperature falls below a certain level, the heater starts again. This means that the heater cycles between 2 temperature ranges.
4: The heater stops	The fuel pump stops, the flame is extinguished and the heater is ventilated.
5: The heater waits	Waiting for the engine coolant temperature (ECT) to fall low enough for the heater to start again.
6: The heater has stopped	The heater only has this status if a fault has occurred.
7: The flame is extinguished	The flame has gone out while the car is being driven.
8: Residual heat	If, when the outside temperature is low, the driver is in the car and turns on the heater, the water pump starts in order to heat the passenger compartment.
9: Fuel pump activated	Used in production.
10: Activating the fuel pump	Single pulses to the fuel pump are used to prevent the fuel pump sticking.

The vehicle configuration can be read off to check what functions the car is equipped with. The following affect the function of the heater:

- Parking and additional heater function
- Parking heater or not (gasoline engines)
- Residual heater or not
- Electrical engine block heater (time controlled via the driver information module (DIM)) or not.

FUEL DRIVEN PARKING HEATER

Fig. 252: Additional Heater And Parking Heater Communication Diagram
Courtesy of VOLVO CARS CORPORATION

The driver sets the desired departure time using one of the two timer functions in the display on the driver information module (DIM) (5/1). The time is programmed by twisting the ring on the control stalk and by pressing the "reset" button for the desired time (timer 1, timer 2 or direct start). Direct start can also be used to start the heater.

The central electronic module (CEM) (4/56) receives data about when the driver wants to drive from the control stalk module (steering wheel module (SWM)) (3/254) and the driver information module (DIM).

The central electronic module (CEM) calculates when the heater needs to start so that it is warm enough in relation to the outside temperature. Information about temperature is obtained from the outside temperature sensor in the right-hand door mirror. This sensor is connected to the driver door module (DDM) or passenger door module (PDM).

The central electronic module (CEM) calculates when the heater needs to start:

- The heater calculates when start is required (15-50 minutes before the intended departure at medium low temperatures between -10 °C and +15 °C)
- This procedure takes a maximum of one minute. 60 minutes at temperatures below -10 °C
- This running time of the heater is a minimum of 15 minutes before the planned departure. (Warm temperatures between +15 °C and +25 °C).

When the heater is started directly using the control stalk it runs until it is shut off or for a maximum of 60 minutes. The heater is on for 10 minutes after the set time to allow for the driver getting to the car late.

A text message is displayed in the driver information module (DIM) when the heater is running.

Remote start of parking heater (Applies from and incl. structure week 201020)

With remote start of parking heater it is possible to set timers for the parking heater as well as direct start of the parking heater via a computer with internet connection or via mobile telephone. Only applies to vehicles with Phone module (PHM).

ELECTRICAL HEATER WITH TIMER FUNCTION

Fig. 253: Electrical Heater With Timer Function Communication Diagram
Courtesy of VOLVO CARS CORPORATION

The desired departure time is set using the steering wheel module (SWM) (3/254).

The central electronic module (CEM) (4/56) calculates when the heater needs to start. The heater starts 2 hours and 45 minutes before the set departure time, irrespective of the temperature. A text message is displayed in the driver information module (DIM) (5/1) when the electrical heater is running.

The accessory electronic module (AEM) (4/78) electrically controls when the heater should be switched on and off. The engine block heater must be connected to a wall socket. The accessory electronic module (AEM) activates a relay which closes the switch for a heater element.

RESIDUAL HEATER

Fig. 254: Residual Heater Communication Diagram
Courtesy of VOLVO CARS CORPORATION

This function can be ordered as an accessory.

The function is activated in the driver information module (DIM) (5/1) using the control stalk (compare to the parking heater). Information about activation is sent to the central electronic module (CEM) (4/56) and climate control module (CCM) (3/112). The blower fan and damper settings are set by the climate control module (CCM). The central electronic module (CEM) transmits data to the combustion preheater module (CPM) (4/7) instructing it to activate the water pump.

When the residual heater is activated it will operate as long as the coolant temperature is above 30 °C or for a maximum of 20 minutes or until the function is switched off.

This function is used when the coolant is already warm. The coolant pump is started thereby circulating the coolant. The heat is distributed from the coolant to the passenger compartment unit in the climate control unit and on to the passenger compartment.

When the residual heater is running, the passenger compartment is heated by the climate control module (CCM) controlling the fan and damper according to a customer parameter (Applies only to electronic climate control (ECC)). This parameter is used to set the distribution between the defroster and the floor. The normal setting is 30% defroster and 70% floor.

STARTING THE HEATER REMOTELY

Fig. 255: Starting The Heater Remotely Communication Diagram
Courtesy of VOLVO CARS CORPORATION

Cars with an accessory electronic module (AEM) (4/78) can have a remote start function for the heater. This allows the heater to be started using a pager. A stop or start signal is transmitted from the accessory electronic module (AEM) to the central electronic module (CEM) (4/56) to start or stop the heater (4/7). This function is available for both fuel driven and electrical heaters.

BLIND SPOT INFORMATION SYSTEM (BLIS)

Fig. 256: Blind Spot Information System Communication Diagram
Courtesy of VOLVO CARS CORPORATION

The cameras take 30 images a second and compare each image with the previous one to check whether any changes have taken place. To be able to determine whether a change is of any significance when moving sideways, the camera module also has to know the vehicle's speed. To calculate the vehicle's speed and know whether the vehicle is turning, the speed signals for the respective rear wheels from the brake control module (BCM) are used. The central electronic module (CEM) (4/56) receives information from the brake control module (BCM) (4/16) via the CAN network on the respective speeds of the two rear wheels. These two signals are then passed on to the left camera module (LCM) and right camera module (RCM) respectively via serial

communication.

If the camera module discovers that there is something in the dead angle, an orange LED, located on the inside of the panel at the front of the window on the door, comes on. This LED is directly connected to the respective camera module.

The blind spot information system (BLIS) can be deactivated using one of the switches on the dashboard environment panel. When this switch is depressed, a signal is transmitted from the climate control module (CCM) to the central electronic module (CEM) via the CAN network. The system is then deactivated until the switch is depressed again or the next time the vehicle is started.

If a fault is detected by the central electronic module (CEM), a diagnostic trouble code (DTC) is stored and a signal is transmitted via the CAN network to the driver information module (DIM), which turns on a general warning lamp and displays a text message.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 257: CEM
Courtesy of VOLVO CARS CORPORATION

The role of the central electronic module (CEM) is to control the controller area network (CAN) and to act as a bridge between the low and high speed sections of the controller area network (CAN) and the data link connector (DLC).

It also manages the following functions:

- Alarm (certain functions)
- Locks (certain functions)
- Immobilizer
- Headlamps
- Front parking lamps
- Front fog lamps

- Headlamp range adjustment (certain markets)
- Automatic range adjustment (Bi-Xenon)
- Turn signal lamps
- Courtesy lighting / key lighting / glove compartment lighting
- Fuel pump
- Wiper / washers for the windshield and headlamps
- Starter motor
- Speed sensitive power steering
- Horn
- Clock
- Power supply (generator control)
- Current limiting
- Fuel level display
- Additional heater.
- Parking heater
- Blind spot information system (BLIS)

The control module is to the left of the steering column under the dashboard. The entire control module is removed from the car during replacement.

A car configuration file is stored in the central electronic module (CEM). This file contains information about:

- the VIN of the car
- the structure week
- the equipment level of the car.

When replacing the central electronic module (CEM), the VIN cannot be read off until the software has been downloaded from the Volvo central database.

The central electronic module (CEM) communicates with directly connected components and with other control modules and components via serial communication and the control area network (CAN).

The central electronic module (CEM) uses built in diagnostics to check all activations and the input and output signals. A diagnostic trouble code (DTC) is stored if the control module detects a fault. In certain cases, the incorrect signal is replaced with a substitute value. Other control modules use the network to report to the central electronic module (CEM) if they have diagnostic trouble codes (DTCs) stored. This function is used when reading off diagnostic trouble codes (DTCs) without VIDA (Volvo scan tool).

Any diagnostic trouble codes (DTCs) are stored in the control module memory. This information can be read off using VIDA via the data link connector in the vehicle.

The easiest way to check if the central electronic module (CEM) is grounded and receiving power is to activate the hazard warning signal flasher. The central electronic module (CEM) is powered if the function operates.

SIGNALS

The table below summarizes the input signals to and output signals from the central electronic module (CEM). The signal types are divided into directly connected signals, serial communication and controller area network (CAN) communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: • Back-up (reversing) lamp switch (3/10) • Windshield wiper motor (6/1) • Windshield washer level sensor (7/5) • Horn switch (3/37) • Stop lamp switch (3/9) • Control signal P/N position, gear selector module (GSM) (3/156) (automatic transmissions only) • Supplemental restraint system module (SRS) (Airbag OK) (4/9) • Gear-shift position sensor (8/37) • Antenna ring, immobilizer (16/65) • Hazard warning signal flasher switch (3/6) • Fuel level sensor (7/130, 7/143) • Seat position sensor driver (3/255-256) (XC90 USA/CDN only) • Twilight sensor (7/12) • Sun sensor (7/12).	**Directly connected:** • Starter motor (6/25) • Headlamp range adjustment (6/38-39) (certain markets) • Windshield wiper (6/1) • Washer motor (6/127) • Horn (16/10-11) • Stop lamps via the rear electronic module (REM) (4/58) • Fuel pump (FP) (6/33) • Hazard warning signal flasher switch (3/6) • Glove compartment lighting (10/29) • Ignition switch lighting (16/65) • Courtesy lighting (10/125-126) • 12 V socket (9/25) • Auxiliary lamps (10/65, 10/66) • High beam (10/64, 10/68) • Low beam (10/66, 10/70) • Front parking lamps (10/11-12) • Turn signal lamps (10/13-14, 10/15-16, 10/47, 10/54) • Front fog lamps (10/5-6) • Electrical power steering module (EPS) (4/99).
Via serial communication: • Combustion preheater module (CPM) (4/7) (optional extra) • Light switch module (LSM) (3/111) • Steering wheel module (SWM) (3/254) • Alternator control module (ACM) (6/26). • Blind spot information system (BLIS) (6/62, 6/63) (optional extra)	**Via serial communication:** • Combustion preheater module (CPM) (4/7) (optional extra) • Light switch module (LSM) (3/111) • Steering wheel module (SWM) (3/254) • Alternator control module (ACM) (6/26). • Blind spot information system (BLIS) (6/62, 6/63) (optional extra)

Via Controller Area Network (CAN) communication: • Accessory electronic module (AEM) (optional equipment) (4/78) • Audio module (AUM) (16/1) (not XC90) • Brake control module (BCM) (4/16) • Climate Control Module (CCM) (3/112) • Driver door module (DDM) (3/126) • Differential electronic module (DEM) (optional equipment) (4/82) • Driver information module (DIM) (5/1) • Engine control module (ECM) (4/46) • Electronic throttle module (ETM) (4/50) • Passenger door module (PDM) (3/127) • Phone module (PHM) (optional equipment) (16/60) • Power seat module (PSM) (4/52) • Rear electronic module (REM) (4/58) • Road traffic information module (RTI) (16/45) (optional equipment, not XC90) • Steering wheel angle sensor module (SAS) (3/254) • Supplemental Restraint System Module (SRS) (4/9) • Transmission Control Module (TCM) (4/28) • Upper electronic module (UEM) (4/70) • Suspension module (SUM) (4/84) (optional extra) • Infotainment control module (ICM) (16/94) (XC90 only) • Data link connector (DLC) (17/13).	**Via Controller Area Network (CAN) communication:** • Accessory electronic module (AEM) (optional equipment) (4/78) • Audio module (AUM) (16/1) (not XC90) • Brake control module (BCM) (4/16) • Climate Control Module (CCM) (3/112) • Driver door module (DDM) (3/126) • Differential electronic module (DEM) (optional equipment) (4/82) • Driver information module (DIM) (5/1) • Engine control module (ECM) (4/46) • Electronic throttle module (ETM) (4/50) • Passenger door module (PDM) (3/127) • Phone module (PHM) (optional equipment) (16/60) • Power seat module (PSM) (4/52) • Rear electronic module (REM) (4/58) • Road traffic information module (RTI) (16/45) (optional equipment, not XC90) • Steering wheel angle sensor module (SAS) (3/254) • Supplemental Restraint System Module (SRS) (4/9) • Transmission Control Module (TCM) (4/28) • Upper electronic module (UEM) (4/70) • Suspension module (SUM) (4/84) (optional extra) • Infotainment control module (ICM) (16/94) (XC90 only) • Data link connector (DLC) (17/13).

CENTRAL LOCKING (2003-2004)

SIGNALS

The table below summarizes the input signals to and output signals from the different control modules for the lock function. The signal types are divided into directly connected signals, serial communication and control area network (CAN) communication.

Directly connected input signals from the sensors / switches to the control module:	Directly connected output signals to the controlled components / functions from the control module:
Brake control module (BCM) / ABS control module , (4/16) • Vehicle speed sensors (VSS) from all wheels, vehicle speed signal.	**Central electronic module (CEM)** (4/56) • All turn signal lamps, on/off • Shift relay deadlock/power child lock in rear doors.
Central electronic module (CEM) (4/56) • All doors, closed/open • Rear doors, locked/unlocked • Tailgate, closed / open • Collision output signal from SRS (supplemental restraint system) control module, collision/no collision.	**The driver's door module** (3/126) • Driver's door lock motor, lock/unlock • Lock motor deadlocked, lock/unlock.
The climate control module (3/112) • Switch for reduced alarm, on/off • Switch child lock, on/off • Switch valet lock, on/off.	**The passenger door module** (3/127) • Passenger door lock motor, lock/unlock • Lock motor deadlocked, lock/unlock.
The driver's door module (3/126) • Driver's door, locked/unlocked • Key, locking / unlocking.	**Rear electronic module** (4/58) • Rear doors lock motors, lock/unlock • Lock motor deadlocked, lock/unlock • Power child lock motors, lock/unlock • Fuel tank filler cover lock motor, lock/unlock
The passenger door module (3/127) • The passenger door, locked/unlocked.	**SRS control module** (4/9) • Collision output signal to the central electronic module, collision/no collision.
Rear electronic module (4/58) • Switch in the trunk lid, on/off (S60/S80 only).	

Received information to control modules via Controller Area Network (CAN):	Transmitted information to control modules via Controller Area Network (CAN):
The central electronic module (4/56) receives from: The brake control module (ABS-control module) (4/16) • Speed, speed signal. The climate control module (3/112) • Switch for reduced alarm, on/off • Switch child lock, on/off • Switch valet lock, on/off. Driver's door module (DDM) (3/126) • Driver's door, locked/unlocked • Key, locking / unlocking • Switch door panel, on/off. Passenger door module (3/127) • Passenger door, locked/unlocked • Switch door panel, on/off. Rear electronic module (4/58) Upper electronic module (4/70) • Remote control signal. LOCK, UNLOCK and TRUNK.	**The central electronic module (4/56) transmits to:** The driver information module (5/1) • Text message, reduced alarm, valet lock, child lock and fuel tank filler cover unlocked (only cars with switch for fuel tank filler cover opening). Driver's door module (DDM) (3/126) • Driver's door lock motor, lock/unlock • Lock motor deadlocked, lock/unlock. Passenger door module (3/127) • Passenger door lock motor, lock/unlock • Lock motor deadlocked, lock/unlock. Rear electronic module (4/58) • Rear doors lock motors, lock/unlock • Lock motor deadlocked, lock/unlock • Power child lock motors, lock/unlock • Fuel tank filler cover lock motor, lock/unlock
Driver information module (3/126) receives from: The central electronic module (CEM) (4/56) • Driver's door lock motor, lock/unlock • Lock motor deadlocked, lock/unlock.	**The brake control module (ABS-control module) (4/16) transmits to:** The central electronic module (CEM) (4/56) • Speed, speed signal.
Driver information module (5/1) receives from: The central electronic module (CEM) (4/56) • Text message, reduced alarm, valet lock, child	**Driver's door module (DDM) (3/126) transmits to:** The central electronic module (CEM) (4/56)

lock and fuel tank filler cover unlocked (only cars with switch for fuel tank filler cover opening).	• Driver's door, locked/unlocked • Key, locking / unlocking • Door panel switch, active/not active.
Passenger door module (3/126) receives from: The central electronic module (CEM) (4/56) • Passenger door lock motor, lock/unlock • Lock motor deadlocked, lock/unlock.	**The passenger door module (3/126) transmits to:** The central electronic module (CEM) (4/56) • Passenger door, locked/unlocked • Door panel switch, active/not active.
The rear electronic module (4/58) receives from: The central electronic module (CEM) (4/56) • Rear doors lock motors, lock/unlock • Lock motor deadlocked, lock/unlock • Power child lock motors, lock/unlock • Fuel tank filler cover lock motor, lock/unlock	**Rear electronic module (4/58) transmits to:** The central electronic module (CEM) (4/56)
	The upper electronic module (4/70) transmits to: The central electronic module (CEM) (4/56) • Remote control signal, LOCK, UNLOCK and BOOT.

SYSTEM DESCRIPTION

GENERAL INFORMATION

Fig. 260: Central Locking Input And Output Signals
Courtesy of VOLVO CARS CORPORATION

The lock function is a distributed function and uses a number of control modules for its function.

The control modules used for the lock function are:

- Central electronic module
- The brake control module, 2002-/ ABS-control module, 1999-2001
- Climate control module
- Driver's door module
- Driver information module
- Passenger door module
- Rear electronic module
- SRS (supplemental restraint system) control module
- Upper electronic module.

CENTRAL ELECTRONIC MODULE

The central electronic module (4/56) is the main control module for central locking functionality. The central electronic module determines how the lock should be locked and unlocked by receiving information on the Controller Area Network (CAN) from other control modules and via the directly connected signal cables from the components.

Signal cables are directly connected to the central electronic module from:

- Lock units in all doors (3/74-77), open / closed
- Lock units in the rear doors (3/76-77), locked / unlocked
- Lock unit tailgate (3/78), open/closed
- SRS (supplemental restraint system) control module (SRS) (4/9), collision/no collision.

The central electronic module is controlled via a direct cable:

- All turn signal lamps, on/off
- Shift relay for power child locks in the rear door, on/off. The shift relay is only installed on those cars equipped with power child locks. The relay shifts between child proof and deadlock positions. The shift between child proof and deadlock occurs by the central electronic module transmitting a signal to the relay, which shifts the relay to the directly connected cable. When the relay has shifted, a control signal is transmitted to the lock motor from the rear electronic module and the lock unit assumes the deadlock or childproof mode depending what the relay shifted to. To ensure that the relay shifts and that the lock unit has time to assume the new status, a control signal is transmitted from the central electronic module for approximately one second.

BRAKE CONTROL MODULE / ABS CONTROL MODULE

The brake control module (4/16), (ABS up to and including model year 2001) transmits information about the vehicle speed to the central electronic module via the Controller area network (CAN). The information is used for models with fuel tank filler cover locking via remote switch. The information is also used to prevent unlocking of the trunk using the remote control and automatic locking of the car.

Signal cables are directly connected to the brake control module (ABS) from:

- Vehicle speed sensors (VSS) from all wheels.

CLIMATE CONTROL MODULE

Climate control module (3/112) transmits information via the Controller area network (CAN) to the central electronic module about the status of the switch for reduced alarm, valet locking and child locks.

Signal cables are directly connected to the climate control module from:

- Switch for reduced alarm (3/174), on/off
- Switch for valet locking (3/173), on/off
- Switch for child lock (3/73), on/off.

DRIVER'S DOOR MODULE

The driver's door module (3/126) transmits information to the central electronic module via Controller area network (CAN), about whether the driver's door lock is lock or unlocked and the status of the switches in the driver's door. The central electronic module transmits information via the controller area network (CAN) to the driver's door module to activate the lock motor in the driver's door.

Signal cables are directly connected to the driver's door module from:

- Lock units in the driver's doors (3/74), locked / unlocked
- Key, locking / unlocking.

The driver's door module controls via direct cables:

- Driver's door lock motor, lock/unlock
- Lock motor deadlocked, lock/unlock.

DRIVER INFORMATION MODULE

Driver information module (5/1) displays a text message in the display. The information comes from the central electronic module via the controller area network (CAN). The text messages given are information about the reduced alarm, valet locking and child locks.

PASSENGER DOOR MODULE

The passenger door module (3/127) transmits information to the central electronic module via Controller area network (CAN), about whether the passenger door lock is lock or unlocked and the status of the switches in the passenger door. The central electronic module transmits information via the controller area network (CAN) to the passenger door module to activate the lock motor in the passenger door.

Signal cables are directly connected to the passenger door module from:

- Lock unit passenger door, locked/unlocked.

The passenger door module controls via direct cables:

- Passenger door lock motor, lock/unlock
- Lock motor deadlocked, lock/unlock.

REAR ELECTRONIC MODULE

The central electronic module transmits information via the controller area network to the rear electronic module to:

- activate the lock motors in the rear doors
- activate the lock motor for the fuel tank filler cover

Signal cables are directly connected to the rear electronic module from:

- Trunk lid switch, activated/not activated (sedan models only).

The rear control module controls via direct cables:

- Rear doors lock motors, lock/unlock
- Lock motors deadlocked, lock/unlock
- Power child lock motors, lock/unlock. The same relays in the rear electrical module as in the deadlocked lock motor are used for the power child lock. The shift between the motor for deadlocks and the power child lock motor occurs via direct cable from the central electronic module to a shift relay in the rear doors. For the power child lock the central electronic module transmits a control signal to the shift relay. At the same time the rear electronic module transmits a control signal to the lock motor
- Fuel tank filler cover lock motor, lock/unlock

SRS (SUPPLEMENTAL RESTRAINT SYSTEM) CONTROL MODULE

The SRS (supplemental restraint system) control module (4/9) transmits information about collisions to the central electronic module via a directly connected cable.

Signal cables are directly connected to the SRS (supplemental restraint system) from:

- Collision sensor, collision/no collision.

Signal cables are directly connected to the SRS (supplemental restraint system) from:

- Collision output signal to the central electronic module.

UPPER ELECTRONIC MODULE

The upper electronic module (4/70) transmits remote control signals about which button on the remote control has been pressed to the central electronic module via the Controller area network (CAN).

SYSTEM OVERVIEW

LOCATION OF COMPONENTS

Fig. 261: Central Locking Components
Courtesy of VOLVO CARS CORPORATION

The central locking function uses the following components (may differ depending on model, model year, options and market):

Position	Component	Position	Component
3/73	Power child lock switch	4/56	Central electronic module
3/74-3/77	Switches in door locks	4/58	Rear electronic module
3/78	Switch in trunk lock	4/70	Upper electronic module
3/111	Light switch module	5/1	Driver information module
3/112	Climate control module	6/37	Lock motor for the fuel tank filler cover
3/126, 3/127	Drivers door module / Passenger door module	10/13, 10/14	Turn signal lamp, front
3/173	Valet lock switch	10/15, 10/16	Turn signal lamp, front fender
3/174	Switch for reduced alarm.	10/54, 10/47	Turn signal lamp, rear
4/9	SRS (supplemental restraint system) control module		Key and lock cylinder
4/16	The brake control module, 2002-/ ABS-control module, 1999-2001.		Remote control

LOCKING SYSTEM

The lock system is available in the following versions:

- Central locking with single step unlocking
- Central locking deadlock (differs in the lock unit from single step unlocking). Not available in USA and Canada
- Central locking with power child lock. Market dependent
- Central locking with two step unlocking and *without* fuel tank filler cover opening via remote switch. Applies to the USA and Canada only
- Central locking with two step unlocking and *with* fuel tank filler cover opening via remote switch. Applies to the USA and Canada only.

The number of switches, electrical motors in the door and relays, differs depending on the model year, version and type. The same control modules are used in different versions. The software differs on the type of lock, locking system and model. It is possible to shift between single step unlocking and two step unlocking by downloading new software.

INITIATION

The central locking system must be reinitiated after the battery has been disconnected. This is carried out by unlocking the car using either the remote control or the key in the driver's door. If the central locking system is not initiated, the switches in the driver's door module and the passenger door module will not work.

FUNCTION

The user can control the different central locking functions using:

- The key in the driver's door lock cylinder
- Remote control
- The switches in the driver's door module and the passenger door module
- The switches in the center console
- The switch on the control module for the light switch module for opening the fuel tank filler cover. Only applies to cars with a fuel tank filler cover remote switch.

The number of switches, lock cylinders, differs depending on the version of lock system.

LOCKING AND UNLOCKING DOORS

The doors can be locked:

- Using the key in the driver's door lock cylinder
- Using the remote control LOCK button
- Using the switches in the driver's door module and the passenger door module The function is disabled if the car is locked from outside or using the remote control. For single step locking all doors must be closed

so that locking can be carried out using the switch. For two step unlocking with the ignition key removed all the doors lock at the same time using the switch even if a door is open.

NOTE: **If the ignition key is in the ignition switch the car cannot be locked using the remote control or using a key in the driver's door. If the ignition key is in the ignition switch and the driver's door is open and the button on the driver's door module is pressed then the doors lock and immediately unlock. These two functions prevent locking the key in the car.**

The doors can be unlocked:

- Using the key in the driver's door lock cylinder
- Using the remote control UNLOCK button
- Using the switches in the driver's door module and the passenger door module The function is disabled if the car is locked using a key or using the remote control
- Via a request from the SRS (supplemental restraint system) control module in the event of a collision.

LOCKING AND UNLOCKING THE FUEL TANK FILLER COVER, MODELS WITHOUT FUEL TANK FILLER COVER OPENING VIA REMOTE SWITCH

The fuel tank filler cover can be locked:

- Using the key in the driver's door lock cylinder (fuel tank filler cover locking is delayed 10 min, from structure week 200020 inclusive)
- Using the remote control LOCK button (fuel tank filler cover locking is delayed 10 min, from structure week 200020 inclusive)
- Using the switches in the driver's door module and the passenger door module (from structure week 200020 inclusive the switch inside the car is disconnected from the fuel tank filler cover lock). The function is disabled if the car is locked from outside or using the remote control.

The fuel tank filler cover can be unlocked:

- Using the key in the driver's door lock cylinder
- Using the remote control UNLOCK button
- Using the switches in the driver's door module and the passenger door module (from structure week 200020 inclusive the switch inside the car is disconnected from the fuel tank filler cover lock). The function is disabled if the car is locked from outside or using the remote control.

LOCKING AND UNLOCKING THE FUEL TANK FILLER COVER, MODELS WITH FUEL TANK FILLER COVER OPENING VIA REMOTE SWITCH (MARKET DEPENDANT)

The fuel tank filler cover can be locked:

- Automatically when the speed of the car exceeds 7 km/h (5 mph).

The fuel tank filler cover can be unlocked:

- Using the switch above the light switch.

At 7 km/h (5 mph) the fuel tank filler cover locks automatically and remains locked until the switch is reactivated. The fuel tank filler cover lock is unaffected by the remote control. Locking and unlocking the doors and other hatches is carried out the same way as for models *without* fuel tank filler cover opening via remote switch.

Models *with* fuel tank filler cover opening via remote switch are equipped with a fuel leakage detecting system. The system for fuel leakage detecting pressurizes the fuel system to trace any leakage. The test is carried after the ignition has been switched off. When the switch is activated any leakage detection underway is stopped to evacuate the over pressure from the fuel tank. The over pressure is evacuated to prevent the fuel from traveling up the fuel filler pipe when the fuel tank filler cap is opened.

AUTOMATIC FUNCTIONS

- If the car is unlocked and no doors are opened within 2 minutes the car relocks automatically
- If the lock button in the driver or passenger doors is depressed when the door is open the switch returns to the upper (unlocked) position
- When the tailgate has been unlocked using the remote control, the tailgate locks automatically when it closes.
- The doors and hatches lock automatically at speeds above 7 km/h (5 mph), (option, market dependent)
- When the SRS (supplemental restraint system) control module registers a collision all the doors and hatches unlock.

DEADLOCKED (MARKET DEPENDENT)

If the car is locked using the key or the remote control the deadlock is activated after approximately 25 seconds. The doors cannot be opened from the inside.

If a door is opened from the inside before the deadlock is engaged, deadlock will not be activated. In order to lock the car again the car must be unlocked first. Then the car can be locked as normal.

The deadlock is deactivated if, when the car is locked, the ignition key is inserted in the ignition switch and turned to position II.

The function can be disconnected using the switch for the reduced alarm in the center console.

Information that the function is disengaged is given by:

- the LED in the button remaining lit until the car is locked
- a text message being displayed in the driver information module.

Next time the ignition key is inserted and turned to position II, the system is reset. To obtain reduced alarm the switch must be reactivated.

TWO STEP UNLOCKING (MARKET DEPENDENT)

Certain markets have two step unlocking. The differences are:

- When unlocking using the key, the key must be turned anticlockwise twice within 10 seconds to unlock all the doors and hatches
- When unlocking using the remote control, the UNLOCK button must be pressed twice within 10 seconds to unlock all the doors and hatches. On cars with the fuel tank filler cover opening via remote switch, the fuel tank filler cover only opens via the switch
- To unlock the driver's door and fuel tank filler cover using the key, turn the key anticlockwise once. On cars with the fuel tank filler cover opening via remote switch, the fuel tank filler cover only opens via the switch
- To unlock the driver's door and fuel tank filler cover using the remote control, press the UNLOCK button once. On cars with the fuel tank filler cover opening via remote switch, the fuel tank filler cover only opens via the switch
- If the driver's door is open at the same time that the switch in the driver's door is used for locking, the car will lock. That is on the condition that the key is not in the ignition switch.

For more information, see **LOCKING AND UNLOCKING THE FUEL TANK FILLER COVER, MODELS WITH FUEL TANK FILLER COVER OPENING VIA REMOTE SWITCH (MARKET DEPENDANT)**.

POWER CHILD LOCK (OPTION)

Mechanical (manual) child locks are standard in the back doors.

A power child lock is available as a factory installed option. The child lock is activated / deactivated using a switch in the climate control unit panel.

Cars equipped with two stage unlocking (USA, Canada) are not equipped with the power child locks.

ACKNOWLEDGMENT (MARKET DEPENDENT)

The lock system provides a visual acknowledgment when locking and unlocking.

When the car is locked this is acknowledged by a long single flash from the turn signal lamps. If a door or hatch is open when the car is locked, the flash is delayed until these are closed. Applies only to cars equipped with an alarm.

When the car is unlocked this is either not acknowledged or acknowledged by two short flashes from the turn signal lamps.

This function is market dependent and is programmed via VIDA (Volvo scan tool).

CENTRAL LOCKING (2005-2012)

DIAGNOSTIC FUNCTIONS

GENERAL INFORMATION

The control modules have a built-in diagnostic system, Volvo Diagnostics, which continuously monitors internal functions as well as input and output signals. The central locking system is a distributed system which stores diagnostic trouble codes (DTCs) in different control modules depending on where the fault occurred.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if a control module detects a fault in a connected component.

If for some reason a fault disappears after the diagnostic trouble code (DTC) has been permanently stored in a control module, information about the fault remains in the control module.

Rear electronic module (REM)

Rear electronic module (REM) can identify 12 different faults associated with the central locking system and can store up to 10 diagnostic trouble codes (DTCs) simultaneously.

Driver door module (DDM)

Driver door module (DDM) can identify 20 different faults associated with the central locking system and can store up to 10 diagnostic trouble codes (DTCs) simultaneously.

Passenger door module (PDM)

Passenger door module (PDM) can identify 20 different faults associated with the central locking system and can store up to 10 diagnostic trouble codes (DTCs) simultaneously.

ACTIVATING COMPONENTS AND FUNCTIONS

A number of activations can be performed via VIDA Vehicle communication:

- Lock motor, left-hand/right-hand rear door, lock/unlock
- Lock motor, trunk lid/tailgate, lock/unlock
- Lock motor, fuel tank filler cap, lock/unlock
- Lock motor, child safety locks, lock/unlock

FUNCTION

GENERAL INFORMATION

The lock function which is activated on delivery depends on the market. The central locking system can be configured for standard locking function or 2 stage locking function. For the standard locking function the central locking system can also include the deadlocking function.

STANDARD LOCKING FUNCTION

Fig. 262: Door Lock Communication Diagram
Courtesy of VOLVO CARS CORPORATION

Standard locking function means that all doors and hatches are locked or unlocked simultaneously. The exception is the fuel tank filler cover which is unlocked with unlocking but locked after 10 minutes or when the vehicle reaches a speed of 16 km/h (10 mph). With locking or unlocking a confirmation is normally given via the direction indicators that the central locking has successfully performed the operation. If locking or unlocking did not succeed no confirmation is given. This confirmation also applies to the alarm functions if an alarm is installed in the vehicle.

Locking/unlocking of the vehicle can be performed with:

- the key in the driver's door lock cylinder
- buttons on the remote control
- the central locking switches on the inside of the front side doors.

When using the key:

When locking with the key in the door lock, a hatch or a door can still be open. Doors and locks will be locked and remain locked after being closed. However, the alarm will not be activated if the vehicle has this setting (key set). This setting is made in the vehicle's configuration file which is stored in the central electronic module (CEM).

The switches on the inside of the front side doors are deactivated if the vehicle is locked with a key. To be able to lock the vehicle with the switches all doors must be closed.

When locking with the remote control:

For remote control locking to be possible there must no key belonging to the vehicle in the ignition switch.

When locking, one or more doors or hatches can still be open. The alarm functions will be activated and confirmation given when the last door or hatch is closed. If the function for deadlocking is installed then this will be activated 25 seconds after the last side door is closed. The fuel tank filler cover is locked automatically after 10 minutes.

When locking with central locking switches:

Locking with central locking switches can only take place if all doors are closed. If a door is open when a switch is pressed then the doors will be locked and then immediately unlocked again. The central locking switches are disconnected when the vehicle is locked from the outside, with a key or the remote control.

Normally the vehicle is unlocked by activating the remote control unlocking button. Depending on settings, this can also deactivate the alarm if installed. If the setting for alarm deactivation on key unlocking is not made then the alarm will be triggered if the vehicle is unlocked with a key. The alarm can then be reset by inserting the ignition key into the ignition switch.

2 STAGE LOCKING FUNCTION

Fig. 263: Door Lock Communication Diagram
Courtesy of VOLVO CARS CORPORATION

In principle the 2 stage locking function is used exclusively on the American market. The function means that the front doors can be unlocked in two stages. Locking and unlocking can either take place with a key or remote control. Locking can also take place with the inner central locking switches in the front side doors.

Locking/unlocking with the key:

Locking and unlocking is performed via the lock cylinder in the driver's door. To unlock all doors and hatches the key must be turned counter clockwise twice within 10 seconds. The first key turn unlocks the driver's door and the fuel tank filler cap. The second key turn unlocks the other side doors and tailgate/trunk lid. To lock, the key only needs to be turned clockwise once for all doors and hatches to be locked. The vehicle can be locked with a key even if a door or hatch is open.

Locking/unlocking with remote control:

When unlocking with the remote control, the driver's door and fuel tank filler cover are unlocked with the first press on the remote control. To unlock the other doors and hatches the unlocking button must be pressed once more within 10 seconds. When locking the locking button only needs to be pressed once.

Locking with central locking switches:

Locking can be performed with one of the inner central locking switches on condition that the door where the

switch is pressed is open. However, the alarm functions will not be activated if the locking takes place with the switch on the driver's door. The vehicle will be locked when the last door is closed.

STANDARD LOCKING FUNCTION WITH DEADLOCKING

Fig. 264: Door Lock Communication Diagram
Courtesy of VOLVO CARS CORPORATION

The function in the locking system for locks with deadlocking is the same as in the standard locking system. There is an extra lock motor in the lock units for the deadlocking function. The function of this lock motor is to mechanically disconnect the lock unit in the door from the door handles. The function is normally activated automatically 25 seconds after the vehicle has been locked and the last door closed. This means for example that a side door cannot be opened even if a window is broken.

NOTE: This also means that anybody remaining in the vehicle when it is locked cannot leave. The function can be temporarily disconnected with the switch for reduced alarm which is located on the dashboard environment panel.

CHILD-PROOF LOCKS

Fig. 265: Child-Proof Locks Communication Diagram
Courtesy of VOLVO CARS CORPORATION

The function for child safety locks involves an extra lock motor in each rear lock unit. The function is only available for the rear doors. The lock motor disconnects the inner door handle and the lock button on each rear door and this means that the door cannot be opened from the inside. However, the door can still be opened from the outside.

The function is activated with a switch on the dashboard environment panel for climate control when the ignition key is position I or II. The switch has an alternating function which connects or disconnects the function with every other press. The switch for activation has an integral LED to indicate the activated function. A message is also displayed in the text window of the driver information module (DIM).

The child safety lock status is saved as a setting in the rear electronic module (REM) and is also valid after the ignition has been switched off and then on again. In order to deactivate the function the ignition key must be turned to position I or II and the switch on the dashboard environment panel pressed in so that the LED goes out. A message will then be displayed in the text window of the driver information module (DIM). The rear electronic module (REM) receives a signal from the lock units in the rear doors that the lock motor is in the locked position.

If the indication from the lock motors is incorrect or fails to appear, or if activation or deactivation is not successful, then a diagnostic trouble code (DTC) is generated in the rear electronic module (REM). A message will also be displayed in the driver information module (DIM).

OPENING THE TRUNK LID/TAILGATE

The tailgate/trunk lid can be opened in two ways:

- the switch on the tailgate/trunk lid
- the button on the remote control.

As a reserve alternative where appropriate the tailgate/trunk lid can be opened with a key in the lock cylinder on

the tailgate/trunk lid.

The lock unit in the tailgate is locked and unlocked by the rear electronic module (REM) together with the side doors. The handle on the tailgate is mechanically connected to the lock mechanism. The tailgate can be opened using the button on the remote control even if the rest of the vehicle is locked. In order to open the tailgate the button on the remote control must be pressed twice within 3 seconds.

If the button on the remote control is pressed a message is sent from the remote control. This message is received by the upper electronic module (UEM) which checks that the key belongs to the vehicle. If this is the case then the upper electronic module (UEM) sends a request for lock motor activation to the rear electronic module (REM).

NOTE: If the vehicle has been locked and the tailgate/trunk lid is unlocked using the remote control then the LOCK button on the remote control must be pressed in after the tailgate/trunk lid is closed. This is so that the central locking has locked status and the alarm is activated.

LOCKING/UNLOCKING THE FUEL TANK FILLER COVER

Locking and unlocking the fuel tank filler cover takes place at different points depending on the configuration of the vehicle.

Standard locking function

The fuel tank filler cover is locked 10 minutes after the vehicle is locked and unlocked at the same time as the other doors and hatches. The exception is if the vehicle is locked with one of the inner lock buttons, when the fuel tank filler cover is locked immediately.

2 stage locking function

The fuel tank filler cover locks automatically after 10 minutes or when the vehicle is locked.

The fuel tank filler cover is unlocked together with the driver's door with the first press on the remote control or with the first turn of the key in the lock cylinder in the driver's door.

Automatic locking of the fuel tank filler cover when the vehicle reaches a speed of 7 km/h (5 mph) can be specified as an automatic function with all configurations.

If the vehicle is equipped with the system for automatic fuel leakage detection then the fuel tank filler cover can only be opened with a switch located on the light switch module (LSM). Light switch module (LSM) communicates in serial with the central electronic module (CEM). Central electronic module (CEM) forwards the request to the rear electronic module (REM).

The cover can only be opened if the speed of the vehicle is less than 16 km/h (10 mph). With one press on the switch it can take up to 1.5 seconds before the cover opens. This is so that overpressure in the fuel tank can be equalized before the fuel tank filler cap is removed.

This function is only available for the American market.

INDICATION OF THE STATUS OF THE DOORS, HATCHES AND LOCK MOTORS

There can be up to three contact breakers in the side door lock units:

- contact breaker which indicates if the door is not closed
- contact breaker to indicate that the central locking motor is in the locked position
- contact breaker for whether the child safety lock motor is in the locked position.

Each contact breaker provides a ground connection on an input to the rear electronic module (REM) when the contact breaker is closed.

Contact breaker for open door indication is used:

- to generate a message on whether a door is opened during the journey
- to indicate to the rear electronic module (REM) whether or not the vehicle is ready for locking (depending on lock configuration)
- to activate and trigger the alarm function if installed in the vehicle.

Contact breaker for central locking motor indication is used to check whether locking or unlocking has been successful or not.

Contact breakers for child safety locks are only available in the rear doors and indicate that the child safety lock is activated.

There is only one contact breaker in the lock unit in the tailgate/trunk lid. This indicates whether the tailgate/trunk lid is open or closed.

The signals are also used to activate the locking and alarm function, for example if locking takes place while a door is still open. If the central locking is locked and a door is open then a light signal will come on, and the alarm will be activated when the last door is closed.

If the vehicle is equipped with an alarm then there is also a contact breaker at the hood. However, this has no role in the central locking system, but the contact breaker is used to trigger the alarm if installed.

AUTOMATIC LOCKING WHEN DRIVING

Whether the function for automatic locking is activated or not at delivery depends on the market. If the function is activated then the side doors are locked when the speed exceeds 7 km/h (5 mph). This is on condition that all side doors are closed, the engine is running and the vehicle is moving forwards. The exception is the tailgate/trunk lid which may be open. The rear electronic module (REM) receives information on whether or not the engine is running from the engine control module (ECM).

The indication that the engine is driving the vehicle forward differs between vehicles with automatic or manual transmission. On vehicles with automatic transmission the position of the gear selector is obtained from the transmission control module (TCM). The gear selector must not be in Park (P) or Neutral (N) position for the

automatic locking to work. On vehicles with manual transmission the rear electronic module (REM) receives information on the speed of the vehicle from the brake control module (BCM). At the same time the accelerator pedal must be partially actuated for the locking to be performed.

The door can be unlocked again with a normal unlocking procedure

An unlocking procedure activates the function. Example: the vehicle is unlocked, started and driven off. When the vehicle exceeds 7 km/h (5 mph) the side doors not already locked will be locked. If the vehicle then stops and the side doors are unlocked for a passenger to get out, e. g. with one of the central locking switches, then the vehicle will *not* be automatically locked the next time the vehicle exceeds 7 km/h (5 mph). However, if the passenger getting out opens the door by pulling in the inner door handle or unlocks the door using the lock button then the door will be locked when the vehicle next exceeds 7 km/h (5 mph).

AUTOMATIC LOCKING AFTER UNLOCKING

If the vehicle is unlocked with the remote control and no side door or tailgate/trunk lid is opened within 2 minutes then the vehicle will automatically lock again. If the vehicle is unlocked with a key then there will be no re-locking. Whether the function is activated or not at delivery depends on the market.

SIGNALS

The tables below summarize the input and output signals to the units in the central locking function. The signal types are divided into directly connected signals and Controller Area Network (CAN) communication.

REAR ELECTRONIC MODULE (REM) (4/58):

Input signals	Output signals
Directly connected: • Contact breaker in lock unit, driver's door, for indicating open door. • Contact breaker in lock unit, passenger door, for indicating open door. • Contact breaker in lock unit, right-hand rear door, for indicating open door. • Contact breaker in lock unit, left-hand rear door, for indicating open door. • Contact breaker in lock unit, tailgate/trunk lid, for indicating open tailgate/trunk lid. • Contact breaker, hood, for indicating open hood (only vehicles with alarm). • Contact breaker in lock unit, left-hand rear door, for indicating lock motor status. • Contact breaker in lock unit, right-hand rear door, for indicating lock motor status.	**Directly connected:** • Lock unit, tailgate/trunk lid, for activating lock motor. • Lock motor, fuel tank filler cover, for activating lock motor. • Lock unit in left-hand rear door, for activating lock motors. • Lock unit in right-hand rear door, for activating lock motors.
Via Controller Area Network (CAN) communication:	**Via Controller Area Network (CAN) communication:**

• Driver door module (DDM), for status information on certain lock motors. • Passenger door module (PDM), for status information on certain lock motors. • Engine control module (ECM) for information on the status of the engine. • Brake control module (BCM), for information on vehicle speed. • Transmission control module (TCM), indicates the position of the gear selector. • Central electronic module (CEM), for information on the type of key used to unlock the vehicle and the request to open the fuel tank filler cover.	• Driver door module (DDM), for locking and unlocking commands. • Passenger door module (PDM), for locking and unlocking commands. • Central electronic module (CEM), with the request for acknowledgment via direction indicators and activation of acoustic signal (key warning).

DRIVER DOOR MODULE (DDM) (3/126):

Input signals	Output signals
Directly connected: • Indication of locked mode from the lock motor • Central locking switch	**Directly connected:** • Output signal to driver's door lock unit for activation of central locking motor. • Output signal to driver's door lock unit for activation of deadlocking motor.
Via Controller Area Network (CAN) communication: • Rear electronic module (REM), for locking and unlocking commands.	**Via Controller Area Network (CAN) communication:** • Rear electronic module (REM), for status information on certain lock motors.

PASSENGER DOOR MODULE (PDM) (3/127):

Input signals	Output signals
Directly connected: • Indication of locked mode from the lock motor • Central locking switch	**Directly connected:** • Output signal to passenger door lock unit for activation of central locking motor. • Output signal to passenger door lock unit for activation of deadlocking motor.
Via Controller Area Network (CAN) communication: • Rear electronic module (REM), for locking and unlocking commands.	**Via Controller Area Network (CAN) communication:** • Rear electronic module (REM), for status information on certain lock motors.

CLIMATE CONTROL MODULE (CCM) (3/112):

Input signals	Output signals
Via Controller Area Network (CAN)	**Via Controller Area Network (CAN)**

communication: • Rear electronic module (REM), for activation of LEDs in switches for activated function (private locking, child safety locks, reduced alarm).	**communication:** • Rear electronic module (REM), if switch for reduced alarm is pressed (no deadlocking). • Rear electronic module (REM), if switch for child safety locks is pressed (option).

DRIVER INFORMATION MODULE (DIM) (5/1):

Input signals	Output signals
Via Controller Area Network (CAN) communication: • Rear electronic module (REM), for information on whether information lamp or warning lamp is to be lit. • Rear electronic module (REM), for information on which text message is to be displayed. • Central electronic module (CEM), for activation of acoustic signal (key warning).	**Via Controller Area Network (CAN) communication:** -

UPPER ELECTRONIC MODULE (UEM) (4/70):

Input signals	Output signals
Wireless communication: • Signal from remote control.	**Wireless communication:** -
Via Controller Area Network (CAN) communication: -	**Via Controller Area Network (CAN) communication:** • Rear electronic module (REM), with the request for activation of a function. • Central electronic module (CEM), Comfort functions.

CENTRAL ELECTRONIC MODULE (CEM) (4/56):

Input signals	Output signals
Directly connected: • Light switch module (LSM) (3/111), signal from switch for opening fuel tank filler cover.	**Directly connected:** -

SYSTEM DESCRIPTION/DESIGN

GENERAL INFORMATION

Fig. 266: Electrical Modules
Courtesy of VOLVO CARS CORPORATION

The central locking system is a distributed system. Those parts which are included in the system are:

- rear electronic module (REM)
- central electronic module (CEM)
- driver door module (DDM)
- passenger door module (PDM)
- driver information module (DIM)
- climate control module (CCM)
- upper electronic module (UEM)
- switch for unlocking the fuel tank filler cover
- lock units in doors
- lock motor at the fuel tank filler cover
- lock unit for tailgate/trunk lid.

REAR ELECTRONIC MODULE (REM)

Fig. 267: Locating Rear Electronic Module (REM)
Courtesy of VOLVO CARS CORPORATION

Rear electronic module (REM) (4/58) controls and monitors the central locking system and its functions. The control module is located under the protective panel on the left-hand side of the cargo compartment. No door or hatch can be unlocked without a command from the rear electronic module (REM). The rear electronic module (REM) continuously follows up the status of the system with respect to the status of door and lock motors.

Rear electronic module (REM) is supplied with power from the ignition switch and is grounded in the body.

CENTRAL ELECTRONIC MODULE (CEM)

Fig. 268: CEM
Courtesy of VOLVO CARS CORPORATION

Central electronic module (CEM) (4/56) is located behind the dashboard, beside the driver. The function of the central electronic module (CEM) in the central locking system is:

- to activate the direction indicators, as confirmation with locking and unlocking the central locking
- to send a command, to activate the acoustic signal in the driver information module (DIM) with the function for key warning
- to send a message to the rear electronic module (REM), on the type of key used to unlock the vehicle or the type of key for switching on the ignition. This is significant for activating and deactivating private

locking.
- to forward the request for unlocking the fuel tank filler cover from the light switch module (LSM).

Central electronic module (CEM) communicates with the rear electronic module (REM) via the low-speed side of the CAN network.

DRIVER DOOR MODULE (DDM) / PASSENGER DOOR MODULE (PDM)

Fig. 269: Locating Driver Door Module And Passenger Door Module
Courtesy of VOLVO CARS CORPORATION

Driver door module (DDM) (3/126) is located in the driver's door and the passenger door module (PDM) (3/127) is located in the passenger door. Amongst other things, switches for window lifts are located on the top part of the control modules. The appearance and physical design differs between the two control modules.

The control panel on the driver's side has control buttons for setting the door mirrors and window lifts.

The control panel on the passenger side has control buttons for the power window mechanism.

Also on each front side door is a button for locking and unlocking central locking.

Driver door module (DDM) and the passenger door module (PDM) are directly connected to the lock unit in each door. Driver door module (DDM) and the passenger door module (PDM) lock and unlock the door on a command from the rear electronic module (REM). Driver door module (DDM) and the passenger door module (PDM) can only unlock the door after receiving a signal from the rear electronic module (REM).

Driver door module (DDM) and the passenger door module (PDM) have diagnostic functions which monitor the function of the buttons with respect to jammed buttons and relays.

Driver door module (DDM) and the passenger door module (PDM) communicate with the rear electronic module (REM) via the low-speed side of the CAN network.

DRIVER INFORMATION MODULE (DIM)

Fig. 270: Driver Information Module Display Area
Courtesy of VOLVO CARS CORPORATION

Driver information module (DIM) (5/1) displays a message in the text display and lights a warning lamp if one of the side doors or a hatch has opened during the journey. If the doors or hatches are fully closed then this is indicated by means of contact breakers in the lock units. A contact breaker at the hood is only fitted on vehicles with alarm.

A yellow warning lamp lights if the vehicle speed is below 7 km/h (5 mph). The red warning lamp lights if the vehicle speed is above 7 km/h (5 mph).

The tailgate is only indicated by a text message and yellow warning lamp, irrespective of the speed.

Driver information module (DIM) also displays a message with activation and deactivation of the functions private locking, child safety locks, and when the fuel tank filler cover is opened. The driver information module (DIM) also emits an acoustic signal with the function for key warning.

Driver information module (DIM) communicates with the rear electronic module (REM) via the low-speed side of the CAN network.

CLIMATE CONTROL MODULE (CCM)

Fig. 271: Dashboard Environment Panel
Courtesy of VOLVO CARS CORPORATION

Climate control module (CCM) (3/112) receives the signals from the switches furthest down on the dashboard environment panel (7 in a row). Located here amongst other things are switches for private locking, child safety locks and reduced alarm.

NOTE: The switches may be arranged in a different order from the one shown in the illustration depending on the vehicle's configuration and equipment.

When one of the switches is pressed the climate control module (CCM) sends a request over the CAN network to the rear electronic module (REM) that the corresponding function is activated or deactivated.

The climate control module (CCM) communicates with the rear electronic module (REM) via the low-speed side of the CAN network.

UPPER ELECTRONIC MODULE (UEM)

Fig. 272: Identifying Rear View Mirror
Courtesy of VOLVO CARS CORPORATION

Upper electronic module (UEM) receives the signals from the remote control and checks that the remote control belongs to the vehicle. For the upper electronic module (UEM) to be able to perform the check it must be programmed with codes for the remote controls belonging to the vehicle. If the key being used is approved then a request is sent for unlocking or locking to the rear electronic module (REM).

Upper electronic module (UEM) communicates with the rear electronic module (REM) via the low-speed side of the CAN network.

SWITCH FOR UNLOCKING THE FUEL TANK FILLER COVER

Fig. 273: Fuel Tank Filler Cover Switch
Courtesy of VOLVO CARS CORPORATION

The switch for unlocking the fuel tank filler cover is located on the light switch module (LSM) (3/111). The switch is only on vehicles with fuel tank leakage diagnostics.

Light switch module (LSM) communicates in serial with the central electronic module (CEM). If the switch is pressed the central electronic module (CEM) sends a request to the rear electronic module (REM) that the lock motor for the fuel tank filler cover is activated. The cover can be opened if the speed of the vehicle is less than 7 km/h (5 mph).

The fuel tank filler cover is opened after a delay so that the automatic check for fuel leakage can be interrupted and the fuel tank pressure equalized. The fuel tank filler cover is then locked when the vehicle reaches a speed of 16 km/h (10 mph) or after 10 minutes if the vehicle has 2 stage locking function.

LOCK UNITS SIDE DOORS

Fig. 274: Side Door Lock Units
Courtesy of VOLVO CARS CORPORATION

The lock units (3/74-77) are fitted in the rear of the side doors. The lock units in the front doors are each directly connected to their associated control module in the door. The lock units in the rear doors are directly connected to the rear electronic module (REM).

There are different versions of the lock units, depending on the configuration of the lock motors.

There are two versions of the lock units in the front doors with lock motors for:

- central locking
- central locking and deadlocking.

There are four versions of the lock units in the rear doors with lock motors for:

- central locking
- central locking and deadlocking
- central locking, deadlocking and child-proof locking
- central locking and child-proof locking.

The central locking lock motor locks the door.

The deadlocking lock motor disconnects the mechanical couplings from the door handles and the lock button to the lock unit. This function depends on the market.

The lock motor for child safety locks is only for the rear doors and disconnects the inner door handle and the lock button.

Driver door module (DDM) and the passenger door module (PDM) can only unlock the doors after a command from the rear electronic module (REM).

In addition to the lock motors, the lock units contain up to three contract breakers depending on the configuration:

- contact breaker to indicate that the central locking motor is in the locked position
- contact breaker which indicates that the door is not locked
- contact breaker to indicate the child-proof lock motor is locked.

The lock motors have integral overheating protection which prevents lock motor activation if the lock motor risks becoming too hot.

LOCK UNIT, TAILGATE/TRUNK LID

Fig. 275: Tailgate/Trunk Lid Lock Unit
Courtesy of VOLVO CARS CORPORATION

The lock unit in the tailgate locks and unlocks during a normal locking procedure. When the tailgate is unlocked and the handle on the tailgate is pressed the catch in the mechanism from the lock brace in the body disengages and the tailgate opens.

There is a lock cylinder on the tailgate on the XC90 if a third row of seats was fitted at the factory.

The tailgate/trunk lid can also be unlocked/opened separately with a special button on the remote control.

REMOTE CONTROL

Fig. 276: Identifying Ignition Key
Courtesy of VOLVO CARS CORPORATION

The remote control is used to activate function in the system remotely. The basic functions of the remote control are:

- unlocking
- locking
- unlocking the trunk lid/tailgate
- activating the local lighting

- activating alarm functions.

The remote control has an integrated communication circuit and memory. When a button on the remote control is pressed a coded signal is sent out. This signal is received by the upper electronic module (UEM) and is forwarded to the rear electronic module (REM). In order that the remote control can work with the system a unique code must be programmed into the remote control by the upper electronic module (UEM). This is first performed at the factory. Following which remote controls can be added or removed at a Volvo workshop.

The remote control has an integral battery which is used when commands are sent to the system. This battery requires replacement at regular intervals. An indication of a weak battery is when the range of the remote control decreases.

SYSTEM OVERVIEW

GENERAL INFORMATION

Fig. 277: Electrical Modules
Courtesy of VOLVO CARS CORPORATION

The central locking system includes a number of functions. The main unit of the system is the rear electronic module (REM) (4/58). The rear electronic module (REM) communicates with the internal components both via direct connections and the CAN network.

The functions covered are:

- standard locking function
- 2 stage locking function
- deadlocking
- private locking mode
- child safety locks
- unlocking the trunk lid/tailgate
- unlocking the fuel tank filler cover
- indication of the status of the doors and hatches
- automatic locking function
- re-locking.

After the battery has been disconnected the central locking system must be initialized. This can be performed by locking and unlocking once with the key in the driver's door or with the remote control. This is performed to ensure that the status for lock motors and doors is operative.

The locking function on the vehicle at delivery depends on the market and is stored in the vehicle's configuration file, which is stored in the central electronic module (CEM). The configuration can be read via VIDA Vehicle communication.

STANDARD LOCKING FUNCTION

The standard locking function unlocks the side doors and the fuel tank filler cover and it activates the lock button on the trunk lid/tailgate so that this can be opened. Total unlocking unlocks all doors and hatches at the same time.

2 STAGE LOCKING FUNCTION

This locking function is used almost exclusively on the American market. The function can either be used via key or via remote control. If the vehicle shall be unlocked with a key then the key must be turned counterclockwise twice within 10 seconds so that all doors and hatches are unlocked. The first key turn unlocks the driver's door and the fuel tank filler cover. The second key turn unlocks the other doors and the tailgate/trunk lid. If the vehicle shall be unlocked with the remote control then the unlocking button must be pressed twice within 10 seconds.

DEADLOCK

The function for deadlocking is optional. Deadlocking means that the inner door handles and the inner lock button are disconnected. This means that a side door cannot be opened from the inside even if a window is broken. Deadlocking is activated 25 seconds after the vehicle is locked. The function can be temporarily disconnected by activating the switch for reduced alarm. The function is not available in the US/CA market.

VALET LOCKING MODE

The cargo compartment can be locked in a "private" mode. The function is used to prevent access to the glove

compartment and cargo compartment if, for example, the vehicle must be left in a workshop along with personal effects. The function is activated by a switch on the dashboard environment panel for climate control. To activate and deactivate the function a key belonging to the vehicle must be used (a "Master Key") and the ignition must be in position II.

CHILD-PROOF LOCKS

The function for child safety locks disconnects the rear inner door handles and the inner lock button. The switch for the function is located in the dashboard environment panel for climate control.

UNLOCKING THE TRUNK LID/TAILGATE

The lock unit in the tailgate is unlocked during a normal unlocking procedure. The tailgate can also be unlocked separately with a button on the remote control. The tailgate can also be opened independently of the central locking system with the key in the lock cylinder on the tailgate. The lock cylinder is only on vehicles with a factory-fitted auxiliary rear facing seat. If the tailgate is opened with the key in the lock cylinder then the alarm will be triggered if more than 26 seconds has elapsed since locking the central locking (applies to vehicles with alarm function).

The lock unit on the tailgate is directly connected to the rear electronic module (REM).

UNLOCKING THE FUEL TANK FILLER COVER

As standard the fuel tank filler cover unlocks at the same time as other doors and locks again after 10 minutes or when the vehicle reaches 16 km/h (10 mph).

If the vehicle is equipped with a fuel leakage diagnostics system then a switch for unlocking the fuel tank filler cover is located on the light switch module (LSM). The light switch module (LSM) communicates in serial with the central electronic module (CEM) and transmits the information if the switch has been pressed. The lock motor for the fuel tank filler cover is located on the rear edge of the fuel tank filler cover. The lock motor is directly connected to the rear electronic module (REM).

CONTACT BREAKERS AT DOORS AND HATCHES.

There are contact breakers in the side door and tailgate/trunk lid lock units which indicate whether the door or tailgate/trunk lid is open or closed, and a contact breaker located at the hood if the vehicle is equipped with alarm. There are no contact breakers by the fuel tank filler cover. The contact breakers are closed if the door or hatch is closed and then provide a direct ground connection to the rear electronic module (REM).

AUTOMATIC LOCKING

The system has a function which can be activated so that the vehicle is locked automatically when it reaches a speed of 7 km/h (5 mph). The function is normally not activated on delivery from the factory, but can be activated afterwards.

RE-LOCKING

The system has a function for re-locking. If the car is unlocked using the remote control or key and the side

doors or trunk lid/tailgate are not opened within 2 minutes, the car will be locked automatically. This function prevents the car from being left unlocked unintentionally.

TEXT MESSAGE FOR THE LOCK SYSTEM

The text message window of the driver information module (DIM) displays whether the function for child safety locks, private locking or reduced alarm is activated. Also displayed here is a warning message if a door or hatch is opened when the ignition is switched on.

ACKNOWLEDGMENTS

Confirmation can be given by the central locking system when locking or unlocking is performed. The basic setting is one long light signal when locking and two short ones when unlocking.

REMOTE CONTROL

The central locking system can be unlocked using the remote control.

The remote control has buttons for:

- unlocking
- locking
- unlocking the trunk lid/tailgate
- panic function
- local lighting.

PANIC FUNCTION

The panic function activates the vehicle's horn for 25 seconds. The function is used to attract attention in an emergency situation. The panic function can be activated by a button on the remote control.

UNLOCKING USING THE KEY

The central locking can be locked and unlocked with a key via the lock cylinder in the driver's door. This applies whether the setting is standard or 2 stage. During this process the alarm functions can also be activated or deactivated. The alarm function depends on a setting in the vehicle's configuration file which is stored in the central electronic module (CEM). If the customer wishes, the alarm can be set to only be activated and deactivated if the vehicle is locked or unlocked with the remote control.

CHASSIS/SUSPENSION (2003-2012)

CHASSIS/SUSPENSION

CHASSIS/SUSPENSION

Fig. 278: Identifying Basic Chassis Dimensions
Courtesy of VOLVO CARS CORPORATION

Height (A)	**Wheelbase** (B)	**Ground clearance** (C)	**Chassis height** (D)	**Weight**	**Track, front**	**Track, rear**
1740 mm	2859 mm	219 mm	1, 521mm	1880 - 2110 kg	1634 mm	1624 mm

Most common SUVs (Sports Utility Vehicles) are based on a type of chassis also found on high trucks. The XC90 is constructed like a passenger car, developed to meet the high handling standards. There is equal weight distribution between the front and rear ends due to the laterally mounted engine and four wheel drive.

The center of gravity is lower resulting in excellent directional stability.

Suspension

Front:

- Individual suspension with MacPherson springs
- Negative steering radius.

Rear:

- Individual suspension, Multilink.

FRONT SUSPENSION

Fig. 279: Identifying Front Suspension Components
Courtesy of VOLVO CARS CORPORATION

1. Anti-roll bar
2. Bearing
3. Coil spring
4. Shock absorber
5. Spring strut
6. Steering arm
7. Wheel hub
8. Ball joint
9. Control arm
10. Bushing.

Individual suspension with MacPherson springs

- Lower control arm, forged
- Ball joint, modified mounting from previous models
- Steering arm, cast iron
- Coil spring, 3 different versions depending on weight.

Steering

- Limiter (plastic sleeve installed inside the steering gear). 70 mm for 16", tire size 225. 65 mm for 17", tire size 235
- The steering gear is made by ZF
- Speed dependent power steering. Option.

REAR SPRING/REAR SUSPENSION

Fig. 280: Identifying Rear Suspension Components
Courtesy of VOLVO CARS CORPORATION

1. Subframe
2. Coil spring
3. Shock absorber, nivomat
4. Rear control arm

5. Cross stay, anti-roll bar
6. Adjustment stay
7. Bump rubber
8. Wheel spindle
9. Hub
10. Front control arm
11. Lower control arm
12. Bracket
13. Anti-roll bar.

The coil spring and shock absorber are mounted separately in the subframe.

- There are six (6) different types of coil spring (depending on weight, soft, medium, hard)
- The coil spring is oval where it meets the lower control arm. It can only be installed in one way
- The coil spring has a color marking which must be facing the marking on the lower control arm.

Shock absorber, the upper bushing is oval shaped to reduce side forces.

- The bushing is stiffer longitudinally
- Nivomat is standard on the seven seater version. For five seater versions it is an option or accessory.

The front and rear anti-roll bars are both 23 mm thick.

- The anti-roll bar is solid. It is manufactured from spring steel.

The subframe is manufactured in steel.

CLIMATE CONTROL (2003-2012)

DESIGN

AIR CONDITIONING

See: **AIR CONDITIONING**

AIR CONDITIONING (A/C) REAR, SEVEN SEAT XC90 (OPTION)

See: **AIR CONDITIONING (A/C) REAR, SEVEN SEAT XC90 (OPTION)**

AIR DISTRIBUTION SYSTEM

See: **AIR DISTRIBUTION SYSTEM**

BLOWER FAN

Fig. 281: Blower Fan
Courtesy of VOLVO CARS CORPORATION

The fan wheel is the radial type with a guide vane rim on the outer edge. The fan wheel is balanced using steel clips.

The blower fan motor is a permanent magnet type fan.

The blower fan has stepless electronic control.

The power unit is mounted under the fan unit. The power unit can be removed.

FILTER

Fig. 282: Filter
Courtesy of VOLVO CARS CORPORATION

The filter is located after the fan to also clean recirculated air. The filter is coded, that is, designed so that it cannot be installed incorrectly.

There are two types of filter.

- Particle filter

- Multi-filter.

The multi-filter filters particles in the same way as the particle filter. The multi-filter contains active carbon which reduces the influx of gases (bad odors) into the passenger compartment.

The multi-filter is only available for vehicles with electronic climate control (ECC) and then in combination with the air quality sensor (AQS).

NOTE: The climate control system has either a particle filter or a multi-filter, never both.

HEAT EXCHANGER

Fig. 283: Heat Exchanger
Courtesy of VOLVO CARS CORPORATION

In order to heat the air in the passenger compartment, the heating system uses the heat that is generated by the engine. The heat exchanger is connected to the cooling system for the engine. The outlet connection for the heat exchanger is located directly on the engine at the point where the pressure and temperature of the coolant are highest. The coolant flows through the cooling ducts for the engine block and on into the heat exchanger. The return flow is connected to the return pipe on the suction side of the water pump.

The heat exchanger comprises a pipe loop through which the engine coolant flows. The pipe has flanges that provide heat to the airflow.

Engine coolant constantly flows through the heat exchanger. There is no valve to regulate the flow. The selected temperature is achieved using dampers for the right and left-hand sides of the car installed upstream of the heater element. These control the amount of air to be warmed. There is also a damper after the heater element which guides air out into the passenger compartment through the various vents.

Fig. 284: Electric Pump
Courtesy of VOLVO CARS CORPORATION

Vehicles with engine B8444S have an electric pump in the coolant circuit to ensure a comfortable level of heating is supplied to the passenger compartment. The electric pump increases the amount of coolant the flows through the heat exchanger. The pump is located in the engine compartment within the front fender in front of the front left wheel housing.

ADDITIONAL HEATER/PARKING HEATER

Fig. 285: Additional Heater/Parking Heater
Courtesy of VOLVO CARS CORPORATION

1. Control module
2. Water pump
3. Fan shroud
4. Fuel pump (FP) (in front of the fuel tank)
5. Heat exchanger

Gasoline driven vehicles can use a parking heater with timer function.

The additional heater/parking heater are positioned inside the front fenders, in front of the front left wheel arch.

The heater consists of:

- the heater unit
- the combustion preheater module (CPM)
- the exhaust system
- the air intake
- the water pump.

The heater is connected to:

- the engine cooling system
- the vehicle fuel tank
- central electronic module (CEM).

Both versions have a fuel pump (FP) located on the right-hand side in front of the fuel tank.

Vehicles with the parking heater function use the turn signal lamp stalk to control the heater. The information appears in the driver information module (DIM).

LOCATION OF THE COMPONENTS IN THE CLIMATE CONTROL SYSTEM

Fig. 286: Locating Climate Control System Components
Courtesy of VOLVO CARS CORPORATION

1. Heat exchanger
2. Damper motor, temperature, left
3. Blower fan
4. Damper motor, fresh air intake and recirculation damper
5. Power unit for blower fan motor
6. Particle filter or multi-filter
7. Damper motor, ventilation and floor (also defroster for MCC)

8. Damper motor, temperature, right
9. Damper motor, defroster (only ECC)
10. Air quality sensor (AQS)
11. Evaporator temperature sensor.

AIR CONDITIONING

GENERAL INFORMATION

Fig. 287: Climate Control System
Courtesy of VOLVO CARS CORPORATION

There are five main components in the climate control system:

- evaporator
- receiver drier
- compressor
- condenser
- expansion valve.

The system is filled with a suitable quantity of refrigerant and oil. The role of the oil is to lubricate and seal the compressor (piston and cylinder).

A fluorescent leak-tracing agent is added to the refrigerant. The leak-tracing agent makes it possible to trace leaks using UV light.

PRINCIPLE SKETCH OF THE CLIMATE CONTROL SYSTEM

Fig. 288: Identifying Principle Sketch Of Climate Control System
Courtesy of VOLVO CARS CORPORATION

Included in the climate control system:

1. Compressor
2. Condenser
3. Engine cooling fan (the same cooling fan used by the engine cooling system)
4. Receiver drier
5. Expansion valve
6. Evaporator
7. Blower fan.

Explanation:

A - High pressure, warm fluid

B - Low pressure, cold fluid

C - Low pressure, cold gas

D - High pressure, warm gas

Dark arrow - Warm air

Light arrow - Cold air

The system is divided into:

- a low pressure side (B, C)
- a high pressure side (A, D).

The two sides are separated by the compressor (1) and the expansion valve (5). The evaporator (6) is located on the low pressure side and the condenser (2) is on the high pressure side.

The design of the climate control system in a vehicle is based on the laws of nature, which mean that liquids evaporate when they are subjected to a temperature increase or a reduction in pressure and that heat is absorbed during this process.

If the hot vapor is then cooled again, the heat that has been absorbed is released and the gas reverts to liquid form. This process is repeated as many times as necessary, so that "cooling is produced" continually. This is the same type of process as used in refrigerators, for example.

REFRIGERANT

In order to remove heat from the passenger compartment a medium that has a lower evaporating temperature than air is used, because heat will always move from a hotter body to a cooler body. The medium that is used is refrigerant R134a.

R134a is a gaseous fluorocarbon. It is chlorine free and does not damage the ozone layer. However, R134a is still environmentally hazardous as it contributes to the greenhouse effect. It is therefore important that all service work is performed by trained personnel.

R134a retains its gaseous form at normal atmospheric pressure, and only condenses if it is cooled down to below -26 °C.

R134a has the following properties:

- can only be mixed with synthetic PAG oils (polyalkyline glycol) and not with mineral oils
- does not affect metals
- affects some types of plastic, so only special seals (O rings) that are intended for R134a should be used
- is not explosive
- is odorless
- is not toxic in low doses
- effectively absorbs moisture
- is not flammable
- is heavier than air in gaseous form.

COMPRESSOR (NOT B8444S)

Fig. 289: Compressor (Not B8444S)
Courtesy of VOLVO CARS CORPORATION

The compressor is located at the front of the engine. The air conditioning compressor is installed on the auxiliaries bracket which is in turn installed on the cylinder block. There are no bushings between the air conditioning compressor, the auxiliaries bracket and the cylinder block. Direct mounting gives increased rigidity to the mounting. It minimizes the risk of noise.

The compressor is in the refrigerant circuit, located between the evaporator and the condenser.

The compressor has a fixed cylinder displacement.

Compressors with fixed displacement have two limits:

- off
- on.

The air conditioning (A/C) compressor is controlled by an air conditioning (A/C) pressure sensor. The air conditioning (A/C) pressure sensor is positioned on the receiver drier. In vehicles with electronic climate control (ECC), the compressor is also controlled by the temperature after the evaporator.

The compressor is lubricated with specially developed refrigerant oil. This oil (synthetic PAG oil) is mixed with the refrigerant when the air conditioning system is in operation.

The compressor also has a relief valve, located on the rear section of the compressor. The relief valve functions as an additional safety device. The valve opens and releases refrigerant when the pressure in the system is too high (at approx. 3.5 MPa (35 bar)). The valve then shuts again when the pressure has returned to normal.

The compressor is mechanical and is driven by the vehicle engine. When the compressor is operating it "steals" 0.5-8 kW (0.7-11 bhp) from the engine. This may be noticed as slight jerks when driving as the compressor is engaged / disengaged.

The compressor is disengaged for 10 - 20 seconds under full acceleration.

The compressor is the component in the climate control system with the greatest mass. This means that the

compressor takes the longest time to warm up. In climates with large differences in day and night temperatures this means that the compressor is often the coldest part of the system. All the refrigerant in the system therefore gathers in the compressor. The compressor cannot compress liquid which means that the pressure becomes very high and there is a risk that the safety valve will be activated when the system is switched on. The safety valve closes when the pressure falls but there is a slight release of refrigerant each time. When the liquid release occurs it also causes a loud noise and shaking.

To minimize the risk of liquid compression the compressor is engaged at the same time as the starter motor is operating. The starter motor has a lower engine speed (RPM) than the vehicle drive motor and the pressure build up in the compressor is not as high. The risk of the safety valve being deployed is minimized and any liquid refrigerant is driven from the compressor.

COMPRESSOR (B8444S ONLY)

Fig. 290: Compressor (B8444S Only)
Courtesy of VOLVO CARS CORPORATION

The compressor is mounted directly on the engine block and is driven by the engine crankshaft via the auxiliaries belt.

In the refrigerant circuit, the compressor is located between the evaporator and the condenser.

The compressor has variable displacement that is regulated by a replaceable solenoid, which is located on the underside of the compressor. The temperature sensor situated after the evaporator sends a signal to the Climate Control Module (CCM), which uses the signal to control the solenoid.

Compressors with variable displacement usually do not switch off during normal operation. The flow of refrigerant is continually adapted based on need. The compressor works between min. and max. displacement due to the following:

- the pistons are driven by a cam disc with a variable angle
- the angle is determined by springs if the compressor is disengaged
- if the compressor is engaged, the angle is determined by the pressure exerted on the top of the pistons (= intake pressure) and the bottom of the pistons (= pressure in the crankcase) during the intake phase
- the pressure on the bottom of the pistons (= in the crankcase) is regulated by a solenoid that is controlled

by the Climate Control Module (CCM).

If intake pressure is high, the compressor works to increase displacement.

- The solenoid opens and lowers the pressure in the crankcase. The counterpressure on the back of the pistons then reduces and the cam disc angle increases.
- The increased angle generates increased stroke, which causes a greater amount of refrigerant to be "sucked in" and a drop in intake pressure.

When intake pressure is low, the compressor works to reduce displacement.

- The valve closes and pressure in the crankcase increases. The pressure is built up by refrigerant that is led from the outlet side to the crankcase via a calibrated duct. The counterpressure on the back of the pistons then increases and the cam disc angle decreases.
- The decreased angle generated reduced stroke, which causes a smaller amount of refrigerant to be "sucked in" and an increase in intake pressure.

The compressor is also regulated by the A/C pressure sensor, which deactivates the system if pressure becomes too high.

The compressor is lubricated with specially developed refrigerant oil. This oil (synthetic PAG oil) is mixed with the refrigerant when the air conditioning system is in operation.

The compressor is the component of the climate control system with the largest mass. Thus, it takes the longest to warm up. In climates where the temperature varies greatly from night to day, it is often the compressor that is the system's coldest point each morning. Thus, all the refrigerant in the system makes its way to the compressor crankcase. Upon start, it takes 1-2 minutes for the refrigerant to evaporate. During this period, it may seem like the climate control system is not working.

MAGNETIC CLUTCH ASSEMBLY

Fig. 291: Identifying Magnetic Clutch Assembly
Courtesy of VOLVO CARS CORPORATION

1. Carrier disc
2. Shim discs
3. Spring ring
4. Pulley
5. Magnet coil.

The compressor is driven by the engine camshaft via the drive belt. As soon as the engine has started, the pulley (4) on the compressor drive shaft operates without hindrance.

Then the climate control system is switched on, the current passes through the magnetic coil (5), which is magnetized. This causes the carrier (1) on the compressor drive shaft to be pressed forward towards the pulley (4). The coupling is closed and the compressor rotates at the engine speed.

When the current to the magnetic coil is interrupted, the carrier disc (1) is released from the pulley (4) with the aid of return springs.

In order for the magnetic clutch to function correctly, the distance between the carrier disc (1) and the pulley (4) must be exactly correct. Shim discs (2) are therefore placed between them.

EXPANSION VALVE

Fig. 292: Expansion Valve
Courtesy of VOLVO CARS CORPORATION

1. Diaphragm
2. Valve housing
3. Refrigerant in liquid form from the receiver drier
4. Refrigerant in liquid form to the evaporator
5. Refrigerant in gas form from the evaporator to the compressor.

The expansion valve is mounted on the intake and outlet pipes of the evaporator. In the refrigerant circuit, it is

located on the high pressure side between the receiver drier and the evaporator.

The expansion valve is a pressure and temperature dependent flow regulator of the constriction type. At low cooling demand the amount of refrigerant is reduced by the valve closing. If the cooling demand increases the valve opens slightly to allow more refrigerant to the evaporator.

Systems with an expansion valve have a greater register than systems with a fixed choke because the amount of refrigerant can be better regulated to the cooling demand.

The expansion valve consists of a diaphragm (1) and a valve housing (2).

Cross section of the expansion valve

Fig. 293: Cross Section Of Expansion Valve
Courtesy of VOLVO CARS CORPORATION

1. Valve inlet from receiver drier
2. Valve slide
3. Valve outlet to compressor
4. Temperature sensor
5. Diaphragm (filled with refrigerant)
6. Diaphragm

7. Valve inlet from evaporator
8. Valve outlet to evaporator
9. Ball valve
10. Spring.

Liquid refrigerant comes from the receiver drier and flows through the valve inlet (1). The ball valve (9) mists the refrigerant before the refrigerant flows on through the valve outlet (8) and into the evaporator.

The ball valve opening is controlled by the temperature and pressure in the refrigerant gas coming out of the evaporator.

If for example the temperature of the refrigerant gas, coming from the evaporator in the expansion valve intake (7), increases the temperature sensor (4) and increases the temperature of the refrigerant in the diaphragm head.

The refrigerant in the diaphragm head expands and compresses the ball valve in the valve seat downwards using the diaphragm (6) and a valve slide (2) so that the valve seat opens. The flow of the refrigerant to the evaporator increases. The evaporator is cooled and the temperature of the refrigerant gas is reduced.

The ball valve closes as soon as the temperature in the evaporator falls and therefore the temperature of the refrigerant in the diaphragm head also falls.

EVAPORATOR

Fig. 294: Evaporator
Courtesy of VOLVO CARS CORPORATION

The evaporator is an air heated heat exchanger located in the distribution housing for the climate control system.

The surface of the evaporator is polyurethane coated to reduce bad odors. The polyurethane coating reduces the surface tension of the water and makes it easier for the water to run off.

The evaporator consists of pipe loops in which the refrigerant flows. The loops have flanges to increase the heat absorbing surface. The evaporator is inclined to make it easier for the condensation to run off. 10 - 11 liters of condensation are formed per hour. The condensation is led via a drainage house out of the distribution housing and down under the vehicle.

If one experiences bad odors when the vehicle is started, a workshop can activate a function which starts the blower fan a moment after the ignition key is moved to the 0 position. The fan blows the evaporator dry for a few minutes to prevent condensation and bad odors the next time the vehicle is used.

In the refrigerant circuit, the evaporator is located on the low pressure side between the expansion valve and the compressor.

In the evaporator there is a low pressure due to the expansion valve choke and the suction effect of the compressor. When the refrigerant enters the evaporator via the expansion valve, it expands and both its pressure and temperature lower.

When the warm air encounters the cold evaporator, the humidity condenses on the evaporator. The heat (energy) that is released during condensation is transferred to the refrigerant which evaporates. The temperature difference between the air and the refrigerant reduces. High humidity results in an increased need for cooling.

To obtain sufficient cooling capacity, the refrigerant's evaporation temperature must be considerably lower than the temperature desired in the passenger compartment. But to prevent the moisture that has condensed on the evaporator from freezing to ice, the air is not cooled below approximately +3 °C (at which stage the temperature of the refrigerant in the evaporator is approximately -3 °C).

There is a temperature sensor after the evaporator. The temperature sensor detects the temperature of the air that has passed through the evaporator. When the temperature is too low, the compressor is switched off. This is to prevent ice forming on the evaporator.

It is important that there is the correct amount of refrigerant in the climate control system.

- Too much refrigerant in the evaporator causes the refrigerant to heat up, but it only evaporates partially. This means that a smaller amount of heat is absorbed from the air, which results in reduced cooling capacity
- Too little refrigerant in the evaporator causes the refrigerant to evaporate and the vapor to overheat. This means that a smaller amount of heat is absorbed from the air, which results in reduced cooling capacity.

RECEIVER DRIER

Fig. 295: Identifying Receiver Drier
Courtesy of VOLVO CARS CORPORATION

1. Intake line from the condenser
2. Outlet line to expansion valve
3. Drying element
4. Liquid refrigerant
5. Riser.

The receiver drier is located to the right of the condenser in the engine compartment. In the refrigerant circuit, it is located on the high pressure side between the condenser and the expansion valve.

Liquid refrigerant passes at high pressure from the condenser through the intake pipe (1) and into the receiver drier. A drier element (3) separates any moisture from the refrigerant and filters any contaminants.

The refrigerant passes onwards through the riser (5) to the outlet line (2) and on to the expansion valve.

If the cooling system has been open (unplugged) for 10 minutes, or has leaked for some time, so that moisture may have entered the system the receiver drier must be replaced.

The receiver drier can only absorb a limited amount of moisture. If the system contains more moisture than the receiver drier can handle it may lead to icing which blocks the expansion valve.

A/C PRESSURE SENSOR

Fig. 296: A/C Pressure Sensor
Courtesy of VOLVO CARS CORPORATION

A linear pressure sensor is mounted directly on the receiver drier. The pressure sensor has an integrated measurement amplifier that generates an output voltage that is linear to the pressure.

The pressure sensor signal is used to control the following functions:

- the engine cooling fan (FC)
- deactivation of the compressor when pressure is too high
- deactivation of the compressor if the system has run dry of refrigerant.

CONDENSER (AIR COOLED HEAT EXCHANGER)

Fig. 297: Condenser (Air Cooled Heat Exchanger)
Courtesy of VOLVO CARS CORPORATION

The condenser is located in front of the engine radiator. The airflow and engine cooling fan (FC) blow air through the condenser. In the cooling system, the condenser is located on the high pressure side opposite the compressor and the receiver drier.

The condenser consists of pipe loops in which the refrigerant flows. The loops have flanges to increase the heat radiating surface.

When the refrigerant enters the condenser it is in gas form and has both high pressure and high temperature. In the condenser the hot refrigerant loses some of its heat to the surrounding cooler air. The refrigerant then condenses and changes into liquid form. The amount of heat given off = the amount of heat taken up in the evaporator + the amount of heat supplied by the compressor. In order to supply sufficient cooling capacity, the condensation temperature of the refrigerant must be greater than the temperature of the outside air.

SERVICE VALVES

Fig. 298: Identifying Service Valves
Courtesy of VOLVO CARS CORPORATION

1. The service valve for draining, vacuum pumping and filling with refrigerant
2. Service valve for draining and vacuum pumping.

One service valve is located on the low pressure side and one service valve is located on the high pressure side. The valves are different sizes. This is to avoid incorrect connection.

CAUTION: Filling with refrigerant must only be carried out on the high-pressure side to prevent the risk of liquid refrigerant in the compressor.

HOSES, PIPES

All connections, apart from those for the expansion valve and condenser, have double O-rings as a seal. The connections for the expansion valve and condenser have single O-rings.

The O-rings are manufactured in a specially developed material (HNBR = hydrated nitrile rubber).

AIR DISTRIBUTION SYSTEM

GENERAL INFORMATION

Fig. 299: Air Distribution System Components
Courtesy of VOLVO CARS CORPORATION

The air distribution system consists of:

- climate control system:
  - blower fan
  - damper
  - filter
  - recirculation throttle.
- air ducts
- vents.

Dampers control the outgoing air to:

- defroster
- the dashboard vents
- the floor outlets
- the B post vents.

Fresh air enters the climate control system through the fresh air intake under the plenum chamber.

The fresh air intake is located:

- on the right-hand side

Air enters the climate control system and is distributed by a large number of air vents to the passenger compartment. After circulating, the air leaves the passenger compartment via the evacuation valves in the cargo compartment.

THE DAMPERS

Fig. 300: Identifying Temperature Damper Assembly
Courtesy of VOLVO CARS CORPORATION

1. Temperature damper for controlling the heater element

2. Temperature damper upstream of heating element
3. Temperature damper downstream of heating element
4. Defroster damper
5. Ventilation damper
6. Floor damper
7. Fresh air damper
8. Recirculation damper.

Dampers controlled by damper motors are located in the climate control system.

- Electronic climate control (ECC) has five damper motors
- Manual climate control (MCC) has four damper motors.

There are eleven different dampers controlling the air flow of the climate control unit:

- Six temperature dampers for mixing hot and cold air. Three for the left hand side and three for the right hand side. On each side one damper (2) is installed before and one damper (3) installed after the heater pad. Together (1) and (2) control the amount of air to be heated and (3) guides the warm air to the correct vent
- A floor vent for guiding the airflow to the front and rear of the floor
- A defroster damper for guiding the airflow to the front windshield and side windows.

NOTE: Electronic climate control (ECC) has a separate damper motor for the defroster damper.

- A ventilation shutter for guiding the airflow to the dashboard and B post
- A fresh air damper for controlling the flow of external air into the climate control system
- A recirculation damper for controlling the flow of the air in the passenger compartment back into the climate control system.

By changing the direction of the dampers in the climate control system, air is directed through the various air ducts out to the passenger compartment.

The temperature is regulated by mixing hot and cold air. The temperature dampers on the right and left sides are controlled by a damper motor each. This makes it possible to have different temperatures on the driver's side and the passenger side.

The dampers are regulated proportionally to ensure that the passenger compartment achieves the selected temperature.

The fresh air damper is speed controlled, which means that the damper reduces the size of the hole to the air inlet the higher the vehicle speed. At speeds above 60 km/h the fresh air damper closes successively. At speeds above 120 km/h the fresh air damper is nearly completely closed. The speed control of the fresh air is to keep the airflow in the passenger compartment constant, irrespective of the speed of the vehicle.

RECIRCULATION

There are two ways for the ventilation system to draw in air:

- fresh air enters through the fresh air intake in the climate control system under the plenum chamber
- recirculated air from the passenger compartment.

DASHBOARD VENTS

Fig. 301: Dashboard Vents
Courtesy of VOLVO CARS CORPORATION

There are four vents on the dashboard. Two are located in the middle at the front and one on either side.

The air flow can be regulated, fully closed or steered in the required direction using a damper. The damper is controlled with the thumb wheel located on the side of the vent. (See illustration).

DEFROSTER VENTS

There are six defroster vents, two for the windshield, two for the front side windows and two for the rear side windows. The two for the windshield are designed so that the majority of the air is directed up against the windshield. The remaining air trickles out at the bottom edge of the windshield to help keep the windshield wipers free of ice.

The air ducts to the front side window defrosters are a continuation of the windshield ducts.

The air ducts to the rear side windows go via the floor to the B posts. The air ducts are a continuation of the windshield ducts.

The defroster vents in the B posts can be adjusted by the rear seat passengers.

The seven seat XC90 has two additional defroster vents, one in each C post. The air to the two additional defroster vents comes from the XC90s rear climate control.

FLOOR VENTS

There are four air vents in the floor (seven seat XC90 has six air vents).

Two are positioned under the respective soundproofing panel, one on each side of the center console. The other two are located one under each front seat and face backwards.

Seven seat XC90s two additional floor air vents are located on the left and right hand sides below the center row of seats.

EVACUATION VALVES

Fig. 302: Evacuation Valves
Courtesy of VOLVO CARS CORPORATION

In 4-door vehicles, the air vents are located at the edge between the parcel shelf and the rear windshield. The air goes from here through the cargo compartment and on out through the air vents behind the rear bumper.

In 5-door vehicles, the air passes directly out through the air vents in the cargo compartment.

There are rubber flaps in the air vents. The flaps open when the air pressure is higher in the passenger compartment that outside. When the air pressure is the same on the inside and the outside, the flaps close. This prevents water and air (odors, dust and exhausts fumes) from penetrating the passenger compartment.

AIR CONDITIONING (A/C) REAR, SEVEN SEAT XC90 (OPTION)

Fig. 303: Air Conditioning (A/C) Rear, Seven Seat XC90
Courtesy of VOLVO CARS CORPORATION

1. Fan motor
2. Power unit
3. Housing rear climate control unit
4. Pipe rear climate control unit
5. Switch, fan speed
6. Air duct
7. Evaporator
8. Expansion valve
9. Drain hose.

As an option, it is possible to have additional air conditioning in the rear of the seven seat XC90. The air conditioning unit is located inside the panel on the left hand side of the cargo compartment panels. The front and rear air conditioning refrigerant circuits are connected in parallel. The rear air conditioning is connected via a connector on the firewall.

The connection between the rear and front air conditioning units is via pipes and rubber hoses inside the passenger compartment. The fan (1) is operated using a control (5) placed on a panel at the rear of the passenger compartment.

The compressor, condenser and receiver drier are used together by the front and rear air conditioning units.

A T-connection is located on the high-pressure side in the engine compartment between the receiver drier and the expansion valve. A T-connection for refrigerant, with high pressure, from the front climate control unit to the rear climate control unit.

The refrigerant is sprayed into the rear evaporator using the rear expansion valve. Then the refrigerant is routed at low pressure back to the front air conditioning unit. The return routing is connected to the front cooling system using a T-connection located between the expansion valve and the compressor on the low pressure side of the engine compartment.

FUNCTION

AIR CONDITIONING

See:**AIR CONDITIONING**

AIR DISTRIBUTION SYSTEM

See: **AIR DISTRIBUTION SYSTEM**

BLOWER FAN

Fig. 304: Blower Fan
Courtesy of VOLVO CARS CORPORATION

The blower fan provides the airflow through the vehicle.

The blower fan must be operating before the climate control system can be engaged.

The blower fan switches off when the vehicle speed is approximately 160 km/h.

FILTER

Fig. 305: Filter
Courtesy of VOLVO CARS CORPORATION

The particle filter cleans the air of particles such as dust and pollen, which would otherwise pass through the air intake into the passenger compartment.

The multi-filter has the same function as the particle filter, but also neutralizes unpleasant smells and keeps the air as free from gases as possible. In vehicles that have the multi-filter, known as the air quality system (AQS), there is also an outside air sensor that ensures that the recirculation closes in the event that the content of gases in the outside air increases. This increases the service life of the multi-filter.

ADDITIONAL HEATER/PARKING HEATER

Fig. 306: Additional Heater And Parking Heater
Courtesy of VOLVO CARS CORPORATION

The additional heater/parking heater produces heat by burning gasoline. The heat is distributed via the engine cooling system to the heat exchanger and on out into passenger compartment.

When the engine is running, the additional heater can provide extra heat to the passenger compartment in the event that the engine is unable to provide sufficient heat. When the engine is not running, the parking heater can heat the passenger compartment (and the engine). This function can be started directly or using a timer.

AIR CONDITIONING

GENERAL INFORMATION

Fig. 307: Climate Control System
Courtesy of VOLVO CARS CORPORATION

The air conditioning only functions at ambient temperatures above 0 °C. At temperatures lower than this, the pressure in the system is too low and the compressor is never engaged. This setting is made to prevent ice building up on the evaporator.

The air conditioning only functions when the engine is running. The air conditioning functions regardless of engine speed (RPM) and vehicle speed. The compressor is dependent on the engine speed, the higher the engine speed the more cooling that can be provided.

The blower fan must be operating before the climate control system can be engaged.

The air conditioning system has only two positions, off and on. If it is too cold in the passenger compartment, the temperature can be controlled with the normal heat and blower fan controls.

Air conditioning is based on the same principle as that used in refrigerators.

The rear climate control unit in the seven seat XC90 supplies the passengers in the third row of seats with cooled air. For the rear climate control system to function the rear climate control system blower fan motor must be running and the front climate control system must be switched on.

REFRIGERANT

Fig. 308: Identifying Principle Sketch Of Climate Control System
Courtesy of VOLVO CARS CORPORATION

1. Compressor
2. Condenser
3. Engine cooling fan (FC)
4. Receiver drier
5. Expansion valve
6. Evaporator
7. Blower fan.

Explanation:

A - High pressure, warm fluid

B - Low pressure, cold fluid

C - Low pressure, cold gas

D - High pressure, warm gas

Dark arrow - Warm air

Light arrow - Cold air

By allowing the refrigerant to circulate in the closed system and changing the pressure and volume it will change temperature and boil (evaporate). At the pressure found in the system, approximately 170 - 320 kPa (1.7 - 3.2 bar), the refrigerant boils at approximately 0 °C to +4 °C.

A condition of the refrigerant boiling is that the heat is accessible. This heat is taken from the air around the

evaporator (6) where boiling occurs. When the heat is taken up by the refrigerant the surrounding air becomes cooler. It is this cooled air that is blown into the passenger compartment by the climate control system blower fan (7). The heat taken up by the refrigerant in the evaporator (6) is transported out to the engine compartment, where it is transferred to the air by the condenser (2). The condenser is cooled by the airflow and the engine cooling fan (FC) (3).

COMPRESSOR

Fig. 309: Compressor (Not B8444S)
Courtesy of VOLVO CARS CORPORATION

The task of the compressor is to:

- draw gaseous refrigerant from the evaporator
- compress the gas thereby increasing its pressure and temperature
- expel the gas with high pressure and high temperature to the condenser.

The compressor takes in cold refrigerant gas from the evaporator on the intake side through the low pressure connection. In ideal conditions, the compressor compresses the refrigerant from approximately 200 kPa (2 bar) to between 1.2 MPa and 2.1 MPa (12 and 21 bar). During the process, the refrigerant heats up from 0 °C to between 70 °C and 110 °C. These pressure and temperature values apply when the system is operating under optimal conditions.

The relief valve, located on the rear section of the compressor, functions as an additional safety device. The valve opens and releases refrigerant when the pressure in the system is too high. The valve then shuts again when the pressure has returned to normal. The temperature of refrigerant gas can reach as high as 125 °C.

The compressor can only compress gases, as liquid would damage the compressor.

EXPANSION VALVE

Fig. 310: Expansion Valve
Courtesy of VOLVO CARS CORPORATION

The expansion valve checks the refrigerant flow in the evaporator in relation to the temperature and pressure. The expansion valve gives an even temperature control because the amount of refrigerant is controlled as necessary.

EVAPORATOR

Fig. 311: Evaporator
Courtesy of VOLVO CARS CORPORATION

The task of the evaporator is to cool and dry the air.

The refrigerant (the volume that is measured by the expansion valve) is sprayed into the evaporator. As soon as the refrigerant enters the cooling pipes, it evaporates due to the drop in pressure. During this process, heat is also extracted from the cooling pipes. The cooling pipes and the entire evaporator cool immediately. The refrigerant gas is then drawn out using the compressor.

The airflow is routed past the evaporator and is cooled and dried, and then forwarded to the passenger compartment via the air distribution ducts.

When the air entering the passenger compartment encounters the cold evaporator, the humidity in the air condenses on the evaporator. The water drains out under the vehicle via a drain hose. In the event of high

humidity, this may be considerable quantities of water, which is often mistaken for a water leak from the engine for example.

RECEIVER DRIER

Fig. 312: Identifying Receiver Drier
Courtesy of VOLVO CARS CORPORATION

The task of the receiver drier is to:

- function as a filter, taking up and binding moisture (water) found in the system
- function as a storage container for leak detection agent.

The leak detection dye mixes with the oil. When a leak occurs, it is possible to locate the leak with UV light.

CONDENSER (AIR COOLED HEAT EXCHANGER)

Fig. 313: Condenser (Air Cooled Heat Exchanger)
Courtesy of VOLVO CARS CORPORATION

The task of the condenser is to cool, so converting the hot, gaseous refrigerant to a liquid.

The compressor pumps in hot refrigerant gas under high pressure. The gas has a temperature of between 70 and 110 °C in the intake on top of the condenser. When the hot gas flows through the pipe loop, it is cooled down

and condensed. The heat that is removed from the gas during this process is transferred to the surrounding air. The engine cooling fan (FC), which is the same fan used by the engine cooling system, increases the airflow through the condenser. The air flow increases the transfer of heat from the refrigerant to the outside air.

The engine cooling fan (FC) is controlled by the linear pressure sensor (high-pressure and safety valve), located on the drier, via the engine control module (ECM) and via the control module for the engine cooling fan (FC). The engine cooling fan (FC) is also controlled by the engine coolant temperature (ECT).

SERVICE VALVES

Fig. 314: Identifying Service Valves
Courtesy of VOLVO CARS CORPORATION

1. The service valve for draining, vacuum pumping and filling with refrigerant
2. Service valve for draining and vacuum pumping.

The service valves are used to:

- check the system through manometer connections
- drain the system of refrigerant
- vacuum pumping
- filling with refrigerant, high-pressure side only (1).

CAUTION: Filling with refrigerant must only be carried out on the high-pressure side to prevent the risk of liquid refrigerant in the compressor.

AIR DISTRIBUTION SYSTEM

GENERAL INFORMATION

Fig. 315: Air Distribution System
Courtesy of VOLVO CARS CORPORATION

The air distribution system distributes the air to the passenger compartment. It is used jointly by the heating system and the cooling system in the climate control system. The blower fan draws air into the system. Fresh air enters through the fresh air intake in the distribution housing under the plenum chamber.

The air passes through the filter and the evaporator, past the temperature damper and possibly though the heat exchanger, before being released into the passenger compartment through the vents.

The temperature of the air from all the air vents can be controlled separately for the right or left hand sides.

After circulating, the air disappears out of the passenger compartment though air vents at the rear of the vehicle.

RECIRCULATION

The recirculation damper regulates the amount of incoming fresh air. The recirculation function makes it

possible to prevent outside air from entering the passenger compartment, for example when the ambient air is contaminated with exhaust fumes, smoke, etc. This function can also be used for rapid heating or cooling of the passenger compartment.

If the recirculation function is used for an extended period, the air humidity in the passenger compartment increases. This is because of the humidity of the expelled breath of the passengers. This can result in mist on the windows. The recirculation function has a timer function to eliminate the risk of misting.

When the controls are in the Maximum cooling position all the air is taken from the passenger compartment. This produces more rapid cooling of the passenger compartment air.

In vehicles with an air quality system (AQS), the transition to recirculation takes place automatically if the level of contaminants in the outside air increases, when the system is in the AUTO mode.

DEFROSTER VENTS

Mist forms easily on the windows in cold, damp weather. The defroster vents release air towards the front and side windows. The air flow removes the mist that forms. As the air is dry, the airflow also prevents moist air from the passenger compartment reaching the glass, so countering misting. The air conditioning contributes significantly to these functions by dehumidifying the air at temperatures above 0 °C.

The defroster function, for the electronic climate control system (ECC), automatically sets the climate control system for the best defrosting of windshields.

EVACUATION VALVES

Fig. 316: Evacuation Valves
Courtesy of VOLVO CARS CORPORATION

The evacuation valves are used to even out the pressure in the passenger compartment.

The rubber dampers in the evacuation valves open when the air pressure is slightly higher in the passenger compartment than outside. When the air pressure is the same on the inside and the outside, the rubber dampers close. This prevents water and air (odors, dust and exhausts fumes) from penetrating the passenger compartment.

NOTE: The evacuation valves must not be blocked, this will impair the function of the climate control system.

OVERVIEW

Fig. 317: Climate Control System
Courtesy of VOLVO CARS CORPORATION

The climate control system is no longer a luxury item in modern vehicles. It has instead become a factor for active safety, and can now be considered part of the safety equipment in the vehicle.

The correct temperature in the passenger compartment increases safety.

It is well documented that the human performance abilities are reduced in heat. Research carried out in traffic and in a normal vehicle demonstrated that when the passenger compartment temperature was increased from 21 to 27 °C:

- the risk of the driver missing important traffic information (hazard warnings, traffic signals, signs etc.) increased by 50 %
- the driver reaction times were 22 % slower.

With an air conditioning system in the vehicle, car travel is both more comfortable and safer.

A climate control system provides increased comfort by:

- cooling the air in the event of high temperatures in the surrounding air or in warm, sunny conditions
- warming the air in the event of low temperatures
- dehumidifying the air
- filtering the air.

The relative humidity of the air is extremely important for our well-being. We perceive a relative humidity of 30-60 % to be comfortable, as the moisture that is given off by the human body can easily be absorbed by the surrounding air.

If the humidity exceeds 75 %, we perceive it to be oppressive and uncomfortable in warm weather, as the air cannot absorb much more moisture. For this reason, the climate control system is designed to regulate both temperature and air humidity.

The vehicle is equipped with either:

Fig. 318: Electronic Climate Control
Courtesy of VOLVO CARS CORPORATION

Electronic climate control, ECC

ECC is a fully automatic climate control system that has the option of manual settings.

Fig. 319: Manual Climate Control
Courtesy of VOLVO CARS CORPORATION

Manual climate control, MCC

MCC is a manual climate control system.

The climate control system comprises a heater and an air conditioner. These are combined in the distribution housing to form a single unit with a shared ventilation system for distributing heating and cooling in the passenger compartment.

The system mixes the air, i. e. hot and cold air are mixed to achieve the desired temperature. One advantage of this is that the temperature in the passenger compartment can be changed quickly if required. Another advantage is that the ECC system compensates extremely quickly when the external conditions change.

The seven seat XC90 has an extra air conditioning unit in the rear. The additional air conditioning unit is located inside the panel on the left hand side of the cargo compartment panel.

The climate control module (CCM) controls the climate control system and the buttons in the dashboard environment panel.

The climate control system also includes a number of sensors.

When the engine is running, the additional heater can provide extra heat to the passenger compartment and the

engine. The parking heater heats up the passenger compartment and the engine when the engine is not running. This function can be started directly or by using a timer.

Gasoline cars may have an additional heater/parking heater as an option.

ACCESSORIES AND BODY, CAB

Miscellaneous - Design and Function

REAR SEAT ENTERTAINMENT SYSTEM (RSE), GENERATION 4.3 (2009-2012)

SYSTEM OVERVIEW

REAR SEAT ENTERTAINMENT SYSTEM

XC90

Fig. 1: Rear Seat Entertainment System Components
Courtesy of VOLVO CARS CORPORATION

1.	Screen, head restraint (16/81A, B)	6.	Fuse holder and fuse for the TV receiver (only if the TV receiver is installed)
2.	DVD-player with integrated Rear seat entertainment module (RSE) (16/109)	7.	Antennas (left 16/69, right 16/70) (two) for the digital TV receiver (only if the TV receiver is installed).
3.	AUX-input (16/123.2) (for XC90 17/40.1)	8.	Headphones (two)
4.	AV-panel (16/123.3)	9.	Remote control

5.	Digital TV receiver (DVB-T) (16/36) (if the option is installed)		

The rear seat entertainment system is a mobile entertainment system to keep rear seat passengers occupied and entertained with video games digital TV transmissions or movies.

The system is fully integrated in the car and has two separately controlled, high-resolution 8-inch screens mounted in the head restraints.

The Rear seat entertainment module (RSE) is integrated in the DVD player and can receive signals from up to three AV inputs or a digital TV receiver and can provide video to two separately controlled screens. The module can also provide output signals to an external screen.

The control module/DVD-player is installed in the storage compartment in the center console.

The following media formats can be played by the DVD player:

- DVD-R/+R
- DVD-RW/+RW
- CD-R and CD-RW
- CDDA
- HDCD

The following information formats can be played:

- DVD
- DVD Audio
- VCD
- SVCD
- DivX
- WMV
- Audio CD
- Kodak photo CD
- MP3
- MP3 Pro
- playlists in M3U format
- WMA Sound.

Formats such as THX and DolbyDigital are also supported. Only stereo signals of this audio format are reproduced.

A connection panel with AV inputs is installed behind the cover on the centre console, in XC90 it is located at the rear of the centre console. Other audio and video sources can be connected to the system via this, for

example, video cameras, game consoles or portable DVD and CD players.

The system includes two pairs of wireless headphones. Audio is transferred to the headphones via infrared signals (IR) from the transmitters in each screen.

Audio can also be played in the vehicle's ordinary speakers via the connection from Rear seat entertainment module (RSE) to Integrated Audio Module (IAM).

The vehicle's ordinary AUX input is located in the storage tray between the front seats where a portable CD or media player can be connected. The Rear seat entertainment module (RSE) is connected to the AUX input with left and right audio signals. Select "AUX" as the audio source on the audio panel in order for this audio to be heard.

As an option there is a digital TV receiver (DVB-T). This receives digital terrestrial transmitted TV channels, converts them and sends them to the Rear seat entertainment module (RSE). In order to view paid-by-view channels the receiver must be supplemented with a subscription/program card.

The system is controlled using an infrared (IR) remote control, which can be used to control the screens, DVD player and TV receiver.

SIGNALS

The following tables summarize input and output signals to the units in the system for rear seat entertainment.

NOTE: The CAN communication given here is only a private CAN between the control module and the screens.

REAR SEAT ENTERTAINMENT MODULE (RSE)/DVD-PLAYER (16/109)

Input signals:	Output signals:
Directly connected: • Commands from remote control via head restraint screens (16/81A, B). • Audio/video signals from AV-panel (16/123.3). • Digital TV receiver (16/36), audio and video signals.	**Directly connected:** • Screen, head restraint (16/81A, B), audio and video signals. • Screen, head restraint (16/81A, B), power supply and ground terminal. • AUX input (16/123.2) (for XC90 17/40.1), audio and video signals to the vehicle's audio system. • Digital TV receiver (16/36), wake-up signal and commands from the remote control.
Via Controller Area Network (CAN) communication: • Communication with the screens (16/81A, B), communication signals, temperature signal.	**Via Controller Area Network (CAN) communication:** • Communication with screens (16/81A, B).

SCREEN, (CIRCUIT BOARD) HEAD RESTRAINT (16/81A, B)

Input signals:	Output signals:
Wireless communication : • IR signals from the remote control.	**Wireless communication :** • IR signals for audio to wireless headphones.
Directly connected: • Rear seat entertainment module /DVD-player, audio and video signals. • Rear seat entertainment module /DVD-player, wake-up signal. • Rear seat entertainment module /DVD-player, voltage feed and ground connection.	**Directly connected:** • Rear seat entertainment module /DVD player, command from remote control.
Via Controller Area Network communication: • Rear seat entertainment module /DVD-player, control signals.	**Via Controller Area Network communication:** • Rear seat entertainment module /DVD player, communication signals, temperature signal.

WIRELESS HEADPHONES

Input signals:	Output signals:
Wireless communication : • Screen, head restraint, IR signals from transmitter in screen.	**Wireless communication :** -

TV RECEIVER

Input signals:	Output signals:
Directly connected: • Rear seat entertainment module /DVD player, command from remote control. • Rear seat entertainment module /DVD-player, wake-up signal.	**Directly connected:** • Rear seat entertainment module /DVD-player, audio and video signals.

REAR SEAT ENTERTAINMENT SYSTEM, M&D

DESIGN

DVD DEVICE

Fig. 2: Identifying Screen, Head Restraint
Courtesy of VOLVO CARS CORPORATION

The system consists of two DVD devices with DVD player integrated in the screens. To access the DVD player, lift the button mounting at the lower edge of the screen. Discs are inserted via a feed slot in the DVD player.

Two DVD devices are included in the original installation kit: a and a. A DVD device is available as a replacement part. Select DVD device via the remote control. The screen is recoded via the service menu.

The DVD unit's mechanism is designed to withstand shaking to prevent the image or audio quality from being distorted during playback.

The DVD device is region coded, which can be changed using a security code. The screen is designed for PAL and NTSC image display.

The DVD device interprets and performs the commands that are specified by the user via the system's remote control or via the screen's front panel.

The DVD device has memory handling to remember where, for example, in a film different power cut-offs occurred.

The system is 15-supplied, which means that the ignition must be on to activate the system. When the ignition is switched off, the system shuts down automatically. There is also a voltage sensor that switches off the system when the battery has a low voltage level. Depending on which the system is set to, the screen will react differently when the DVD device is switched ON/OFF. Coding of can be done via a service menu.

The audio to the car's stereo can be switched off or on regardless of the setting of the headsets. However, if the customer connects an external source to the car's own A/V input, audio cannot be played-back from the system for rear seat entertainment in the car's stereo.

To select external audio and image sources there is a separate A/V input for each DVD unit. The A/V input is on the lower edge on the right-hand corner of the screen. The system for rear seat entertainment also contains a extension cable of the RCA type for the connection of external equipment: DVD or CD player, iPod®, MP3 player, video camera, VHS video or games console.

Connecting external equipment

- Yellow socket: Video signal
- White socket: Left channel for audio
- Red socket: Right channel for audio

The following media formats can be played by the DVD player:

- DVD-R/+R
- DVD-RW/+RW
- CD-R/+R
- CD-RW/+RW

The following information formats can be played:

- DVD - Video, Audio
- CD Digital Audio
- Super Audio CD
- MP3 Audio CD/MP3 ID3 Tags ISO 96660
- VCD
- WMV
- SVCD
- DivX/MPEG-4
- Windows Media Audio
- OGG multimedia format

Formats such as THX and DolbyDigital are also supported. Only stereo signals of this audio format are reproduced.

To easily check if the DVD device is powered and grounded, switch the ignition on, the background lighting on the screen's button should then illuminate. The system for rear seat entertainment is activated by pressing the button, the Volvo emblem then appears on the screen. The DVD devices and are controlled independently via the screen's front panel or via the system's remote control.

A/V INPUT

Fig. 3: Locating A/V Input
Courtesy of VOLVO CARS CORPORATION

The system has an A/V input that enables the connection of external media sources: iPod®, MP3 player, video camera or games console. The A/V input is on the lower edge on the right-hand corner of the screen.

SCREEN, HEAD RESTRAINT

Fig. 4: Identifying Screen, Head Restraint
Courtesy of VOLVO CARS CORPORATION

The screen on each of the headrests is a 16:9 format, 7 inch TFT LCD screen and has a 120 degree horizontal viewing angle. The screen is manually adjustable to minimise the risk of reflections and mirroring in harsh light conditions. The top of the screen has 4 LEDS for transmitting and receiving infrared signals from remote controls and headsets.

HEADPHONES

Fig. 5: Locating Corded Headset Socket
Courtesy of VOLVO CARS CORPORATION

The wireless headsets can be used by passengers in the rear seat. Standard audio is transferred via infrared signals to the headsets in two-channel stereo format. The headsets are powered by a battery which is located in the left headset under a cover. The headsets are activated by a button on one side of the headsets. The volume for each headset is adjusted via a volume control. Selection of audio source, DRIVER or PASSENGER, is made via control button: CH A and CH B.

Corded headsets can also be connected to the system, one to each screen. The socket is located at the lower edge of the screen on the left corner.

REMOTE CONTROL

Fig. 6: Identifying Remote Control
Courtesy of VOLVO CARS CORPORATION

The remote control can be used to switch between different audio and/or video inputs in the system:

- DVD device, audio/video
- A/V input, audio or audio/video

The remote controls can be used to navigate the menu system, system menu, DVD menu and the service menu.

The remote control uses infrared signals to transfer the command to the system. The remote control uses two AAA batteries, installed under a cover on the rear of the control.

CHANGING THE REGION CODE IN THE DVD DEVICE

Fig. 7: The Region Code Can Be Changed Up To 5 Times
Courtesy of VOLVO CARS CORPORATION

The region coding means that only discs that correspond with the set region in the DVD device can be played. Preselected region code is region code 1. The region code in the DVD device can be changed up to 5 times. After that, the set region is then locked and cannot be changed.

Region codes:

1. USA, Canada, and Bermuda.
2. Europe including Armenia, Georgia, Azerbaijan, Egypt, Iran, Japan, Lesotho, South Africa, Swaziland, French Guyana, and Greenland.
3. South East Asia, Hong Kong, Macao, South Korea, and Taiwan.
4. Australia, Oceania, Mexico, Central America, and South America.
5. Russia, South Asia, India, Mongolia, North Korea, and Africa.
6. China excluding Hong Kong and Macao.

NOTE: **Warranty repairs due to locked region on the DVD device will not be approved. Region code changes to the region in which the vehicle will be used can only to be done at the workshop. The security code is not to be given to the customer. Region code 0 is not used.**

Do as follows to open the menu for region code change:

1. Turn on the ignition.
2. Activating the system for rear seat entertainment.

   NOTE: **There must not be a disc in the DVD player.**

3. Press or on the remote control depending on which DVD device is to be coded.
4. Point the remote control at the DVD device to be coded and press: 7, 7, 7 and then the button.
5. Select the region code that applies to the relevant vehicle and press.
6. Use the **RIGHT** respectively **LEFT** arrow to select region. Then press.
7. Press to exit the menu.
8. Deactivating the system for rear seat entertainment.

Perform the same procedure for both the right and left screens separately.

SERVICE MENU FOR CHANGING POWER MODE

There are three different in the system that define how the system is to interact in switching the system ON/off. The system is set to as default, and this should not be changed unless requested by the customer.

Short description of the various :

- : The DVD device is automatically activated when the ignition is switched on.
- : The DVD device is automatically set to standby mode the next time the ignition is switched on after the power has been cut.
- : The DVD device is automatically activated if, in the last operating cycle, it was activated, and deactivated if, in the last operating cycle, it was deactivated, the next time the ignition is switched on.

Do as follows to open the menu for changing :

1. Turn on the ignition.
2. Activating the system for rear seat entertainment.

   NOTE: **There must not be a disc in the DVD player.**

3. Press or on the remote control depending on which DVD device is to be coded.

   NOTE: **Ensure that only the DVD unit to be coded is active.**

4. Point the remote control at the DVD device to be coded and press the following sequence: **UP** , **RIGHT** , **LEFT** , **DOWN** and then.
5. Select the applicable coding for the relevant DVD device by scrolling the menu with the **RIGHT** arrow. Then press to confirm and exit the menu.
6. Deactivating the system for rear seat entertainment.

SERVICE MENU FOR CHANGING THE DRIVER/PASSENGER SETTINGS

All replacement parts of the DVD device are coded for the driver's side). To install a DVD device on the passenger side so that it corresponds with the remote control it must be recoded to.

Do as follows to open the menu for changing the / settings:

1. Turn on the ignition.
2. Activating the system for rear seat entertainment.

   NOTE: There must not be a disc in the DVD player.

3. Press or on the remote control depending on which DVD device is to be coded.

   NOTE: Ensure that only the DVD unit to be coded is active.

4. Point the remote control at the DVD device to be coded and press the following sequence: **UP** , **RIGHT** , **LEFT** , **DOWN** and then.
5. Select the applicable coding for the relevant DVD device by scrolling the menu with the **LEFT** arrow. Then press to confirm and exit the menu.
6. Deactivating the system for rear seat entertainment.

DIAGNOSTIC FUNCTIONS

FAULT-TRACING INFORMATION

The system for rear seat entertainment does not contain any diagnostic functions and is not connected to the vehicle's communication network. This means that no DTCs can be read out from the DVD device. All fault tracing must be performed via symptom fault tracings.

FUNCTION

Fig. 8: Identifying Rear Seat Entertainment System Cmponents
Courtesy of VOLVO CARS CORPORATION

The system can be activated either with the button on the screen or with the button on the remote control. This is done separately for the right, respectively left screens. If the system is to be activated with the remote control, the ignition must be on and the remote control pointed at the screen.

SYSTEM START-UP

When the ignition is switched on, the lighting in the screen's -button and the system become set to standby mode. When the button is pressed in, the system is activated and an image with the Volvo emblem appears.

The remote control can be used to activate/deactivate the system and to navigate the menu system.

- Switch between audio/video source.
- Image adjustment.
- Audio settings.
- Language selection for on-screen instructions.

An internal memory saves the language selection and the current audio and video settings. These settings are loaded upon start-up with the exception of volume level, which is set to low as standard.

When a CD/DVD is inserted, playback starts automatically if the CD/DVD does not have a menu. DVD playback can be resumed from a standby mode, e. g. if the ignition is switched off during the playback of a film. In this case, playback continues from the last point when the ignition is switched back on, after the system has been reactivated. To insert a disc, the screen must first be folded out.

TEST SEQUENCE

Procedure	Expected result	Remarks
1. Insert the key and turn on the ignition.	The lighting in the screen's button illuminates and the system is set to standby mode.	

2. Activate the DVD device on the driver's side using the remote control by first pressing and then.	Only the DVD device on the driver's side is activated and the Volvo emblem appears on the screen.	If the DVD device on the passenger side is activated, the DVD device must be recoded. See: **DESIGN**- Service menu for changing DRIVER/PASSENGER settings
3. Activate the DVD device on the passenger side using the remote control by first pressing and then.	Only the DVD device on the passenger side is activated and the Volvo emblem appears on the screen.	If the DVD device on the driver's side is activated, the DVD device must be recoded. See: **DESIGN**- Service menu for changing DRIVER/PASSENGER settings
4. Ensure that the correct DVD region is coded in. This is done manually on each DVD device.		See: **DESIGN**- Changing the region code in the DVD device
5. Ensure that the system is in standby and then switch off the ignition.		

HEADPHONES

Fig. 9: Identifying Headsets
Courtesy of VOLVO CARS CORPORATION

Two headsets are supplied with the system as standard. The number of headsets that can be used is unlimited as long as they are within range of the IR transmitters. Transfer of audio between DVD devices and the wireless headsets is via infrared signals. There must not be any obstacles blocking the transmitter, which is located at the top of the screen, and the receivers, which are on the side of the headsets. If the path is blocked, the signal will be interrupted and the sound quality affected. Select sound source, or, via control button: and (channel B).

The headsets are activated using a button on one side of the headsets. The headsets switch off automatically if an IR signal is not received within 3-4 minutes.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 10: Identifying Rear Seat Entertainment System Cmponents
Courtesy of VOLVO CARS CORPORATION

The rear seat entertainment system is a mobile entertainment system integrated in the headrests for keeping passengers in the rear seats occupied and entertained with video games or movies.

The system consists of two brilliant 7-inch, 16:9 format LCD screens. The screens can be adjusted manually to minimise the risk of reflections and mirroring in strong light conditions. The DVD players are integrated in the screens. Media discs are loaded from underneath, which reduces the risk of small objects being inserted into the DVD player. The system is equipped with AUX inputs, which make it possible to connect external media sources: iPod®, MP3 player, video camera or games console. The system also contains two pairs of wireless headphones and a wireless remote control. The DVD devices have been thoroughly tested and meet Volvo's high demands on safety.

The following media formats can be played by the DVD player:

- DVD-R/+R
- DVD-RW/+RW
- CD-R/+R
- CD-RW/+RW

The following information formats can be played:

- DVD - Video, Audio (Single/Dual layer)
- CD Digital Audio
- Super Audio CD (SACD)
- MP3 Audio CD/MP3 ID3 Tags ISO 96660
- VCD (Video CD)
- WMV
- SVCD (Super VCD)
- DivX/MPEG-4

- Windows Media Audio (WMA)
- OGG multimedia format

Formats such as THX and DolbyDigital are also supported. Only stereo signals of this audio format are reproduced.

SIGNALS

The tables below include the in and output signals for the DVD devices in the system for rear seat entertainment.

DVD DEVICE

Input signals:	Output signals:
Wireless communication (IR): • Remote control	**Wireless communication (IR):** • IR signals to wireless headphones
Directly connected: • Ignition on/off (supply for the system). • Internal A/V input from corresponding DVD device.	**Directly connected:** • Internal A/V output to corresponding DVD device. • Connecting to the car's stereo. • Wireless headsets.

REMOTE CONTROL

Input signals:	Output signals:
•	• IR signals to the DVD device

WIRELESS HEADPHONES

Input signals:	Output signals:
Wireless communication (IR): • DVD device (both right and left)	**Wireless communication (IR):** •

REMOTE DIGITAL AUDIO RECEIVER (RDAR) (2007-2012)

DESIGN

CONTROL MODULE

Fig. 11: Locating Remote Digital Audio Receiver
Courtesy of VOLVO CARS CORPORATION

The system for digital radio reception consists of:

- antenna for digital satellite and terrestrial radio
- Remote Digital Audio Receiver (RDAR)

The remote digital audio receiver (RDAR) has the task of receiving digital satellite and terrestrial radio signals. The remote digital audio receiver (RDAR) uses the signal that is the strongest at that instant.

Frequency range for radio reception:

- satellite transmitter 2320.0 - 2332.5 MHz
- terrestrial 2324.2 - 2328.3 MHz

Remote Digital Audio Receiver (RDAR) has CD quality sound. The quality of the sound is not affected by poor reception, the sound is temporarily switched off instead. If the antenna is concealed by a roof box for example.

A Volvo SIRIUS satellite radio subscription must be activated in order for the satellite radio to function. Activation is carried out by the customer ringing Sirius and giving the serial number of the Remote Digital Audio Receiver (RDAR). The serial number can be obtained in the display for the Infotainment module (ICM).

ANTENNA

Fig. 12: Remote Digital Audio Receiver Antenna
Courtesy of VOLVO CARS CORPORATION

The Remote Digital Audio Receiver (RDAR) has an antenna. The antenna receives digital satellite and terrestrial radio signals. The antenna is directly connected to the Remote Digital Receiver (RDAR). The antenna is installed on the roof.

There are diagnostics for the antenna.

DIAGNOSTIC FUNCTIONS

DIAGNOSTIC SYSTEM,

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault.

If a fault disappears for any reason after the diagnostic trouble code (DTC) has been permanently stored in the control module, information about the fault remains in the control module.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function. Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF INPUT AND OUTPUT SIGNALS

This function can be used to continuously read off the values and status of the control module's input and output signals.

READING OFF THE CONTROL MODULE IDENTIFICATION

The diagnostic tool identifies control modules by reading off a number of codes from the control module

memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N

READING OFF EXTENDED FAULT-TRACING INFORMATION

This function can be used to read parameters, status identifiers and counters stored at the same time as a diagnostic trouble code (DTC). These are called frozen values.

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

DOWNLOADING SOFTWARE

Software can be downloaded to the Remote Digital Audio Receiver (RDAR). When software is ordered, the vehicle' software and hardware is compared to Volvo's central database. If they are compatible, the software is downloaded to the system.

If the comparison between the car and Volvo's central database does not correspond, then the database is updated with the vehicle's configuration. When this is complete the software is downloaded.

After replacing the control module the module's unique ID number must be programmed in the Central electronic module (CEM).

If a problem arises after software download and the control module does not work, try switching the ignition off and on.

Select the MOST network for a total download of software to the vehicle.

ACTIVATING A SIRIUS SATELLITE RADIO SUBSCRIPTION

A Volvo SIRIUS satellite radio subscription must be activated for a satellite radio to function.

Activation is carried out by the customer ringing Sirius and giving the serial number for the Remote Digital Audio Receiver (RDAR). The serial number can be obtained in the display for the infotainment control module (ICM).

FUNCTION

RADIO RECEPTION

Fig. 13: Identifying Remote Digital Audio Components
Courtesy of VOLVO CARS CORPORATION

During radio reception, the digital radio signals are received by the antenna system and transmitted to the remote digital audio receiver (RDAR) (16/145) where they are decoded. The remote digital audio receiver (RDAR) then transmits the signals onwards via the MOST network to the infotainment control module (ICM) (16/94) and the integrated audio module (IAM) (16/1) or the audio module (AUD) (16/105) depending on the vehicle configuration.

Remote Digital Audio Receiver (RDAR) uses the signal, satellite or terrestrial, which is strongest at the time.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 14: Locating Remote Digital Audio Receiver
Courtesy of VOLVO CARS CORPORATION

Remote Digital Audio Receiver (RDAR) has the task of receiving both digital satellite and terrestrial radio signals, process them and transmit them onward on the MOST network.

The remote digital audio receiver (RDAR) is located beneath the rear side window on the right side of the vehicle.

The control module has serial optical communication with other components in the MOST network. This means that all communication with Remote Digital Audio Receiver (RDAR) occurs via the Infotainment control module (ICM) or on the initiative of the Infotainment control module (ICM).

The control module checks the input and output signals through an integrated diagnostic system.

The control module communicates with directly connected components, and via MOST communication.

Any diagnostic trouble codes are stored in the control module memory. The information can be read out via the data link connector in the vehicle.

SIGNALS

The table below summarizes the input signals to and output signals from the Remote Digital Audio Receiver (RDAR). The signal types are divided into directly connected signals and MOST communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: • Antenna (16/153)	**Directly connected:** -
Via MOST communication: • Infotainment control module (ICM) (16/94)	**Via MOST communication:** • Infotainment control module (ICM) (16/94) • Integrated audio module (IAM) (16/1) • Audio module (AUD) (16/105)

Fig. 15: Identifying Volvo Component Designations
Courtesy of VOLVO CARS CORPORATION

ROOF-MOUNTED SYSTEM FOR REAR SEAT ENTERTAINMENT (2005-2010)

DESIGN

MONITOR/DVD-PLAYER

Fig. 16: Identifying Roof-Mounted Monitor/DVD-Player
Courtesy of VOLVO CARS CORPORATION

Monitor/DVD-player is central unit in the system for roof-mounted rear seat entertainment. Monitor and DVD-player are integrated and located in the roof between the front seats.

The unit interprets and performs the commands given by the user with the system's infrared remote control. Via external inputs (AV-panel), other audio and video sources can be connected, e. g., game pads or video cameras.

The monitor is an 8 inch TFT LCD-screen with a size format of 16:9 and with a 120 degree horizontal viewing angle. The monitor is manually adjustable in x-axis and via remote control adjustable in y-axis.

The monitor is adapted to both PAL as well as NTSC.

The DVD-player mechanism has an anti-shock system and it helps to prevent the image or sound skipping when played. The DVD-player has Slot-in disc insertion and region coding programmed into the software. The region code can be changed using a security code.

The DVD-player has memory handling to remember where, e. g., in a film different power cut-offs occurred.

The system has 30-feed, that is, supplied directly from the battery. However, there is a signal that informs when the ignition turns off, and a question appears on the monitor if the system is to be active for another hour. Then the system will be shut off automatically and the ignition must be turned on again to start the system. There is also a voltage monitor that turns off the system when the battery voltage is too low.

The built-in loudspeakers can be turned off/on independent of the headphones.

To be able to select external audio and video sources there is an AUX-connection on the back of the unit. 3xRCA for video (yellow) and audio (red and white). AUX-inputs can be used to input signals from video camera, video game pad, VHS-video, MP3-player, portable DVD- or CD-player.

The following media formats can be played by the DVD player:

- DVD-R/+R
- DVD-RW/+RW
- CD-R/+R
- CD-RW/+RW
- CD-3 (80 mm)

The following information formats can be played:

- DVD - Video, Audio
- Audio CD (CD-DA)
- Super Audio CD (SACD)
- MP3 Audio CD/MP3 ID3 Tags ISO 96660
- VCD (Video CD)
- SVCD (Super VCD)
- DivX/MPEG-4

- Photo-CD Kodak
- Photo-CD (JPEG ISO 9660)
- WMA - Video, Audio

Formats such as THX and DolbyDigital are also supported. Only stereo signals of this audio format are reproduced.

For a simple check that the unit is supplied with voltage and grounded, turn on the ignition. The background lighting for the POWER-button should come on. Activate the system by pressing on the POWER-button. Then monitor will be lowered.

Change of DVD player region code

The region coding means that only discs with the region code matching that of the DVD player can be played.

The regional code in the DVD-player can be changed up to 20 times. After that the set region will be locked and cannot be changed again.

NOTE: Warranty repairs due to locked region on the DVD player will not be approved. Region code changes to the region in which the vehicle will be used is to be done at the workshop. The security code is not to be given to the customer.

Do as follows to open the menu for region code change:

1. Switch on the ignition.
2. Switch on the system

   NOTE: There must not be a disc in the DVD player.

3. Point the remote control at a screen and hold down the button for child lock for approx. 5 seconds. The menu SERVICE MENU will be shown with four starts underneath.
4. Enter the code 1971 using the arrow keys on the remote control and then press OK.
5. Select menu REGION CODE and press OK.
6. Select the region code which applies to the relevant vehicle and press OK.
7. Check that the set region code, which will be shown in the top left-hand corner of the screen corresponds with the region where the vehicle will be used.
8. Switch off the system

The submenu can then be used to select a new region for the DVD player.

HEADPHONES

Fig. 17: Identifying Headphones
Courtesy of VOLVO CARS CORPORATION

The wireless IR-headphones can be used for all passengers in the rear seats. Standard audio is transmitted via IR to the headphones in two-channel stereo format. The headphones are powered by an internal battery. The headphones are turned on with a button on one side and the volume, in each headphone, can be adjusted with a knob.

REMOTE CONTROL

Fig. 18: Identifying Remote Control
Courtesy of VOLVO CARS CORPORATION

The remote control can be used to switch between different audio and/or video inputs in the system:

- DVD player, audio/video
- AUX-panel, audio or audio/video

The remote control can be used to navigate in the menu systems, system menu, DVD-menu and service menu.

DIAGNOSTIC FUNCTIONS

TEST SEQUENCE AFTER INSTALLATION

Handling	Expected result	Remarks
Insert the key and turn on the ignition.	RSE in standby mode, power-button lights up.	The RSE-system has a "last memory handling", that is, if the monitor was down the last time the vehicle was turned off, the monitor will be lowered when the ignition is activated again.
Activate RSE by pressing on the power-button.	The monitor is lowered and remaining buttons on the control panel light up.	
Engage reverse.	The monitor comes up.	The signal comes from the left back-up light.
Disengage reverse.	The monitor goes down.	
Remove the key.	The dialogue box on the monitor shows: "CHOOSE YES TO CONTINUE 1 HOUR"	
Choose "NO".	The RSE-system is inactivated and the monitor is lowered.	
Insert the key again and turn on the ignition.	The RSE-system is activated and the monitor is lowered.	
Turn off the system with the power-button.	The monitor comes up again.	This is only done so that the system shall be in stand-by the next time that the ignition is turned on.
Remove the key.	The RSE-system is inactivated.	

TROUBLESHOOTING INFORMATION

The roof-mounted system for rear seat entertainment (RSE) does not include any diagnostic functions and is not connected to the vehicle's CAN-net.

This means, e. g., that no diagnostic trouble codes can be read out from the unit. All troubleshooting must take place using symptom troubleshooting.

The following is troubleshooting information that may facilitate when troubleshooting in the system.

Symptom	Malfunction cause	Malfunction investigation
The system does not start.	1. No ignition 2. Reverse gear is engaged 3. Poor batteries in remote control 4. Low voltage on the car battery 5. Blown fuse 6. Poor connection	1. Switch on the ignition. 2. Disengage reverse gear 3. Replace batteries in remote control 4. Start car engine 5. Check fuse 6. Check connections

Monitor does not turn off.	1. Poor batteries in remote control 2. Blown fuse	1. Replace batteries in remote control 2. Check fuse
No contact with DVD-player.	1. DVD-player is not selected as media source 2. No or defect disc in DVD-player 3. System is off 4. Blown fuse	1. Select DVD-player as media source 2. Change DVD-disc 3. Switch on the system 4. Check fuse
DVD-player does not eject disc.	1. System is off 2. Blocking 3. No or defect disc in player 4. Blown fuse	1. Switch on the system 2. Remove blocking 3. Wait 20 seconds and try to eject disc again. If nothing happens, try inserting a disc to, see if the DVD-player is empty. 4. Check fuse
System does not react to signals from remote control.	1. No ignition 2. Poor batteries in remote control 3. Blown fuse	1. Switch on the ignition. 2. Replace batteries in remote control 3. Check fuse
No or poor sound in headphones.	1. Poor batteries (only IR-headphones) 2. Headphones not on (only IR-headphones) 3. Headphones not correctly connected (only wired headphones) 4. System is off 5. Volume too low 6. No or defect disc in DVD-player 7. Headphones are outside IR-coverage (only IR-headphones) 8. Incorrect media source selected	1. Change batteries in headphones 2. Turn on headphones 3. Unplug and plug in headphone cable in correct outlet 4. Switch on the system 5. Increase volume 6. Eject disc. If nothing happens, try inserting a disc to, see if the DVD-player is empty. 7. Test headphones closer to IR-transmitter 8. Select correct media source
No or poor picture on monitor.	1. Disc cannot be copied 2. Disc has unknown format 3. System is not on 4. No or defect disc in DVD-player	1. Contact dealer who sold disc 2. Use a disc with correct format 3. Switch on the system 4. Eject disc. If nothing happens, try inserting a disc to, see if

	5. Incorrect media source selected	the DVD-player is empty. 5. Select correct media source
No or poor sound in loudspeakers.	1. Sound is off 2. Volume too low 3. System is not on 4. No or defect disc in DVD-player 5. Incorrect media source selected	1. Turn on sound 2. Increase volume 3. Switch on the system 4. Eject disc. If nothing happens, try inserting a disc to, see if the DVD-player is empty. 5. Select correct media source

FUNCTION

REAR SEAT ENTERTAINMENT SYSTEM

Fig. 19: Identifying Rear Seat Entertainment System Components
Courtesy of VOLVO CARS CORPORATION

The system can either be switched on with the POWER button or with the POWER button on the remote control.

If the system is on when the ignition is turned off, a question appears on the monitor if you want to continue using the system for another hour. Within that time, the ignition has to be turned on again, so that the system is not turned off automatically when time is up.

If the system is to be turned on with the remote control, the ignition must be on and the remote control pointed at the monitor/DVD-player.

System start-up

When the ignition is turned on, lighting is turned on in the POWER-button and the system will go to standby mode. When the POWER-button is pressed in, the system is activated and the monitor closes automatically.

The remote control can be used to turn on/off the system and navigate in the menu system:

- Switch between audio/video source (DVD and AUX).
- Image adjustment (image color, brightness, contrast and aspect ratio).
- Audio settings (bass, treble, volume and balance).
- Language selection for on-screen instructions.

A permanent memory stores the shown instruction language used as well as current settings for audio and video. These settings are loaded at start with exception of the volume which is set to low level as standard.

The system is powered via X-feed and directly from the battery. If the system is operating when the ignition is switched of, a question will appear on the monitor as to whether continued play is permitted.

If the user answers YES, the system will continue playing for another 1 hour. Then the system will be turned off.

If there is no answer to the question, the system will be turned off in 1 minute.

To prevent the battery from being discharged, it is not possible to extend playing time without turning on the ignition again. There is also a voltage monitor that turns off the system if the battery voltage is too low.

When a DVD is inserted in the opening, DVD play-back starts automatically unless the DVD has a disc menu. DVD play-back can be restarted from a resting position, e. g., if the ignition is turned off when a film is playing. In this case, the film continues playing from where it stopped the last time when the ignition is turned on again.

HEADPHONES

Fig. 20: Identifying Headphones
Courtesy of VOLVO CARS CORPORATION

The system includes two pairs of IR headphones as standard. Any number of headphones can be used as long as they are within range of the IR transmitter.

Sound is transferred from the screen to the wireless headphones via an infrared signal. There must be free travel between the transmitter in the bottom edge of the screen and the receivers on the side of the headphones. If the way is blocked, sound will be interrupted.

The headphones are switched on with the switch located on the side. The headphones switch off automatically if no IR signal is received for 3-4 minutes.

NOTE: **Lowering the volume of the screen will increase the signal/noise ratio of the headphones. Optimal headphone output is obtained by setting screen volume to 75%. Headphone volume can then be regulated using the wheel on the headphones themselves.**

SYSTEM OVERVIEW

SYSTEM FOR ROOF-MOUNTED REAR SEAT ENTERTAINMENT

Fig. 21: View of Roof-Mounted Rear Seat Entertainment Components
Courtesy of VOLVO CARS CORPORATION

The system for rear seat entertainment is a mobile entertainment to keep the rear seat passengers occupied and amused with TV-games or movies.

The roof-mounted system consists of a unit with an 8-inch monitor with integrated DVD-player. The unit is mounted in the roof between the front seats. The unit has automatic opening/closing of the monitor when it is turned on/off.

The following media formats can be played by the DVD player:

- DVD-R/+R
- DVD-RW/+RW
- CD-R/+R
- CD-RW/+RW
- CD-3 (80 mm)

The following information formats can be played:

- DVD - Video, Audio
- Audio CD (CD-DA)

- Super Audio CD (SACD)
- MP3 Audio CD/MP3 ID3 Tags ISO 96660
- VCD (Video CD)
- SVCD (Super VCD)
- DivX/MPEG-4
- Photo-CD Kodak
- Photo-CD (JPEG ISO 9660)
- WMA - Video, Audio

Formats such as THX and DolbyDigital are also supported. Only stereo signals of this audio format are reproduced.

An AUX-panel with RCA-inputs is found on the back of the DVD-player. Through this, other audio and video sources can be connected to the system, such as video cameras, game pads or portable MP3-, DVD- and CD-players.

The system includes two pairs of wireless headphones. Audio is transmitted to the headphones via an IR-transmitter from the monitor/DVD-player. Wired headphones can also be connected. Audio can also be played via internal speakers in the unit.

Control of the system is also possible with an infrared remote control.

SIGNALS

The tables below include the input and output signals for the unit in the system for rear seat entertainment.

MONITOR/DVD-PLAYER

SOFTWARE DOWNLOADING (2003-2012)

DOWNLOADING SOFTWARE

When software is to be downloaded to the vehicle there are a number of stages in the downloading procedure in VIDA:

- Preparations
- Verification
- Downloading
- Diagnostic services
- Confirmation
- Completion

PREPARATIONS

The preparations involve, among others that the user shall ascertain that the communications tool is connected and that there is sufficient power supply to the vehicle. VIDA performs a check of the voltage level status and the ignition position.

VERIFICATION

During verification, VIDA compares the software, hardware and serial number in the vehicle with that supplied in the software package.

If verification is OK, VIDA continues with the download.

If verification is not OK, a mismatch adaptation will be made and the Volvo central database will be updated before downloading can be performed.

DOWNLOADING

All control modules are set to programming mode when software is to be downloaded to a control module. Any existing software in the control module is erased so this cannot affect the new software.

When erasure is complete the new software is downloaded. Once the download has been sent a reset command is sent to the vehicle.

DIAGNOSTIC SERVICES

After the software has been downloaded, diagnostic services are run if necessary, for example, programming of codes or initialisation of windows.

CONFIRMATION

Confirmation involves a confirmation file containing the vehicle's new configuration being created and sent to the Volvo central database. This is to update the Volvo central database with the vehicle's latest status and so a mismatch adaptation is not performed with the next download.

COMPLETION

The software download is completed by erasing all diagnostic trouble codes (DTC) stored in the vehicle.

NOTE: The clock in the vehicle may stop while downloading some software. Check the clock in the vehicle after downloading and adjust if necessary.

OVERVIEW

The vehicle's electrical system consist of a number of control modules on the CAN and MOST network. The functions of the vehicle can be divided between the different control modules in the vehicle. The vehicle's different functions are implemented via the CAN and MOST network. Each control module is loaded with software that executes functions and monitors the control module through integrated diagnostics.

Incorrect or failed functions in the vehicle usually depend on hardware faults, for example, contact play, oxidation, breakages or short-circuiting.

Software is not worn out and its function is not impaired overtime, however, unforeseeable behaviour can occur in software which means it needs to be upgraded. It may also be necessary to upgrade software on account of legislation or when moving to another market.

When starting the control module the primary bootloader starts (PBL) for 20 ms (0.02 seconds). Should the control module receive a programming command (prog) during these 20 ms the control module enters programming mode.

The programming command is sent for approximately 2 seconds so that all control modules have time to execute the command and enter programming mode. If no programming command is sent the control module's application software takes over the function of the control module.

If a reset command is sent to the control modules in programming mode, the control modules will enter normal operating mode.

The primary bootloader means it is always possible for a control module to enter programming mode even if the application software has been corrupted, for example, during unsuccessful downloading.

ORDERING SOFTWARE PRODUCTS

Generally you can divide software downloading into two stages.

First a software product must be ordered and sent from the Volvo central database to the VIDA station. The software must then be downloaded from the VIDA station to the vehicle.

This section describes ordering of a software product.

Each Volvo spare part has a part number, this also applies to software products. A software product is listed in the spare parts catalogue in exactly the same way as any other part.

Ordering a software product is done as follows:

The mechanic specifies which software product is to be ordered and to which vehicle (model and chassis number). This is either done from the spare parts catalogue (via the part number) or via the software tab in VIDA (via software product). Several software products can be ordered at the same time for the same vehicle.

When ordering upgrades no reading is done from the vehicle. VIDA presupposes that the vehicle and the Volvo central database correspond and the software package is supplied to the VIDA station. A verification to ensure that the vehicle and the Volvo central database correspond will be performed before downloading starts.

When ordering re-downloading, VIDA reads the hardware and serial number from the vehicle and update the Volvo central database with information. The software packages is then supplied to the VIDA station.

The system structure for software controls the content of the software package for the ordered software product. A check is made that the software is applicable for the vehicle in question. If the check is not approved, an error message is shown to the mechanic. The mechanic must assess what the error is and reorder the software once the error has been rectified.

When the software package has been supplied to the VIDA station downloading can begin.

RESETTING CUSTOMER PARAMETERS

Before software downloading, VIDA reads in all customer parameters from the vehicle and saves these locally on the VIDA station.

When downloading is complete VIDA restores the customer parameters in the vehicle.

Under the SOFTWARE tab in VIDA there is a RESET CUSTOMER PARAMETERS button, which is used to, see which parameters have been reset in the vehicle. Only parameters whose values have been changed from the factory settings are shown.

SOFTWARE PRODUCTS

The following types of software products are available:

- Re-downloading
- Upgrading
- Total upgrading CAN/MOST
- Add or remove functionality or accessories
- Individual configuration

RE-DOWNLOADING

The software product re-downloading is used when a control module has been replaced. In order to obtain software that corresponds with the replaced control module the vehicle data is read when placing the order.

Diagnostic services are run after downloading when necessary (e. g. programming of code).

UPGRADING

Software product upgrading is used to upgrade the software in the control module when there has been a complaint and there is a solution available to correct the issue.

VIDA does not read the vehicle data on ordering as no hardware is to be replaced during an upgrade.

If the latest software is already installed in the control module, the software package is not put together, the user receives the message that the control module already contains the latest software.

TOTAL UPGRADING CAN/MOST

The software product total upgrade is used to upgrade the software in several control modules on the CAN or MOST network.

Total upgrade involves building a software package for the control modules needing upgraded software. It all the control modules already have the latest software, no software package is formed.

ADD OR REMOVE FUNCTIONALITY OR ACCESSORIES

The software product adds/removes the functionality used to increase or decrease the functionality in the vehicle. This is primarily done through modifying the vehicle configuration file in the Central electronic module (CEM) (applies to accessories that do not require hardware replacement).

Modified functionality in the vehicle is achieved by changing this file. In addition there are some functions that require software to be downloaded, for example, when you add a control module to the vehicle.

The software product remove functionality does not erase any software, it changes a parameter in the vehicle configuration file so that the control modules in the vehicle interpret this as if the function no longer exists.

INDIVIDUAL CONFIGURATION

The software product individual configuration is used to replace the software in a control module, so it no longer corresponds with the System structure for software. The system product individual configuration is not included in the spare part catalogue in VIDA (Volvo scan tool).

If an individual configuration has previously been downloaded to the vehicle the mechanic receives a warning before this is replaced.

A list of software products for individual configuration is available in the Technical Journals.

THE VOLVO CENTRAL DATABASE

The Volvo central database contains information about all Volvo cars in the world from model year 1999.

This includes information about the vehicles configuration, i. e. how the car is equipped, where the car was built, the vehicle structure week and VIN number.

It also contains information about which control modules are installed in the vehicle as well as their hardware, software and serial number. For S40 (-04) and V40 there is only a limited amount of information in the Volvo central database.

In the system structure for software, there are links between control modules and compatible software. The system structure of the software ensures that it is always the latest release of compatible software, which is included in the software package when ordering software re-downloading or upgrades.

STARTER MOTOR (2003-2012)

DESIGN

EXPLODED VIEW OF THE STARTER MOTOR

Fig. 22: Cut Away View Of Starter Motor
Courtesy of VOLVO CARS CORPORATION

The starter motor consists of:

1. Drive cover
2. Gear wheel
3. Solenoid magnet

4. Battery terminal
5. Rear end and bearing
6. Carbon brush holder and carbon brushes
7. Commutator
8. Armature
9. Permanent magnet
10. Armature housing
11. Planetary train
12. Lever with free rotating clutch
13. Engagement unit for the pinion.

NOTE: **The starter motor of the V8 engine is equipped with field windings instead of permanent magnets. The field windings are electrically connected in series with the carbon brushes.**

Fig. 23: Identifying Starter Motor Terminals
Courtesy of VOLVO CARS CORPORATION

Starter motor terminals:

- #1 (30) From the battery positive terminal

- #2 (50) From starter motor relay.

Ground terminal via gearbox / cylinder block.

PRINCIPLE

Fig. 24: Identifying Starter Motor Operation Principle
Courtesy of VOLVO CARS CORPORATION

The starter motor is a DC motor which uses a permanent magnet. This type of motor operates following the principle that the same poles (North/North) are forced away from each other and opposite poles (North/South) are drawn to each other.

CONTROL SOLENOID

Fig. 25: Control Solenoid

Courtesy of VOLVO CARS CORPORATION

The control solenoid has two functions. The first is to mechanically engage the pinion in the flange/flywheel gear collar. The other is to function as a relay and to handle the greater current required to drive the starter motor when the pinion engages with the gear collar.

The control solenoid consists of the following components:

1. Moving steel cores. Moved by pull-in winding in the control solenoid, slides the pinion into position and moves the moving switch towards the fixed switches
2. Pull-in winding. Pull in the moving steel core. Disconnect when the moving steel core reaches the bottom position
3. Hold-in winding. Holds the moving steel core in position for as long as the control solenoid is supplied
4. Fixed steel cores. Stop position for the moving steel core
5. Contact spring
6. Fixed contacts. Closes when the moving switches reach the fixed switches
7. Terminals. One for the battery and one for the DC motor
8. Moving switch. Switch which closes the fixed switches
9. Moving shaft. Affected by the moving steel core and connects the moving switches with the fixed switches
10. Return spring. Resets the control solenoid components to the rest position when the starter motor relay is disconnected.

FREEWHEEL

Fig. 26: Freewheel
Courtesy of VOLVO CARS CORPORATION

Functions as a one way clutch (freewheel). The freewheel allows the starter motor to drive the car engine, but not the other way around. This prevents the starter motor from being over-revved. This is carried out by spring-loaded rollers which lock the pinion and gear together when the starter motor operates.

The engine cannot drive the starter motor because the pinion turns in the rollers.

The freewheel clutch is attached to the armature shaft by spiral splines, which facilitate engagement and

disengagement of the starter motor pinion / flywheel ring gear.

The left-hand illustration displays the normal position. The starter motor, connected to the outer section drives the pinion (inner section) by means of the rollers, which then lock.

The right-hand illustration displays what happens when the starter motor remains connected when the engine is started. The pinion (inner section) cannot drive the starter motor (outer section) because the rollers disengage.

PLANETARY TRAIN

Fig. 27: Identifying Planetary Train
Courtesy of VOLVO CARS CORPORATION

The planetary train is used to reduce the rotation speed of the pinion gear in relation to the speed of the armature and to increase the torque of the pinion.

The planetary train consists of:

1. Pinion shaft with splines
2. Ring gear (fixed section)
3. Planetary gear (connected to the pinion shaft)
4. Sun gear (connected to the rotor)
5. Armature
6. Commutator

FUNCTION

ENGAGING THE PINION

Fig. 28: Engaging Pinion
Courtesy of VOLVO CARS CORPORATION

When the ignition key is turned to position II, the starter motor relay is supplied power at position 86. If the immobilizer check is OK, the central electronic module (CEM) or engine control module (ECM) supply the relay with a ground connection at position 85 and the relay is activated. Depending on the type of engine management system, the starter motor relay is regulated by either the central electronic module (CEM) or the engine control module (ECM).

Solenoid position #2 (50) is supplied power from relay position 87. This creates a magnetic field in both the pull-in and hold-in winding. This generates a movement of the moving steel core. When the core moves, a lever fixed to the end of the core causes the starter motor 's pinion to mesh with the crown wheel on the flywheel/carrier.

The pull-in winding is grounded through the rotor and carbon brushes. This ground connection is lost when the moving switches close the circuit and the current passes from the solenoid to the starter motor.

PLANETARY TRAIN

Fig. 29: Identifying Planetary Train
Courtesy of VOLVO CARS CORPORATION

When the starter motor rotates, the sun wheel rotates clockwise. The planetary gears, which are constantly engaged with the sun wheel and ring wheel, rotate counter-clockwise. As the ring wheel is secured, the planetary gears are forced to circle around the sun wheel clockwise. The planetary gears rotate more slowly than the sun wheel. It is the clockwise rotation of the planetary gears which drives the pinion. The speed reduction that occurs between the sun gear and the planetary gear, results in greater torque. This means that a smaller and lighter starter motor can be used.

STARTING THE ENGINE

Fig. 30: Identifying Engine Start
Courtesy of VOLVO CARS CORPORATION

When the moving steel cores for the solenoids reach their limit position the moving switches break the circuit with the fixes switches and the pull-in winding is disconnected. The hold-in winding keeps the switches closed. The current now passes through the positive carbon brushes and the armature winding. Grounding is carried out through the negative carbon brushes. This current creates a magnetic field in the rotor, which starts the rotor rotating. When the rotor rotates, the magnetic field is generated continuously depending on how the commutator and the windings are organized on the rotor. This allows the rotor to continue rotating.

NOTE: The starter motor of the V8 engine is equipped with field windings instead of permanent magnets. The field windings are electrically connected in series with the carbon brushes.

When the ignition key is released the starter motor relay is deactivated and the circuit for the hold in winding is broken. Then the return spring for the solenoid pulls the pinion back, at the same time as the fixed and moving switches separate and the current to the starter motor is broken.

SYSTEM OVERVIEW

OVERVIEW

Fig. 31: Identifying Starter Motor
Courtesy of VOLVO CARS CORPORATION

This document describes the principle design and function of a starter motor, regardless of the make.

The starter motor (6/25) cranks the engine to make starting possible. The starter motor is located on the transmission side of the engine block. The exact location depends on engine type. A solenoid causes a pinion to mesh with the crown wheel on the engine's flywheel/carrier. When the engine has started and engine speed exceeds starter motor speed, the pinion disengages. This prevents overcranking of the starter motor.

This type of starter motor is equipped with permanent magnets instead of field windings (except for the V8 engine, which has field windings).

The starter motor gives the greatest torque at low rpm at the same time as the voltage current through the starter motor is greatest.

NOTE: The engagement time for the starter motor must not exceed 20-30 seconds. Longer engagement time results in the starter motor overheating and becoming damaged.

The starter motor solenoid is controlled by a starter motor relay (2/35). The relay, in turn, is controlled by the ignition switch (3/1) together with either the central electronic module (CEM) (4/56) or the engine control module (ECM). The engine management system of the vehicle determines whether the starter motor relay is regulated by the central electronic module (CEM) or the engine control module (ECM).

STEERING WHEEL ANGLE SENSOR MODULE (SAS) (2005-2012)

DESIGN

STEERING WHEEL ANGLE SENSOR MODULE (SAS)

Fig. 32: Identifying Steering Wheel Module
Courtesy of VOLVO CARS CORPORATION

After initiation, with the ignition key in position II and when the steering wheel is turned 4.5 degrees in any direction, the steering wheel angle sensor module (SAS) continuously transmits information about the steering wheel angle position to the brake control module (BCM) to calculate the intended direction of travel. The steering wheel angle sensor module (SAS) also transmits information to the suspension module (SUM).

Communication between the steering wheel angle sensor module (SAS) and the brake control module (BCM) occurs on the high speed side of the controller area network (CAN). The steering wheel angle sensor module (SAS) is integrated in the steering wheel module (SWM).

The steering wheel angle sensor module (SAS) is powered via the steering wheel module (SWM).

STEERING WHEEL ANGLE SENSOR

Fig. 33: Identifying Steering Wheel Angle Sensor
Courtesy of VOLVO CARS CORPORATION

The steering wheel angle sensor is incorporated with the SRS contact reel, which in turn is installed on the steering wheel module (SWM). A code wheel is mounted inside the steering wheel angle sensor which follows the movements of the steering wheel. 9 optical digital sensors and 2 analog photo diodes read off the code wheel. The signal must create a specific pattern. This information is transmitted to the steering wheel angle sensor module (SAS) which uses these signals to calculate the steering wheel angle, speed and number of turns. In total, the steering wheel angle sensor can measure a range of +/- 720 degrees, although the steering wheel can only be turned a maximum of +/-540 degrees.

Due to the reliance of the DSTC (Dynamic stability and traction control) system on information from the steering angle sensor it is extremely important that the contact reel has been centered correctly and that only an original Volvo steering wheel is used.

DIAGNOSTIC FUNCTIONS

OVERVIEW

Fig. 34: Identifying Steering Wheel Module
Courtesy of VOLVO CARS CORPORATION

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. If a fault disappears for any reason after the diagnostic trouble code (DTC) has been permanently stored in the control module, information about the fault remains stored in the control module.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Diagnostic trouble codes (DTCs) stored in the control module can be read off using this function.

Diagnostic trouble codes (DTCs) must be read off at least once before they can be erased.

READING OFF INPUT AND OUTPUT SIGNALS

This function can be used to continuously read off the status of the control module's input and output signals.

For further information about parameters, see: **DESCRIPTION OF PARAMETERS**

READING OFF THE CONTROL MODULE IDENTITY

VIDA identifies the control modules by reading off a number of codes from the control module memory.

The codes contain the following information about the control module:

- hardware P/N
- software P/N
- diagnostic software P/N.

FUNCTION

See the section about the Active Yaw Control (AYC) in **BRAKE CONTROL SYSTEM - DESIGN AND FUNCTION**

SOFTWARE DOWNLOADING

New software can be downloaded into the steering wheel angle sensor module (SAS). When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module. If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 35: Identifying Steering Wheel Angle Sensor Module (SAS) & Steering Wheel Module (SWM)
Courtesy of VOLVO CARS CORPORATION

1. The steering wheel angle sensor module (SAS) is integrated in the steering wheel module (SWM)
2. Steering wheel angle sensor.

Only cars equipped with DSTC (dynamic stability and traction control) have a steering wheel angle sensor module (SAS). The easiest way to determine if a car is equipped with DSTC (Dynamic stability and traction control) is to search for a switch, marked DSTC, positioned in the panel on the climate control module (CCM).

The steering wheel angle sensor module (SAS) is integrated in the steering wheel module (SWM). The only function of the steering angle sensor module (SAS) is to process the signals from the steering wheel angle sensor. The signals used by the DSTC system. The steering wheel angle sensor is installed on the steering wheel module (SWM). The sensor is directly connected to the steering wheel angle sensor module (SAS). The steering wheel angle sensor module (SAS) transmits signal information, via the high speed side of the controller area network (CAN), to the brake control module (BCM) and suspension module (SUM).

If a fault occurs, the steering wheel angle sensor module (SAS) detects this and a diagnostic trouble code (DTC) is stored. The DSTC function is switched off.

Diagnostic trouble codes (DTCs) stored in the steering wheel angle sensor module (SAS). This information can be read off using VIDA via the data link connector (DLC) in the vehicle.

SIGNALS

The table below summarizes input and output signals to and from the steering wheel angle sensor module (SAS). The signal types are divided into directly connected signals, serial communication and controller area network (CAN) communication.

Input signals	Output signals
Directly connected: • **The steering wheel angle sensor** (7/91). Provides the steering wheel angle sensor module (SAS) with relevant information about the steering wheel angle from the	**Directly connected:** -

straight ahead position, the speed of the steering wheel movements and about which direction the steering wheel is turned.	
Via Controller Area Network (CAN) communication: -	**Via Controller Area Network (CAN) communication:** • **Brake control module (BCM)** (4/16). The steering wheel angle sensor module (SAS) provides the brake control module (BCM) with information about the steering wheel angle from the straight ahead position, the speed of the steering wheel movements and about which direction the steering wheel is turned • **Suspension module (SUM)** (4/84). The steering wheel angle sensor module (SAS) provides the suspension module (SUM) with information about the position of the steering wheel and the speed at which it is turned.

STEERING WHEEL MODULE (SWM) (2003-2004)

DESIGN

STEERING WHEEL BUTTONS

Fig. 36: Identifying Steering Wheel Control Buttons
Courtesy of VOLVO CARS CORPORATION

The steering wheel buttons control functions and menu selection for:

- Traffic information (option)
- Audio (option)
- Carphone (option)
- Cruise control (option).

The signals from the steering wheel buttons are transmitted via serial communication.

The steering wheel buttons are connected in series to the steering wheel module (SWM) via contact reel in the steering wheel hub. The steering wheel buttons are connected in the following order, counted from the contact reel:

1. Cruise control
2. Audio /carphone
3. Traffic information.

There are diagnostics for the steering wheel buttons.

DIAGNOSTIC FUNCTIONS

OVERVIEW

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. 35 diagnostic trouble codes (DTCs) can be stored. A fault which is detected in the most recent operating cycle is defined as permanent. Other faults which are detected are defined as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF INPUT AND OUTPUT SIGNALS

This function can be used to continuously read off the status of the control module's input and output signals.

For further information about parameters, see **DESCRIPTION OF PARAMETERS** .

READING OFF EXTENDED DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION

This function can be used to read parameters, status identifiers and counters stored at the same time as a diagnostic trouble code (DTC). These are called frozen values.

For further information, see **FROZEN VALUES STEERING WHEEL MODULE, DESCRIPTION**.

READING THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain the following information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N.

DESCRIPTION OF PARAMETERS

NOTE: The parameters that can be read off for the steering wheel module display how the steering wheel module interprets the position on the buttons and control stalks. In the event of a fault in the buttons or the wiring, the status will be constantly On or Off depending on the position on the buttons and control stalks.

HIGH BEAM FLASH, STATUS

The value is displayed if the high beam flash is activated.

Not activated

Flash

Rocker position high beam / low beam

READ BUTTON, STATUS

The value indicates if the read button is pressed in.

Not activated

Activated

RESET BUTTON, STATUS

The value indicates if the reset button is pressed in.

Not activated

Activated

RIGHT-HAND INDICATOR LAMPS, STATUS

This value indicates whether the right-hand indicator lamps are activated.

Not activated

Activated

LEFT-HAND INDICATOR LAMPS, STATUS

This value indicates whether the left-hand indicator lamps are activated.

Not activated

Activated

CRUISE CONTROL ON / OFF BUTTON, STATUS

This value indicates whether the cruise control on / off button is pressed in.

Not activated

Activated

CRUISE CONTROL +BUTTON, STATUS

This value indicates whether the +button is pressed in.

Not activated

Activated

CRUISE CONTROL -BUTTON, STATUS

The value indicates whether the -button is pressed in.

Not activated

Activated

CRUISE CONTROL RESUME BUTTON, STATUS

This value indicates whether the cruise control resume button is pressed in.

Not activated

Activated

CRUISE CONTROL DISENGAGE BUTTON, STATUS

This value indicates whether the cruise control disengage button is pressed in.

Not activated

Activated

AUDIO / CARPHONE SEARCH+ BUTTON, STATUS

This value indicates whether the audio / carphone search+ button is pressed in.

Not activated

Activated

AUDIO / CARPHONE SEARCH- BUTTON, STATUS

This value indicates whether the audio / carphone search- button is pressed in.

Not activated

Activated

AUDIO / CARPHONE VOLUME+ BUTTON, STATUS

The value indicates whether the audio / carphone volume+ button is pressed in.

Not activated

Activated

AUDIO /CARPHONE VOLUME- BUTTON, STATUS

This value indicates whether the audio / carphone volume- button is pressed in.

Not activated

Activated

CARPHONE YES BUTTON, STATUS

This value indicates whether the carphone YES button is pressed in.

Not activated

Activated

CARPHONE NO BUTTON, STATUS

This value indicates whether the carphone NO button is pressed in.

Not activated

Activated

ROAD TRAFFIC INFORMATION (RTI) RIGHT-HAND BUTTON, STATUS

This value indicates whether the road traffic information (RTI) right-hand button is pressed in.

Not activated

Activated

ROAD TRAFFIC INFORMATION (RTI) LEFT-HAND BUTTON, STATUS

This value indicates whether the road traffic information (RTI) left-hand button is pressed in.

Not activated

Activated

ROAD TRAFFIC INFORMATION (RTI) UP BUTTON, STATUS

This value indicates whether the road traffic information (RTI) up button is depressed.

Not activated

Activated

ROAD TRAFFIC INFORMATION (RTI) DOWN BUTTON, STATUS

This value indicates whether the RTI down button is pressed in.

Not activated

Activated

ROAD TRAFFIC INFORMATION (RTI) ENTER BUTTON, STATUS

This value indicates whether the road traffic information (RTI) enter button is pressed in.

Not activated

Activated

ROAD TRAFFIC INFORMATION (RTI) RESET BUTTON, STATUS

This value indicates whether the road traffic information (RTI) reset button is depressed.

Not activated

Activated

WINDSCREEN WASHER, STATUS

This value indicates whether the windscreen wiper lever is activated in the washer position.

Not activated

Activated

HIGH SPEED POSITION, STATUS

This value indicates whether the windscreen wiper lever is activated in the high speed position.

Not activated

Activated

LOW SPEED POSITION, STATUS

This value indicates whether the windscreen wiper lever is activated in the low speed position.

Not activated

Activated

INTERMITTENT POSITION, STATUS

This value indicates whether the windscreen wiper lever is activated in the intermittent position.

Not activated

Activated

SINGLE SWEEP POSITION, STATUS

This value indicates whether the windscreen wiper lever is activated in the single sweep position.

Not activated

Activated

FROZEN VALUES STEERING WHEEL MODULE, DESCRIPTION

EXPLANATION

Not all the parameters described need to be implemented in the control module. This varies from system to system.

Frozen values are parameter values that are stored when a diagnostic trouble code (DTC) is stored.

BATTERY VOLTAGE, VALUE

Measurement range: 0-28.4 V

Normal value when the generator (GEN) is charging: 13.0-14.5 V

The value indicates the voltage at the steering wheel module.

DISTANCE, VALUE

Measurement range: 0-1048575 km

The value indicates the total mileage of the car at the time the diagnostic trouble code (DTC) was stored.

PASSENGER COMPARTMENT TEMPERATURE, VALUE

Measurement range: -60 to +195 °C

The value indicates the passenger compartment temperature at the time the diagnostic trouble code (DTC) was stored.

OUTSIDE TEMPERATURE, VALUE

Measurement range: -128 to +127.75 °C

The value indicates the outside temperature at the time the diagnostic trouble code (DTC) was stored.

ENGINE RUNNING, STATUS

The status displays whether the engine was running when the diagnostic trouble code (DTC) was stored.

Yes = the engine was running

No = the engine was not running

TIME, VALUE

The value displays the time that has passed since the diagnostic trouble code (DTC) was stored.

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the steering wheel module (SWM). When ordering software, the hardware and the software in the car is compared to the data in the Volvo central database. If the comparison is

OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

The control module is integrated in the steering wheel bracket. The steering wheel must be removed to replace the control module.

FUNCTION

TRIP COMPUTER AND DISPLAYING/ERASING TEXT MESSAGES

Fig. 37: Driver Information Module And Steering Wheel Module Input/Output Signals
Courtesy of VOLVO CARS CORPORATION

The left-hand control stalk is used to control the trip computer and to display and erase text messages in the driver information module (DIM) (5/1). The steering wheel module (SWM) (3/130) transmits information to the driver information module (DIM) on the Control area network (CAN) indicating which function is selected.

The trip computer menu is controlled using the ring on the left-hand control stalk. Turn the ring forwards or backwards to scroll through the menu one step at a time. Some menu selections, such as average speed and fuel consumption, can be reset using the RESET button.

Error messages displayed in the driver information module display are erased using the READ button.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 38: Identifying Steering Wheel Module
Courtesy of VOLVO CARS CORPORATION

The steering wheel module (SWM) has the task of managing the signals for those functions which can be controlled via the steering wheel control stalks and buttons. The signals are transmitted to the relevant control modules via the control area network (CAN). The actual functions are not in the steering wheel module (SWM).

The steering wheel module (SWM) manages the control signals for the following functions:

- Volume control and CD track / radio selection
- Volume control during hands free carphone calls and menu selection for the phone module (PHM)
- Menu selection for traffic information
- Front windshield wipers/washers
- Rear windshield wiper/washer (V70, V70XC/XC70 and XC90)
- Cruise control
- Turn signal lamps
- High and low beam
- Trip computer and displaying / erasing text messages in the driver information module (DIM).

The control module is integrated in the steering wheel bracket. The steering wheel must be removed to replace the control module. Control stalks, key pads and switches can be replaced as separate units.

Cars with DSTC also have a steering wheel angle sensor installed in the contact reel in the steering wheel module (SWM).

The steering wheel module (SWM) communicates with directly connected components and communicates with other control modules via the Control Area Network (CAN).

The control module checks activations and input and output signals via an integrated diagnostic system. A diagnostic trouble code (DTC) is stored if the control module detects an error. In certain cases the control module replaces the faulty signal with a substitute signal.

Any diagnostic trouble codes (DTCs) are stored in the control module memory. This information can be read off using VIDA via the data link connector (DLC) in the car.

A simple way to ensure that the steering wheel module (SWM) is powered and grounded is to flash the headlamp high beam or to change the audio or carphone volume.

SIGNALS

The table below summarizes the input signals to and output signals from the steering wheel module (SWM). The signal types are divided into directly connected signals, serial communication and Controller area network (CAN) communication. The following illustration displays the same information with the Volvo component designations.

Input signals	Output signals
Via serial communication: Steering wheel buttons, digital signal from the buttons to the steering wheel module (SWM): • Cruise control control unit (3/4) • Audio/carphone switch (3/131) • RTI switch (3/135).	**Via serial communication:**
Via Controller Area Network (CAN) communication: • Central electronic module (CEM) (4/56).	**Via Controller Area Network (CAN) communication:** • Engine control module (ECM) (4/46) • Transmission control module (TCM) (4/28) • Upper electronic module (UEM) (4/70) • Accessory electronic module (AEM) (4/78) (optional equipment) • Audio module (AUM) 16/1 (optional equipment, not XC90) • Central electronic module (CEM) (4/56) • Driver information module (DIM) (5/1) • Phone module (PHM) (16/60) (optional equipment)

	• Rear electronic module (REM) (4/58) • Road traffic information module (RTI) (16/45) (optional equipment, not XC90) • Infotainment Control Module (ICM) (16/1) (XC90 only).

Fig. 39: Identifying Steering Wheel Module (SWM) Input/Output Signals

Courtesy of VOLVO CARS CORPORATION

SUBWOOFER MODULE (SUB) (2003-2008)

DESIGN

CONTROL MODULE

Fig. 40: Locating Subwoofer Module (SUB)
Courtesy of VOLVO CARS CORPORATION

The subwoofer module (SUB) consists of two components:

- a loudspeaker element
- an amplifier.

The loudspeaker element is an 8 inch bass loudspeaker with two sound axes. The impedance is 4 ohms for each sound axis.

The amplifier has two channels, one for each sound axis. The output from each channel on the amplifier is 70 W at 4 ohms. Power booster amplification is set so that the acoustic output from the subwoofer module (SUB) matches the other loudspeaker channels.

When transferring sound signals to the subwoofer module (SUB), the infotainment control module (ICM) allocates a channel on the MOST network. The audio module (AUD) transmits sound signals to the subwoofer module (SUB) via the MOST network. All filtering and sound treatment of the sound signal takes place in the audio module (AUD). Volume control takes place in the Subwoofer module (SUB).

The volume of the Subwoofer module (SUB) is raised or lowered using the volume knob on the infotainment control module (ICM). The infotainment control module (ICM) transmits a request on the MOST network to the subwoofer module (SUB), which then processes the request and actively raises or lowers the volume.

The limiter function in the subwoofer module (SUB) does not permit an increase in the output level if this leads to a fall in sound quality.

The subwoofer module (SUB) is supplied with power by one of the relays in the rear electronic module (REM).

DIAGNOSTIC FUNCTIONS

OVERVIEW

The control module has a built-in diagnostic system, Volvo Diagnostic, which continuously monitors internal functions as well as input and output signals.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. A fault which is detected in the most recent operating cycle is defined as permanent. Other faults are defined as intermittent.

Should a fault disappear for any reason after being permanently stored in the control module as a diagnostic trouble code (DTC), the information remains stored in the control module.

If a fault is no longer permanent, the diagnostic trouble code (DTC) remains as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

NOTE: Certain functions are unavailable until the diagnostic trouble codes (DTCs) have been erased.

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- diagnostic software P/N.

READING OFF EXTENDED FAULT-TRACING INFORMATION

This function can be used to read parameters, status identifiers and counters stored at the same time as a diagnostic trouble code (DTC). These are called frozen values.

For further information, see **DESCRIPTION OF VEHICLE COMMUNICATION INFORMATION** .

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the subwoofer module (SUB). When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

The control module is located on the left-hand side behind the third row of seats.

After replacing the control module, the unique serial numbers of the control module are checked by the infotainment control module (ICM). The installed control module will not work if the serial number is incorrect.

Try turning the ignition off and on if there are problems after the software is downloaded and the control module is not working.

The MOST network is used for a total software reload.

FUNCTION

For further information about the function of the subwoofer module (SUB), see Design and Function, audio module (AUD) in **MEDIA, COMMUNICATION AND NAVIGATION - DESIGN AND FUNCTION**

SYSTEM OVERVIEW

SUBWOOFER MODULE (SUB)

The primary task of the subwoofer module (SUB) is to manage sound reproduction from the audio module (AUD) to the bass loudspeaker.

The bass loudspeakers and amplifier are integrated into the control module. This means that the whole unit must be replaced when replacing the control module.

The subwoofer module (SUB) only functions if the audio module (AUD) is connected to the MOST network.

The subwoofer module (SUB) checks activations and input and output signals via an integrated diagnostic system. A diagnostic trouble code (DTC) is stored if the control module detects a fault. Any diagnostic trouble codes (DTCs) are stored in the control module memory.

The subwoofer module (SUB) uses the MOST network to communicate with other control modules.

In order to work correctly on the MOST network, the infotainment control module (ICM) checks that the serial number in the subwoofer module (SUB) is correct. The subwoofer module (SUB) will not function if the number is incorrect. Try switching the ignition off and on if there are problems when replacing the control module.

A simple way to check whether the subwoofer module (SUB) is functioning is to switch on the radio and to then change the volume. The volume from the subwoofer module (SUB) should rise and fall with the changes.

NOTE: Ensure that the bass loudspeaker is selected in the infotainment control module (ICM). Turn the SEL button on the infotainment control module (ICM).

The subwoofer module (SUB) is on the left-hand side of the cargo compartment.

SIGNALS

The table below summarizes the input signals to and output signals from the subwoofer module (SUB) on the MOST network. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Via MOST communication: (ring network) • Infotainment Control Module (ICM) (16/1) Master control module • Audio module (AUD) (16/105).	**Via MOST communication:** (ring network) • Infotainment Control Module (ICM) (16/1) Master control module).

Fig. 41: Volvo Component Designations

SUN ROOF (2003-2012)

DESIGN

SUN ROOF ASSEMBLY

Fig. 42: Identifying Sun Roof Assembly
Courtesy of VOLVO CARS CORPORATION

1. Sun roof frame
2. Drain channel
3. Glass panel
4. Sunshade (closed)
5. Sun Roof Module (SRM)
6. Motor
7. Drive cables
8. Mechanism

The drive mechanism consists of the Sun Roof Module (SRM), motor and mechanism with drive cables. The Sun Roof Module (SRM) with motor is connected to the vehicle electrical system.

Sun roof frame

Fig. 43: Identifying Sun Roof Frame
Courtesy of VOLVO CARS CORPORATION

The sun roof frame is designed to hold all components together and to maintain rigidity, which keeps the movements of the mechanism stable. The A-frame struts serve as guide rails (1) for the drive mechanism. The guide rails contain fixed notches (8), which are necessary for the function of the mechanism. The center member (2) is riveted between the guide rails to increase frame strength and is used for mounting the edging. The front member (4) houses mountings (3) for the motor and Sun Roof Module (SRM). There are eight mounting points (6) along the guide rails and front member to mount the sun roof in the body.

The frame also serves to lead rain water to the drain hoses housed in the four corners (5). The drain channel, which is not part of the frame, collects the water and leads it to the guide rail channels in the frame. These channels are connected to the drain hoses (5) in the front edge and the drains with drain hoses (7) in the rear edge. The drain hoses, drains and connections between the front crossmember and the guide rails are sealed to prevent water from leaking into the headlining.

Drain channel

Fig. 44: Drain Channel
Courtesy of VOLVO CARS CORPORATION

The drain channel is designed to lead rain water to the guide rail channels. The drain channel is mounted on the mechanism and moves along with the glass panel when it slides back.

When the sun roof is closed, the drain channel lies under the glass panel seals to catch any water that may leak in. When the sun roof is in the tilted position, the drain rail is positioned farther forward to catch rain water and prevent it from entering the passenger compartment.

Glass panel

Fig. 45: Glass Panel
Courtesy of VOLVO CARS CORPORATION

The glass panel (2) and sunshade are the visible components of the sun roof. The glass provides extra light to the drive and passengers while protecting them from cold air and rain. The panel is made of safety glass to protect the driver and passengers. It is mounted on metal reinforcements (3) and side brackets (4). The glass panel is mounted in the drive mechanism with screws in the side brackets. The reinforcements are secured to the glass with adhesive, which provides extra rigidity against impact and wind load. The glass edge is covered with a rubber seal (1) that keeps out rain water and dust.

Sunshade

Fig. 46: Identifying Sunshade & Fasteners
Courtesy of VOLVO CARS CORPORATION

The sunshade protects the driver and passengers from intense sunlight and also serves as an insulator. The sunshade is usually opened and closed manually. If, however, the glass panel is open to the comfort position or is completely open, the sunshade is opened by the drain channel, which moves the sunshade back to the open position. The spring-loaded carriages (1) sit in the guide rail and allow the sunshade to slide easily.

Drive cables

Fig. 47: Drive Cables
Courtesy of VOLVO CARS CORPORATION

1. Drive cables
2. Drive plate

The two sun roof drive cables constitute the connection between the motor and the drive mechanism. Each cable is of a worm type, which moves forward or back by the motor turning a gear wheel. The rear end of the cable is fixed in the drive plate, which is connected to the drive mechanism. The cable moves in the guide rail and drive

tube.

Drive mechanism

Fig. 48: Drive Mechanism
Courtesy of VOLVO CARS CORPORATION

The drive mechanism is depicted above. The mechanism bears the glass panel and moves it to the various positions. The left and right mechanism each have two mounting points for the glass panel (1). The drive mechanism can move through the guide rail on carriages (2). Because the carriages slide through the rail, it must be well lubricated.

The drain channel is mounted on the support (3) and the drive plate on the carriage (4).

SUN ROOF MODULE (SRM)

Fig. 49: Identifying Sun Roof Module (SRM)
Courtesy of VOLVO CARS CORPORATION

The Sun Roof Module (SRM) regulates the sun roof motor with the help of software. This software regulates pinch protection, calibration and drive mechanism movements.

- Pinch protection is a safety requirement to prevent anyone from getting injured when the sun roof is closed. Maximum closing force up to 50 km/h (30 mph) is 100 Nm. Over 50 km/h (30 mph), the closing

force is adjusted based on vehicle speed to compensate for wind resistance.

- The sun roof is calibrated by opening the glass panel to its end position (completely open), which is then set as its zero position. The Sun Roof Module (SRM) must be calibrated for the panel to be able to find its main positions and for the pinch protection function to be active. The sun roof must be calibrated each time it has been disassembled. Calibration is performed following the information in VIDA under Repairing/Cleaning, checking and adjusting.

The following are the main glass panel positions programmed in the Sun Roof Module (SRM):

Tilted position

Fig. 50: Identifying Sun Roof Tilted Position
Courtesy of VOLVO CARS CORPORATION

Closed

Fig. 51: Identifying Sun Roof Closed
Courtesy of VOLVO CARS CORPORATION

Open

Fig. 52: Identifying Sun Roof Open
Courtesy of VOLVO CARS CORPORATION

Comfort position

Fig. 53: Identifying Sun Roof Comfort Position
Courtesy of VOLVO CARS CORPORATION

The Sun Roof Module (SRM) determines the positions using a slotted gear wheel and two light sensors. These measure the number of gear wheel revolutions, which is proportionate to glass panel displacement.

SUN ROOF MOTOR

Fig. 54: Identifying Sun Roof Motor
Courtesy of VOLVO CARS CORPORATION

The sun roof motor is connected (1) to the Sun Roof Module (SRM), which regulates current to the motor. Nominal system voltage is 12 V. Maximum top load during normal operation is 5 A. The motor drives a gear wheel (2), which engages the drive cables and causes them to rotate. The gear wheel has a maximum torque of 2.0 Nm and the motor has thermal overload protection. The motor is mounted with screws in the three mounting points (3) in the sun roof frame.

CAUTION: In the event of mechanical blockage, which is normally prevented by the Sun Roof Module (SRM), the motor can produce a maximum torque of 6.8 Nm. This can damage drive wheels and cables. If the sun roof has been blocked, all sun roof components must be checked and, if necessary, replaced before recalibration.

FUNCTION

SUN ROOF DRIVE MECHANISM

Fig. 55: Identifying Sun Roof Drive Mechanism
Courtesy of VOLVO CARS CORPORATION

1. Drain channel support

2. Carriage
3. Guide link
4. Main arm
5. Front arm
6. Return rod
7. Mounting rail
8. Connecting rod

The three main positions of the glass panel (tilted, closed and completely open) are depicted below. When completely open, the glass panel lies under the vehicle roof.

Tilted position

Fig. 56: Identifying Sun Roof Tilted Position
Courtesy of VOLVO CARS CORPORATION

Closed

Fig. 57: Identifying Sun Roof Closed
Courtesy of VOLVO CARS CORPORATION

Completely open

Fig. 58: Identifying Sun Roof Open
Courtesy of VOLVO CARS CORPORATION

Comfort position

The fourth position (known as the Comfort position) is regulated by the Sun Roof Module (SRM). This position is 80 mm in front of the completely open position. Wind noise is reduced in this position.

Fig. 59: Identifying Sun Roof Comfort Position
Courtesy of VOLVO CARS CORPORATION

When the mechanism slides from the open to the closed position, the it is locked by the notches in the guide rails. The front part of the mechanism stops moving while the rear part slides the rear of the glass panel to the normal closed or tilted position. These positions are electronically regulated. The mechanical stop in the fully tilted position is only used for calibration. The electronically regulated tilted position is slightly lower. The drain rail is part of the mechanism and moves along with it.

ELECTRICAL FUNCTION

The sun roof receives its main input signal from the sun roof switch. The switch has a two-way function and an automatic function. There are two ways to operate the sun roof. If the switch is held, the glass will move to the desired position. A brief press with the switch rearward opens the sun roof to the comfort position. A brief press with the switch forward closes the sun roof completely. Note that the automatic function can be used to move the glass panel from the tilted position to the comfort position. The automatic function cannot be used to close

the glass panel from the tilted position.

When the sun roof is tilted, only continual operation is possible (except for automatic opening from the tilted to the completely open position).

Sun roof motor

Fig. 60: Identifying Sun Roof Motor
Courtesy of VOLVO CARS CORPORATION

1. Battery voltage
2. Sun roof switch, forward
3. Sun roof switch, tilt
4. C cable
5. Body connection
6. Battery voltage
7. Sun roof switch, automatic function
8. Sun roof switch, rearward
9. Sun roof switch, switch feed
10. Body connection

The sun roof switch is connected to the Sun Roof Module (SRM) and the Sun Roof Module (SRM) is connected to the motor.

Input signals to the Sun Roof Module (SRM) are the vehicle communication cable (C cable (4)), battery voltage and the sun roof switch. Numbers 1 and 10 are for the motor's power supply, which goes through the Sun Roof Module (SRM). Sun roof feed (9) is the switch's signal voltage.

CALIBRATION FUNCTION

During calibration, the software of the Sun Roof Module (SRM) detects the sun roof's zero position. The zero position serves as a reference point for the Sun Roof Module (SRM) when the sun roof is operated. This reference point helps the Sun Roof Module (SRM) determine where the main positions of the glass panel should be.

Once calibration is complete, pinch protection is activated. The Sun Roof Module (SRM) then detects if the closing speed of the glass panel decreases, that is to say if something is in the path of the glass panel. Pinch protection is then triggered.

During calibration, glass panel speed is also detected by two light sensors that measure how many revolutions and at what speed the gear wheels of the sun roof motor rotate. The light sensors (1) are located within the sun roof motor. The sun roof motor can handle a drop in voltage down to 9 Volts during calibration and still maintain precision.

Fig. 61: Identifying Light Sensors
Courtesy of VOLVO CARS CORPORATION

If the sun roof stops in the open position when it should be closed, you can pull on the sun roof while holding the switch depressed.

CAUTION: If for some reason the sun roof is blocked and the switch is held in when the sun roof is tiled/open, the Sun Roof Module (SRM) will calibrate its zero position as the position at which the sun roof is blocked. This means that the main positions of the glass panel will be incorrectly programmed.

This problem is remedied by recalibrating the sun roof. First hold the switch pressed in for 5 seconds when in

the tiled/open position. Then open the sun roof to the end position and recalibrate.

If the sun roof should seize, there will not be a diagnostic trouble code in the control module.

WARNING: If the Sun Roof Module (SRM) is not calibrated, the sun roof safety functions (specifically the pinch protection function) and the programmed main positions will not be operational.

CAUTION: In the event of mechanical blockage, which is normally prevented by the Sun Roof Module (SRM), the motor can produce a maximum torque of 6.8 Nm. This can damage drive wheels and cables. If the sun roof has been blocked, all sun roof components must be checked and, if necessary, replaced before recalibration.

Calibration is carried out following the information in VIDA under Repairing/Cleaning, checking and adjusting.

OVERVIEW

Fig. 62: Identifying Sun Roof
Courtesy of VOLVO CARS CORPORATION

The main task to the sun roof is to allow light and ventilation in the passenger compartment. This, in turn, makes the vehicle feel even more luxurious. The glass panel provides extra light to the driver and passengers,

while vehicle ventilation can be regulated by opening or closing the sun roof. The sun roof has four preprogrammed positions:

- Closed
- Tilted
- Comfort
- Completely open.

Other positions can be set manually as desired.

The glass is tinted to protect the driver and passengers from strong sunlight. This tinting also protects against heat. The sunshade can also be used for these purposes.

SUPPLEMENTAL RESTRAINT SYSTEM CONTROL MODULE (SRS) (2005-2012)

DESIGN

CONTROL MODULE

Fig. 63: Locating Supplemental Restraint System (SRS) Control Module
Courtesy of VOLVO CARS CORPORATION

WARNING: **The battery must be disconnected before any work is carried out on the supplemental restraint system (SRS). Otherwise the airbags could accidentally deploy.**

The primary task of the supplemental restraint system module (SRS) is to minimize injuries to the driver and passengers in different types of accident. To do this, the control module validates incoming pulsed collision signals (acceleration signals generated by a collision) and then determines the required action. The control module uses internal sensors as well as external collision sensors. Using the data collected from the sensors, the system determines which of the following will be activated:

- front airbags

- side impact protection (SIPS) bags
- inflatable curtains
- seat belt tensioners
- adaptive steering column (XC90 USA/CDN only).

The collision sensor in the control module registers the longitudinal mechanical stress that occurs in a frontal collision. A side impact may also be registered in the collision sensor. The longitudinal stresses are measured using two acceleration sensors. On vehicles with front impact sensors, these are used to register stresses in the event of a head-on collision. If the longitudinal stresses exceed a certain level, the stress will be calculated (the collision pulse). The calculation evaluates whether the collision pulse was sufficient to activate the airbags and/or the seat belt tensioners. Airbags and seat belt tensioners can be activated individually.

On the XC90, the control module is also able to register if the vehicle is about to roll over. If the sideways tilt and rotational energy of the car exceed a certain level, the control module begins a calculation to determine whether the roll over protection should be activated. The critical tilt angle is 50-55 degrees. All seat belt tensioners and inflatable curtains are deployed if the roll over protection is activated.

For certain models, depending on the market, the following are also used:

- an occupant weight sensor (OWS) located under the seat cushion on the front passenger seat
- two seat position sensors located on the rail under the driver's seat and front passenger seat.

The driver and passenger airbags and the seat belt tensioners are designed to deploy in the event of a frontal collision as necessary. For the XC90 (USA/CDN only), the adaptive steering column will also be activated if necessary.

No seat belt tensioners or airbags will be activated in the event of a collision from the rear.

Two requirements need to be fulfilled in order for the side impact protection system to be activated:

1. that the collision pulse is sufficiently high that a trigger signal is sent from the side impact sensor to the control module
2. the control module or another collision sensor transmits a confirmation signal which allows the collision protection system to be deployed.

The side impact protection system is deployed when the control module has received both an activation and a confirmation signal.

If the side impact occurred at the front of the vehicle the side airbags and the inflatable curtains are deployed on the side that received the impact. If the side impact is towards the rear of the car, only the inflatable curtains are deployed on that side.

The control module has a collision recording function. This records certain system information in the event of a collision. If necessary, this information can be analyzed and used after a collision. This data is used in ongoing development of collision safety systems.

In the event of a frontal collision, side on collision or rear collision a collision signal is transmitted from the supplemental restraint system module (SRS) to the phone module (PHM) and the central electronic module (CEM) using a directly connected cable. The purpose of this signal is to:

- switch off the fuel pump (FP)
- light the interior lighting
- unlock the doors
- if the vehicle is equipped with Volvo On Call (Plus), send an automatic alarm to CSC (Customer Service Center) when the accident has occurred.

A collision signal is also sent to the phone module (PHM) and the central electronic module (CEM) via the Controller area network (CAN).

The supplemental restraint system module (SRS) decides to deploy the airbags and/or the seat belt tensioners in the event of a frontal collision. This depends on information such as:

- if the driver and front passenger are wearing seat belts or not
- if there is a fault in the seat belt buckles
- if there is a fault in the controller area network (CAN) communication.

As a result of the above conditions, in the event of a low impact collision the seat belt tensioner may deploy on the driver's side whilst the airbag is deployed on the passenger side.

The SRS indicator lamp lights when the ignition is switched on. If no faults are registered by the control module, either internally or from the sensors, wiring or igniters, a signal is transmitted on the controller area network (CAN) to the driver information module (DIM) confirming that the SRS indicator lamp can be switched off. If there is a fault, the supplemental restraint system module (SRS) transmits information to the driver information module (DIM) indicating which lamp should be lit and the text to be displayed in the combined instrument panel.

The driver information module (DIM) continuously transmits information to the supplemental restraint system (SRS) control module via the controller area network (CAN) about the status of the SRS indicator lamp.

If the SRS indicator lamp stops working, the general warning lamp is used instead.

Note that after a collision, it may be necessary to replace the cable harness for the components of the collision protection system which have deployed. This is because the connectors may melt at the moment of deployment. If a connector has melted, the cable harness adjacent to the connector must be replaced.

WARNING: **The battery must be disconnected before any work is carried out on the supplemental restraint system (SRS). Otherwise the airbags could accidentally deploy.**

SIDE IMPACT SENSOR

Fig. 64: Locating Side Impact Sensors
Courtesy of VOLVO CARS CORPORATION

The side impact sensors in the vehicle are used to measure the collision pulses.

The four sensors which are used in the car are:

- 1 side impact sensor in each left and right B post
- 1 side impact sensor in each left and right C post.

The side impact sensors have integrated logic. In the event of a collision, they determine whether the impact was large enough to warrant transmitting an activation signal to the control module to deploy the side impact airbag. Only the side impact protection on the side from which the activation signal was sent can be deployed.

The side impact sensors transmit continuous signals to the control module to indicate that they are working. In the event of a fault in the side impact sensor, a fault signal is transmitted to the control module which then stores a diagnostic trouble code (DTC). A diagnostic trouble code (DTC) is stored when the communication between the control module and one of the side impact sensors does not function. Each side impact sensor has a software ID. The ID is used to check that the correct side impact sensor is installed. This is because the activation level of the signal which is transmitted to the control module is not necessarily the same for the different side impact sensors.

The front (B-post) and rear (C-post) side impact sensors are a different color and have different coding on their connectors to simplify installation.

The front side impact sensors cannot be installed in the position for the rear side impact sensors and vice versa.

Data is transmitted on the same cable used for power supply.

FRONT IMPACT SENSOR (CERTAIN MARKETS AND MODELS ONLY)

Fig. 65: Locating Front Impact Sensors
Courtesy of VOLVO CARS CORPORATION

The frontal impact sensors are used to provide the supplemental restraint system module (SRS) with advance information about the collision pulse. This enables the control module to determine more accurately the components to be activated.

The frontal impact sensors have integrated logic which transmits acceleration data to the supplemental restraint system module (SRS).

The front impact sensors transmit continuous signals to the control module to indicate that they are working. In the event of a fault in a frontal impact sensor, a fault signal is transmitted to the control module which then stores a diagnostic trouble code (DTC). A diagnostic trouble code (DTC) is also stored if the communication between the control module and one of the frontal impact sensors does not function. Each frontal impact sensor has a software ID. The ID is used to check that the correct frontal impact sensor is installed.

Data is transmitted on the same cable used for power supply.

The two frontal impact sensors are inside the left and right-hand headlamps.

SEAT POSITION SENSORS (XC90 USA/CDN ONLY)

Fig. 66: Identifying Seat Position Sensors
Courtesy of VOLVO CARS CORPORATION

The seat position sensor is used to determine the size of the person sitting on the seat. There are two seat position sensors in the car. One is under the driver's seat and the other under the front passenger seat. The seat position sensors are connected directly to the central electronic module (CEM).

The seat position sensor consists of a Hall sensor which alters the current depending on the position of the seat. The seat position sensor has two classifications, these are a small person and a large person.

A small person means that the seat is approximately 10 cm from the first seat position and forwards. Other positions are classified as a large person.

This information is sent onwards on the controller area network (CAN) to the supplemental restraint system (SRS) module. The supplemental restraint system module (SRS) uses this information to optimize the function of the front driver and passenger airbags in the event of a collision.

ADAPTIVE STEERING COLUMN (XC90 USA/CDN ONLY)

Fig. 67: Identifying Adaptive Steering Column
Courtesy of VOLVO CARS CORPORATION

WARNING: **Never use an ohmmeter or similar tool to test airbags, inflatable curtains, the adaptive steering column or seat belt tensioners. Disconnect airbags, inflatable curtains, the adaptive steering column or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.**

When the adaptive steering column in the collision protection system is activated, a pin is deployed which makes the steering column longitudinally adjustable and thus collapsible. If the frontal collision exceeds a certain level the steering wheel is pressed into the dashboard to a greater degree than if the steering column were rigid.

The steering is not affected by the deployment of the pin. The pin is deployed by a pyrotechnical charge and is located in the center of the steering column. The collision protection system in the adaptive steering column only functions if the driver is wearing the seatbelt and if the airbag deploys. The entire steering column must be replaced if the collision protection system in the adaptive steering column has deployed.

OCCUPANT WEIGHT SENSOR (OWS) (CERTAIN MARKETS AND MODELS ONLY)

Fig. 68: Identifying Occupant Weight Sensor (OWS) Components
Courtesy of VOLVO CARS CORPORATION

The occupant weight sensor (OWS) consists of three interactive components:

- The pressure sensor, installed under the front passenger seat
- The seatbelt force sensor, mounted in the seat frame on the outside of the front passenger seat
- Occupant weight sensor module, installed under the front passenger seat.

The pressure sensor and occupant weight sensor are linked via a hose. The pressure sensor registers the pressure the seat is exposed to, for example when someone is sitting in the car. Information from the seat belt force sensor is also used to ensure the good performance of the system. The seatbelt force sensor informs the occupant weight sensor module what force the belt is tensioned with. This is done because the pressure measured by the pressure sensor can be affected by the passenger fastening the seatbelt tightly. This means that the passenger exerts greater pressure on the seat than during normal seatbelt use. The passenger is then interpreted as being heavier than he or she is. The occupant weight sensor module uses the information from both the pressure sensor and seatbelt force sensor to calculate the actual weight of the passenger. The occupant weight sensor (OWS) transmits continuous signals to the supplemental restraint system module (SRS) and occupant weight sensor (OWS) on the LIN bus. If the occupant weight sensor (OWS) does not function correctly the supplemental restraint system module (SRS) will:

- deactivate the front passenger airbag
- light the warning lamp for passenger airbag disconnected (PAD) in the upper electronic module (UEM)
- light the SRS (supplemental restraint system) indicator lamp and display the alert message in the driver information module (DIM).

If a fault occurs in any of the components the following should be noted:

- The pressure sensor and occupant weight sensor module must be replaced at the same time
- The seatbelt force sensor is replaced separately.

NOTE: The on/off switch for the front passenger airbag and occupant weight sensor

(OWS) must not be installed in the vehicle together.

SWITCH ON/OFF, FRONT PASSENGER AIRBAG (NOT USA/CDN)

Fig. 69: Identifying Front Passenger Airbag Switch
Courtesy of VOLVO CARS CORPORATION

This switch is used to activate or deactivate the front passenger airbag. The switch is on the side of the dashboard on the passenger side. The switch can only be accessed with the front passenger door open. The ignition key is used to change the position of the switch. When the switch is in the OFF position, all the stages of the passenger airbag are deactivated and the passenger airbag disconnected (PAD) warning lamp lights. When the switch is moved between OFF and ON, the two Hall sensors detect the position of the switch. The Hall sensors for the switch are directly connected to the supplemental restraint system module (SRS). Each Hall sensor is individually connected to the control module. The signal which is transmitted from the Hall sensors has two different current levels, depending on the position of the switch.

A diagnostic trouble code (DTC) is stored if the signal from the Hall sensors cannot be correctly interpreted. The control module may, depending on the fault, deactivate the passenger airbag. The PAD (passenger airbag disconnected) warning lamp lights if the passenger airbag is deactivated. If a fault is detected and the passenger airbag is not deactivated, the SRS warning lamp lights and a text message is displayed in the driver information module (DIM).

NOTE: The on/off switch for the front passenger airbag and occupant weight sensor (OWS) must not be installed in the vehicle together.

FRONT AIRBAGS

Driver airbag

Fig. 70: Identifying Driver Airbag Types
Courtesy of VOLVO CARS CORPORATION

Front passenger airbag

Fig. 71: Front Passenger Airbag
Courtesy of VOLVO CARS CORPORATION

WARNING: **Never use an ohmmeter or similar tool to test airbags, inflatable curtains, the adaptive steering column or seat belt tensioners. Disconnect airbags, inflatable curtains, the adaptive steering column or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.**

For the XC90 in USA/CDN, the front airbags are:

- driver airbag, 3 stage deployment
- front passenger airbag, 3 stage deployment.

For other models and markets, the front airbags are:

- driver airbag, 2 stage deployment
- front passenger airbag, 2 stage deployment.

The driver's airbag is located in the steering wheel. The passenger airbag is located above the glove compartment in the dashboard.

Each airbag stage has a separate ignition section. These are electrically separated from each other. This means that the different ignition components have their own separate power supply and grounding points from the control module.

When activating the airbags electrical signals are transmitted from the supplemental restraint system module (SRS) to the relevant airbag stage.

Stage 1

Stage 1 of the driver's airbag is pyrotechnic. In the event of activation the charge combusts and the gas which develops is blown into the airbag.

Stage 1 on the passenger airbag consists of a pyrotechnic component in combination with a reservoir which stores a gas. On activation the pyrotechnic charge and mixes with the stored gas. The gas mixture is blown into the airbag.

Stage 2

Stage 2 of the driver's and passenger airbags is pyrotechnical. In the event of activation the charge combusts and the gas which develops is blown into the airbag.

The pace of the airbag 2 stage activation is dependent on collision type and seat belt use. Both stages activate but in the event of a lesser impact, there is a greater time delay between stage 1 and stage 2. For more serious impacts the time delay is shorter between stages 1 and 2.

Stage 3 (XC90 USA/CDN only)

Stage 3 of the driver's and passenger airbags is pyrotechnical. A valve opens on the airbag during deactivation.

The control module uses information from the occupant weight sensor (OWS), seat position sensor and collision sensor to determine the size of the driver/passenger and the force of the collision. The control module adapts the volume of the airbag to the force of the collision. This is done using airbag ventilation.

WARNING: **Never use an ohmmeter or similar tool to test airbags, inflatable curtains, the adaptive steering column or seat belt tensioners. Disconnect airbags, inflatable curtains, the adaptive steering column or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.**

SIDE IMPACT AIR BAGS

Fig. 72: Identifying Side Impact Air Bags
Courtesy of VOLVO CARS CORPORATION

WARNING: **Never use an ohmmeter or similar tool to test airbags, inflatable curtains, the adaptive steering column or seat belt tensioners. Disconnect airbags, inflatable curtains, the adaptive steering column or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.**

There are two side impact protection (SIPS) bags connected to the supplemental restraint system module (SRS). Their connectors are electrically separated from each other. The side impact protection (SIPS) bags are on the outside of the front seats, underneath the upholstery. The side impact protection (SIPS) bags deploy on the side of the impact. Their task is to protect the hips, chest and upper body in the event of a side on collision.

The side airbags together with the inflatable curtains and other safety systems can help to protect the driver and front passenger in the event of a collision.

The side impact protection (SIPS) bag uses a pyrotechnic component in combination with a reservoir which stores a gas. On activation the pyrotechnic charge and mixes with the stored gas. The gas mixture is blown into the airbag.

WARNING: **Never use an ohmmeter or similar tool to test airbags, inflatable curtains, the adaptive steering column or seat belt tensioners. Disconnect airbags, inflatable curtains, the adaptive steering column or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.**

SEAT BELT TENSIONERS

Fig. 73: Locating Seat Belt Tensioners
Courtesy of VOLVO CARS CORPORATION

WARNING: **Never use an ohmmeter or similar tool to test airbags, inflatable curtains, the adaptive steering column or seat belt tensioners. Disconnect airbags, inflatable curtains, the adaptive steering column or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.**

Depending on the model and market, there may be up to seven seat belt tensioners in the vehicle. Two in the front seat, three in the rear seats and two in the third row if applicable. The seat belt tensioners contain an explosive charge which tensions the seat belts when deployed. The seat belt tensioners are separated from each other electrically. This means that each seat belt tensioner has a separate individual power supply and ground from the control module.

The seat belt tensioner tensions the seat belt to reduce the forward movement of the body. This also reduces the forces on the chest from the airbag and seat belt.

The supplemental restraint system module (SRS) determines whether to deploy the seat belt tensioners based on whether the seat belts are being used. The seat belt tensioner will not be activated if the seat belt is not engaged. If the seat belt is fastened and the seatbelt indication does not function for the front seat belt buckles, the seat belt tensioners will be activated anyway.

The seat belt tensioner consists of a pyrotechnical charge and a cylinder with a piston. The piston is connected to a steel cable which is secured to the seat belt reel. When the control module activates the seat belt tensioner the piston is forced downwards by the expanding gas. The piston pulls in the steel cable which reels in the belt.

WARNING: **Never use an ohmmeter or similar tool to test airbags, inflatable curtains, the adaptive steering column or seat belt tensioners. Disconnect airbags, inflatable curtains, the adaptive steering column or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.**

INFLATABLE CURTAINS

XC90

Fig. 74: Identifying Inflatable Curtains
Courtesy of VOLVO CARS CORPORATION

WARNING: **Never use an ohmmeter or similar tool to test airbags, inflatable curtains, the adaptive steering column or seat belt tensioners. Disconnect airbags, inflatable curtains, the adaptive steering column or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.**

Depending on the model and configuration, there are up to four inflatable curtains connected to the supplemental restraint system module (SRS). Their connectors are electrically separated from each other.

For the 7 seater XC90 models, the inflatable curtains are in the roof between the A and D-posts. For the 5 seater XC90 models and other models, the inflatable curtains are in the roof between the A and C-posts.

The configuration is as follows:

- On the 7 seater XC90, side and rear inflatable curtains on each side. There are a total of four inflatable curtains
- On the 5 seater XC90 and other models, there is one inflatable curtain on each side. There are a total of two inflatable curtains.

The inflatable curtains have only one ignition component each. The task of the inflatable curtains is to protect the head and the upper body in the event of a side impact. The supplemental restraint system module (SRS) activates the inflatable curtains on the side where the collision occurred.

The inflatable curtain uses a pyrotechnic component in combination with a reservoir which stores a gas. On activation the pyrotechnic charge and mixes with the stored gas. The gas mixture is blown into the inflatable curtain which falls and covers the side windows and B post. If rear inflatable curtains are installed the C post is also covered.

Where there are two inflatable curtains per side, these are always activated simultaneously.

WARNING: Never use an ohmmeter or similar tool to test airbags, inflatable curtains, the adaptive steering column or seat belt tensioners. Disconnect airbags, inflatable curtains, the adaptive steering column or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.

SRS INDICATION

The supplemental restraint system module (SRS) continuously checks the system. A diagnostic trouble code (DTC) is stored and an SRS indication is made.

SRS indication is accompanied by a text message in the Driver information module (DIM), partly through:

- an SRS warning lamp
- a general warning lamp.

The lamps light depending on how serious the fault is: Information about which lamp should be lit is transmitted by the supplemental restraint system module (SRS) on the controller area network (CAN).

The SRS indicator lamp lights when the ignition is switched on. If no faults are registered by the control module, either internally or from the sensors, wiring or igniters, a signal is transmitted on the controller area network (CAN) to the driver information module (DIM) confirming that the SRS indicator lamp can be switched off. If no faults are detected when the ignition is switched on, the lamp will remain lit for a few seconds. The lamp goes out when the system has been checked and is operating without faults.

The control module has an EEPROM memory which retains data about diagnostic trouble codes (DTCs) even when the battery has been disconnected.

The driver information module (DIM) continuously indicates to the supplemental restraint system module (SRS) the function of the SRS indicator lamp. If the lamp stops working, the general warning lamp lights up and a text message is displayed.

NOTE: If a diagnostic trouble code (DTC) is stored because the resistance in an SRS ignition cable is too high or too low, it is important that the resistance of the SRS ignition cable is not measured when the collision protection system is connected. Special tools with the same resistance as the collision protection system must be used for fault-tracing.

PASSENGER AIRBAG INDICATION

Fig. 75: Identifying Passenger Airbag Indicator Light
Courtesy of VOLVO CARS CORPORATION

Supplemental restraint system module (SRS) transmits signals on the CAN network to the upper electronic module (UEM) if the front passenger airbag is activated or not. If the upper electronic module (UEM) receives information that the passenger airbag is deactivated, the upper electronic module (UEM) lights the passenger airbag warning lamp (PAD). The warning lamp is located in the upper section of the rear view mirror.

Depending on the market, if the switch for activating and deactivating the front passenger airbag is used to deactivate it, the passenger airbag disconnected (PAD) warning lamp lights.

The warning lamp goes out when the airbag is reactivated.

If an occupant weight sensor (OWS) is installed (market and model dependent), the passenger airbag disconnected (PAD) warning lamp lights when the airbag is deactivated. However there is an exception to this:

- The passenger airbag disconnected warning lamp will remain unlit if the occupant weight sensor (OWS) registers that the passenger seat is unoccupied. This means that the passenger airbag is deactivated.

The warning lamp goes out when the airbag is reactivated.

Reasons that the passenger airbag disconnected warning lamp lights may also be:

- communication problems between the supplemental restraint system module (SRS) and upper electronic module (UEM)
- faulty function in the on/off switch for the front passenger airbag
- defective occupant weight sensor (OWS) function.

SEAT BELT BUCKLE

Fig. 76: Locating Seat Belt Buckles
Courtesy of VOLVO CARS CORPORATION

The two front seat belt buckles have Hall sensors and are connected to the SRS module. These connections are electrically separated from each other.

The hall sensor detects whether the belt is engaged in the seat belt buckle or not and indicates this to the supplemental restraint system module (SRS). The information is used to set the activation level for the airbags and seat belt tensioners. If a fault is detected in the seat belt buckles or in their terminals, an adjustment is made for this, depending on the type of fault.

ACTIVATING THE COLLISION PROTECTION SYSTEM

The collision safety system is extremely advanced. It is able to adapt the collision protection system to suit the specific circumstances of a collision. In general it is extremely unlikely that all airbags and seat belt tensioners will be deployed in the same accident. It is possible that only one airbag or seat belt tensioner is deployed. This is determined by the supplemental restraint system module (SRS) based on the forces that occur during the collision.

If the control module deploys the front airbags, all stages will always be activated. By varying the time between the deployment phases, the inflation of the airbag is more gentle for a low speed collision.

ACTIVATION LEVELS FOR THE COLLISION PROTECTION SYSTEM

The table below shows how the SRS system reacts in the event of a frontal impact.

Level 1= Low speed collision

Level 5 = Severe collision

Collision level	Front seat		Rear seat / Rear seat 3rd row
	Seat belt not in use	Seat belt in use	
Level 1	No corrective action.	The seat belt tensioner is activated. The airbags are not	No corrective action.

		deployed.	
Level 2	The airbags are deployed with a slow build-up of pressure. Ventilating the airbags (only XC90 USA/CDN).	The seat belt tensioner is activated. The airbags are not deployed.	No corrective action.
Level 3	The airbags are deployed with a slow build-up of pressure. Ventilating the airbags (only XC90 USA/CDN).	The seat belt tensioner is activated. The airbags are deployed with a slow build-up of pressure. Ventilating the airbags (only XC90 USA/CDN).	The seat belt tensioner is activated.
Level 4	The airbags are deployed with a fast build-up of pressure. Ventilating the airbags (only XC90 USA/CDN).	The seat belt tensioner is activated. The airbags are deployed with a slow build-up of pressure. Ventilating the airbags (only XC90 USA/CDN).	The seat belt tensioner is activated.
Level 5	The airbags are deployed with a fast build-up of pressure. Ventilating the airbags (only XC90 USA/CDN).	The seat belt tensioner is activated. The airbags are deployed with a fast build-up of pressure. The adaptive steering column of the collision protection system is activated (XC90 USA/CDN only). Ventilating the airbags (only XC90 USA/CDN).	The seat belt tensioner is activated.

ACTIVATING THE SIDE IMPACT PROTECTION SYSTEM

The table below shows how the SRS system reacts in the event of a side impact.

	Side impact sensor, left-hand side		Side impact sensor, right-hand side	
	B-post	**C-post**	**B-post**	**C-post**
Left-hand (SIPS) bag	X			
Left-hand inflatable curtain	X	X		
Inflatable curtain left rear (XC90 7 seater only)	X	X		
Right-hand SIPS bag			X	
Right-hand inflatable				

curtain			X	X
Inflatable curtain right rear (XC90 7 seater only)			X	X

DIAGNOSTIC FUNCTIONS

OVERVIEW

Fig. 77: Identifying Supplemental Restraint System (SRS) Diagnostic System
Courtesy of VOLVO CARS CORPORATION

The diagnostic system for the supplemental restraint system (SRS) continually diagnoses the function of supplemental restraint system (SRS) components and stores any diagnostic trouble codes (DTCs). Diagnostic trouble codes can be read via VIDA (Volvo scan tool). Information is presented in VIDA in a manner similar to that of other diagnostic systems.

FAULT INDICATION

If a fault occurs in the SRS system, the driver is warned in various ways via the driver information module (DIM):

- SRS warning lamp and text message in the display
- the general warning lamp and text message in the display.

A VIDA station must be connected to the data link connector (DLC) in order to identify the source of the fault.

DIAGNOSTIC TROUBLE CODES (DTCS)

A diagnostic trouble code (DTC) is stored if the control module detects a fault. The control module can store up to 10 diagnostic trouble codes (DTCs).

Should a fault disappear for any reason after being stored in the control module as a diagnostic trouble code (DTC), the information remains stored in the control module. If a fault is no longer permanent, the diagnostic trouble code (DTC) remains as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

This function can also be used to read off whether the fault is still present (permanent) or whether it has now ceased (intermittent) after the diagnostic trouble code (DTC) has been stored.

Diagnostic trouble codes (DTCs) can only be erased once all the diagnostic trouble codes (DTCs) have been read off at least once.

READING OFF THE PARAMETERS

Data can be read off from the supplemental restraint system module (SRS) using this function.

Vehicle type

Read out which type of vehicle is programmed in the supplemental restraint system module (SRS).

Steering

Read out which type of steering is programmed in the supplemental restraint system module (SRS) - left-hand or right-hand drive.

Passenger airbag

Read out whether the supplemental restraint system module (SRS) is programmed for a front passenger airbag.

Also read out the status of the airbag.

Occupant weight sensor (OWS)

Read out whether the supplemental restraint system module (SRS) is programmed for an occupant weight sensor (OWS).

Switch On/Off, front passenger airbag

Read out whether the supplemental restraint system module (SRS) is programmed for a switch.

Front seat belt buckle

Reads off the status of the driver and passenger seatbelt buckles.

Warning lamp, front passenger airbag (PAD)

Read out whether the supplemental restraint system module (SRS) sends a signal to request illumination of the warning lamp.

READING OFF CONTROL MODULE IDENTIFICATION

VIDA identifies control modules by reading off a number of codes from the control module memory. The codes contain information about the control module:

- hardware P/N (control module without software)
- hardware serial number (control module without software)
- software P/N
- software number, diagnostics
- serial number, side impact sensor.

The following information can also be read off from the control module memory:

- hardware part number for occupant weight sensor (OWS) (certain markets and models only)
- software part number for occupant weight sensor (OWS) (certain markets and models only)

CALIBRATION OF OCCUPANT WEIGHT SENSOR (OWS) (CERTAIN MARKETS AND MODELS ONLY)

The occupant weight sensor (OWS) can be calibrated using this function.

CONFIGURATION OF NUMBER OF SEATS (XC90 ONLY)

This service makes it possible to change the parameter value for number of seats in the supplemental restraint system module (SRS).

ID NUMBER STORAGE FOR OCCUPANT WEIGHT SENSOR (OWS) (CERTAIN MARKETS AND MODELS ONLY)

This service makes it possible to store the ID number of the occupant weight sensor (OWS) in the supplemental restraint system module (SRS).

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software for the supplemental restraint system module (SRS) can be downloaded. When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module.

Software can be downloaded if the comparison between the car and the Volvo central database does not correspond.

When the control module is replaced, the new control module will have certain preprogrammed software.

The software which is preprogrammed is:

- application software
- diagnostic software
- collision algorithm software.

The software which will be downloaded is parameter files containing:

- parameters unique to this model
- vehicle equipment level
- a signal configuration file.

Courtesy of VOLVO CARS CORPORATION

When the ignition key is turned from 0 to I, II or III, the communication on the controller area network (CAN), the status of the internal functions in the supplemental restraint system module (SRS) (4/9) as well as all directly connected components are checked:

- driver's airbag stages 1 and 2 (8/30 and 8/61)
- driver's airbag stage 3 (8/123) (XC90 USA/CDN only)
- passenger airbag stages 1 and 2 (8/31 and 8/32)
- passenger airbag stage 3 (8/124) (XC90 USA/CDN only)
- seat belt tensioners front and rear (8/33, 8/34 8/55, 8/56 and 8/62)
- seat belt tensioners third row (8/94 and 8/95) (XC90 7 seater only)
- side impact sensors (7/108, 7/109, 7/115 and 7/116)
- left and right inflatable curtains (8/66 and 8/67)
- left and right rear inflatable curtains (8/96 and 8/97) (XC90 7 seater only)
- SIPS bags (8/51 and 8/52)
- front impact sensors (7/178 and 7/179) (certain markets and models only)
- front seat belt buckles (3/93 and 3/94)
- adaptive steering column (8/99) (XC90 USA/CDN only)
- switch on/off, front passenger airbag (3/157) (not USA/CDN)
- occupant weight sensor (OWS) (7/93) (certain markets and models only)

The supplemental restraint system module (SRS) transmits information via the controller area network (CAN) to the driver information module (DIM) (5/1) indicating that this test is in progress. The central electronic module (CEM) (4/56) also transmits the parameter values during the status check.

The driver information module (DIM) then lights the SRS indicator lamp. The SRS indicator lamp is lit while the supplemental restraint system (SRS) is being checked. When the supplemental restraint system (SRS) has been tested and no faults have been detected, the SRS indicator lamp goes out.

If a fault is detected during the check it will be indicated in one of the following ways, depending on how serious it is:

- the SRS indicator lamp continues to light and a warning text is displayed in the driver information module (DIM)
- the general warning lamp lights and a warning text is displayed in the driver information module (DIM).

The driver information module (DIM) continuously transmits a signal to the supplemental restraint system module (SRS) via the controller area network (CAN) with information about whether the SRS indicator lamp is working or not. The general warning lamp will light and a text message will be displayed in the driver information module (DIM) if the SRS warning lamp is not working. If the CAN communication between the supplemental restraint system (SRS) module and the driver information module (DIM) fails, the red lamp in the general warning lamp lights up and text is displayed in the driver information module (DIM). If the faults

disappear and the driver information module (DIM) can transmit information to the supplemental restraint system module (SRS) and the status of the SRS warning lamp is OK, the warning lamps will return to normal function.

SIDE IMPACT

Fig. 79: Identifying Side Impact / SRS System Communication Links & Components
Courtesy of VOLVO CARS CORPORATION

In event of a side-on collision, the side impact sensors (7/108, 7/109, 7/115 and 7/116) on the left and right-hand sides evaluate the force of the collision pulse. If the collision pulse is powerful enough, the level of the acceleration signal from the side impact sensors will exceed the calculated activation level for the collision protection system in the supplemental restraint system module (SRS) (4/9).

The control module also requires a further acceleration sensor, either from the acceleration sensors in the control module or from another side impact sensor. If the signal from the collision sensor meets the conditions for activation of the side impact airbags (8/51 and 8/52) and/or inflatable curtains (8/66 and 8/67) (8/96 and 8/97 on the 7 seater XC90 only), the control module sends a current pulse to those side impact airbags and/or inflatable curtains that are to be deployed. The side impact protection system will only be deployed on the side where the impact is registered.

The activation level of the side impact protection system depends on the vehicle speed and whether any of the front doors are open during the collision. The central electronic module (CEM) (4/56) transmits information about vehicle speed on the controller area network (CAN). The rear electronic module (REM) (4/58) transmits

information about the status (open or closed) of the left and right-hand front doors.

The control module also transmits a collision signal on a directly connected cable to the central electronic module (CEM) and the phone module (PHM) (16/60), so that these control modules can take certain actions.

A collision status signal is also sent to the phone module (PHM) and the central electronic module (CEM) via the controller area network (CAN).

A function known as multi-point detection is used during a head-on collision. This means that the impact pulse is registered in several points. This function is integrated in the supplemental restraint system module (SRS) (4/9). The front impact sensors (7/178 and 7/179) (certain markets and models only) is also part of multi-point detection in the control module. The front impact sensors register the impact pulse and send acceleration data to the control module.

When the collision pulse is sufficiently large an activation signal (current pulse) is transmitted to one or more of the following:

- front airbags stages 1 and 2 (8/30, 8/31, 8/32 and 8/61)
- front airbags stage 3 (8/123 and 8/124) (XC90 USA/CDN only)
- seat belt tensioners (8/33, 8/34, 8/55 8/56 and 8/62)
- seat belt tensioners third row (8/94 and 8/95) (XC90 7 seater only).

In vehicles with an on/off switch for the front passenger airbag (3/157), the passenger airbag will not be activated if it has been switched off.

In cars with an occupant weight sensor (OWS) (7/93), this is used to activate and deactivate the passenger airbag.

For cars with an adaptive steering column (8/99), when the driver's airbag is activated and the driver seatbelt is fastened, an activation signal (current pulse) is transmitted by the control module to the adaptive steering column.

A collision signal is transmitted on a direct connection from the supplemental restraint system module (SRS) to the central electronic module (CEM) (4/56) and phone module (PHM) (16/60) when the collision protection system is activated. These two control modules ensure that:

- the central locking system is unlocked
- the fuel pump (FP) is switched off
- the interior lighting lights
- the hazard warning signal flashers are activated
- the collision pulse is registered
- an automatic alarm is sent to CSC (customer service center) if the vehicle is equipped with Volvo On Call (Plus).

A collision status signal is also sent to the phone module (PHM) and the central electronic module (CEM) via the controller area network (CAN).

ROLL OVER PROTECTION (XC90 ONLY)

Fig. 81: Identifying Roll Over Protection Components
Courtesy of VOLVO CARS CORPORATION

If the side tilt of the car exceeds 50 - 55 degrees, the supplemental restraint system module (SRS) starts calculating the strength of the rotational energy. If the sideways lean and rotational energy are high enough, the control module will activate the roll over protection. All seat belt tensioners in the car, front (8/33, 8/34), rear (8/55, 8/56, 8/62) and for the third row of seats (8/94, 8/95) (7 seater XC90 only) will be activated. The front (8/66, 8/67) and rear (8/96, 8/97 (7 seater XC90 only)) inflatable curtains will also be activated.

A collision signal is transmitted on a direct connection from the supplemental restraint system module (SRS) to the central electronic module (CEM) (4/56) and phone module (PHM) (16/60) when the collision protection system is activated. These two control modules ensure that:

- the central locking system is unlocked
- the fuel pump (FP) is switched off
- the interior lighting lights
- the hazard warning signal flashers are activated
- the collision pulse is registered
- an automatic alarm is sent to CSC (customer service center) if the vehicle is equipped with Volvo On Call (Plus).

A collision status signal is also sent to the phone module (PHM) and the central electronic module (CEM) via the controller area network (CAN).

ACTIVATING/DEACTIVATING THE FRONT PASSENGER AIRBAG (NOT USA/CDN)

Fig. 82: Identifying Front Passenger Airbag Activation / Deactivation Communication Links & Components
Courtesy of VOLVO CARS CORPORATION

If necessary, the front passenger airbag (8/31 and 8/32) can be deactivated. This is done using a switch (3/157) positioned on the side of the dashboard on the passenger side.

If the position of the switch is changed from "on" to "off", the level of current at the two Hall sensors connected to the switch changes. The Hall sensors transmit the altered current levels to the supplemental restraint system module (SRS) (4/9) via directly connected cables.

The control module software deactivates the front passenger airbag, which means that the airbag has no functionality in the event of a collision. The supplemental restraint system module (SRS) transmits a signal on the controller area network (CAN) to the upper electronic module (UEM) (4/70), with a request to light the passenger airbag disconnected warning lamp. The upper electronic module (UEM) then lights the passenger airbag disconnected warning lamp.

When the position of the switch is changed from "off" to "on", a new current level is transmitted from the Hall sensors to the supplemental restraint system module (SRS). The control module software then activates the airbag, which means that the airbag has full functionality in the event of a collision. At the same time, the supplemental restraint system module (SRS) transmits a signal on the controller area network (CAN) to the upper electronic module (UEM), with a request to switch off the passenger airbag disconnected warning lamp. The upper electronic module (UEM) then switches off the passenger airbag disconnected warning lamp.

NOTE: The on/off switch for the front passenger airbag and occupant weight sensor (OWS) must not be installed in the vehicle together.

ACTIVATING/DEACTIVATING FRONT PASSENGER AIRBAG (USA/CDN - CERTAIN MODELS ONLY)

Fig. 83: Identifying Occupant Weight Sensor (OWS) System Communication Links & Components
Courtesy of VOLVO CARS CORPORATION

Under normal conditions the information from the occupant weight sensor (OWS) system (7/93) is the basis for whether the supplemental restraint system module (SRS) (4/9) should activate or deactivate the front passenger airbag (8/31 8/32 and 8/124). The occupant weight sensor (OWS) communicates continuously with the supplemental restraint system (SRS) module on the local LIN bus. When a passenger weighing more than a certain weight is in the seat, the supplemental restraint system module (SRS) is informed by the occupant weight sensor (OWS). The control module software activates the front passenger airbag, which means that the airbag has full functionality in the event of a collision. At the same time the supplemental restraint system module (SRS) transmits a signal on the controller area network (CAN) to the upper electronic module (UEM) (4/70), with a request to switch off the passenger airbag disconnected warning lamp. The upper electronic module (UEM) then switches off the passenger airbag disconnected warning lamp.

If the weight on the front passenger seat is below a certain level the supplemental restraint system module (SRS) is informed by the occupant weight sensor (OWS). The control module software deactivates the front passenger airbag, which means that the airbag has no functionality in the event of a collision. At the same time the supplemental restraint system module (SRS) transmits a signal on the controller area network (CAN) to the upper electronic module (UEM), with a request to switch on the passenger airbag disconnected warning lamp. The upper electronic module (UEM) then lights the passenger airbag disconnected warning lamp. However there is an exception to this:

- The passenger airbag disconnected warning lamp will remain unlit if the occupant weight sensor (OWS) registers that the passenger seat is unoccupied. This means that the passenger airbag is deactivated.

NOTE: The on/off switch for the front passenger airbag and occupant weight sensor (OWS) must not be installed in the vehicle together.

THE OCCUPANT WEIGHT SENSOR (OWS) SYSTEM (USA/CDN - CERTAIN MODELS ONLY)

The occupant weight sensor (OWS) is designed to meet the regulatory requirements of Federal Motor Vehicle Safety Standard (FMVSS) 208 and is designed to disable (will not inflate) the passenger's side front airbag

under certain conditions.

The occupant weight sensor (OWS) works with sensors that are part of the front passenger's seat and safety belt. The sensors are designed to detect the presence of a properly seated occupant and determine if the passenger's side front airbag should be enabled (may inflate) or disabled (will not inflate).

The occupant weight sensor (OWS) will disable (will not inflate) the passenger's side front airbag when:

- the front passenger seat is unoccupied, or there are small/medium objects in the front passenger seat,
- the system determines that an infant is present in a rear-facing infant seat that is installed according to the manufacturer's instructions,
- the system determines that a small child is present in a forward-facing child restraint that is installed according to the manufacturer's instructions,
- the system determines that a small child is present in a booster seat,
- a front passenger takes his/her weight off of the seat for a period of time,
- a child or a small person occupies the front passenger seat.

The occupant weight sensor (OWS) uses a passenger airbag warning lamp (PAD) which will illuminate and stay lit to remind you that the passenger's side front airbag is disabled. The passenger airbag warning lamp (PAD) is located in the interior rear view mirror.

NOTE: The passenger airbag warning lamp (PAD) will illuminate for a short period of time when the ignition is turned on to confirm it is functional.

When the front passenger seat is not occupied (empty seat) or in the event that the passenger's side front airbag is enabled (may inflate), the passenger airbag warning lamp (PAD) will be unlit.

The occupant weight sensor (OWS) is designed to disable (will not inflate) the passenger's side front airbag when a rear facing infant seat, a forward-facing child restraint, or a booster seat is detected. The passenger airbag warning lamp (PAD) will illuminate and stay lit to remind you that the passenger's side front airbag is disabled.

NOTE: Volvo recommends that children always be properly restrained in appropriate child restraints in the rear seats.

In rare situations when the safety belt is not latched, some child restraints may not be detected by the OWS because there is very little weight on the vehicle seat cushion. In these cases the passenger's side front airbag may be disabled, but the passenger airbag warning lamp (PAD) will not be lit. **Do not assume that the passenger's side front airbag is disabled unless the passenger airbag warning lamp (PAD) is lit.**

The occupant weight sensor (OWS) is designed to enable (may inflate) the passenger's side front airbag anytime the system senses that a person of adult size is sitting properly in the front passenger seat. The passenger airbag warning lamp (PAD) will be unlit and stay unlit.

The occupant weight sensor (OWS) detects pressure on the front passenger seat cushion as a result of load put in the seat. The occupant weight sensor (OWS) classifies the occupant as small or large based on whether the

induced pressure is below or above a predetermined threshold. The threshold is defined between the pressure induced by children and the pressure induced by adults in accordance with the regulatory requirements of Federal Motor Vehicle Safety Standard (FMVSS) 208. If the occupant weight sensor (OWS) determines a small occupant classification, the passenger's side front airbag will be disabled and the passenger airbag warning lamp (PAD) will be lit. If the occupant weight sensor (OWS) determines a large occupant classification, the passenger's side front airbag will be enabled and the passenger airbag warning lamp (PAD) will be unlit.

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 84: Locating Supplemental Restraint System (SRS) Control Module
Courtesy of VOLVO CARS CORPORATION

The supplemental restraint system module (SRS) handles functions for:

- seat belt tensioners
- side impact sensors
- front impact sensor (certain markets and models only)
- seat position sensors (XC90 USA/CDN only)
- side impact protection (SIPS) bags
- front driver and passenger airbags
- inflatable curtains
- SRS indication
- passenger airbag indication
- collision output signal
- collision registration
- adaptive steering column (XC90 USA/CDN only)
- front seat belt buckles
- switch on/off, front passenger airbag (not USA/CDN)
- occupant weight sensor (OWS) (certain markets and models only)

The control module is in the transmission tunnel, between the gear selector lever and the parking brake.

The supplemental restraint system module (SRS) communicates with directly connected components and with other control modules via the Controller Area Network (CAN).

The control module checks the input and output signals through an integrated diagnostic system. A diagnostic trouble code (DTC) is stored if the control module detects a fault.

Any diagnostic trouble codes (DTCs) are stored in the control module memory. The data can be read off using VIDA (Volvo scan tool).

The control module can process multiple collisions, frontal collisions, collisions from behind, side-on collisions and overturning.

The control module function can be easily checked by switching on the ignition. The SRS indicator lamp in the combined instrument panel must light up when the key is in ignition positions I-III. The lamp goes out after a short while if no faults are detected. This means that the supplemental restraint system (SRS) is functioning correctly.

SIGNALS

The table below summarizes the input signals to and output signals from the supplemental restraint system module (SRS). The signal types are divided into directly connected signals, LIN and CAN communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: • Side impact sensor left C-post (7/108) • Side impact sensor right C-post (7/109) • Side impact sensor left B-post (7/115) • Side impact sensor right B-post (7/116) • Front impact sensor, front left (7/179) (certain markets and models only) • Front impact sensor, front right (7/178) (certain markets and models only) • Seat belt buckle left front (3/93) • Seat belt buckle right front (3/94) • Switch on/off, front passenger airbag (3/157) (not USA/CDN).	**Directly connected:** • Central electronic module (CEM) (4/56), collision output signal • Phone Module (PHM) (16/60), collision output signal • Seat belt tensioner left front (8/33) • Seat belt tensioner right front (8/34) • Seat belt tensioner left rear (8/55) • Seat belt tensioner right rear (8/56) • Seat belt tensioner center rear (8/62) • Seat belt tensioner third row left (8/94) (XC90 7 seater only) • Seat belt tensioner third row right (8/95) (XC90 7 seater only) • Adaptive steering column (8/99) (XC90 USA/CDN only) • Airbag passenger front stage 1 (8/31) • Airbag passenger front stage 2 (8/32)

	• Passenger airbag front stage 3 (8/124) (XC90 USA/CDN only) • Airbag driver front stage 1 (8/30) • Airbag driver front stage 2 (8/61) • Driver airbag front stage 3 (8/123) (XC90 USA/CDN only) • Side impact protection (SIPS) bag left front (8/51) • Side impact protection (SIPS) bag right front (8/52) • Left inflatable curtain (8/66) • Right inflatable curtain (8/67) • Inflatable curtain left rear (8/96) (XC90 7 seater only) • Inflatable curtain right rear (8/97) (XC90 7 seater only).
Via LIN communication (certain markets and models only): • Occupant weight sensor (OWS) (7/93).	**Via LIN communication (certain markets and models only):** • Occupant weight sensor (OWS) (7/93).
Via Controller Area Network (CAN) communication: • Central electronic module (CEM) (4/56) • Driver information module (DIM) (5/1) • Upper electronic module (UEM) (4/70) • Rear electronic module (REM) (4/58).	**Via Controller Area Network (CAN) communication:** • Central electronic module (CEM) (4/56) • Driver information module (DIM) (5/1) • Phone module (PHM) (16/60) • Upper electronic module (UEM) (4/70)

SUPPLEMENTAL RESTRAINT SYSTEM MODULE (SRS) (2003-2004)

DESIGN

CONTROL MODULE

Fig. 86: Locating Supplemental Restraint System (SRS) Control Module
Courtesy of VOLVO CARS CORPORATION

WARNING: The ignition must be switched off before any work is carried out on the supplemental restraint system (SRS). The airbags could accidentally deploy if the ignition is switched on.

The primary task of the supplemental restraint system module (SRS) is to minimize injuries to the driver and passengers in different types of accident. To do this, the control module validates incoming pulsed collision signals (acceleration signals generated by a collision) and then determines the required action. The control module uses internal sensors as well as external collision sensors. Using the data collected from the sensors, the system determines which of the following will be activated:

- front airbags
- side impact protection (SIPS) bags
- inflatable curtains
- seat belt tensioners.

The collision sensor in the control module registers the longitudinal mechanical stress that occurs in a frontal collision. A side impact may also be registered in the collision sensor. Front-rear stresses are gauged by two acceleration sensors. Two frontal collision sensors are also used to register stresses in the event of a frontal collision. If the longitudinal stresses exceed a certain level, the stress will be calculated (the collision pulse). The calculation evaluates whether the collision pulse was sufficient to activate the airbags and/or the seat belt tensioners. Airbags and seat belt tensioners can be activated individually.

The control module is also able to register when the car is about to roll over. If the sideways tilt and rotational energy of the car exceed a certain level, the control module begins a calculation to determine whether the roll over protection should be activated. The critical tilt angle is 50-55 degrees. All seat belt tensioners and inflatable curtains are deployed if the roll over protection is activated.

The driver and passenger airbags and the seat belt tensioners are designed to deploy in the event of a frontal collision.

When the collision protection system is activated, the control module transmits a pulsed current to the ignition mechanisms in the airbags and/or the seat belt tensioners. No seat belt tensioners or airbags will be activated in the event of a collision from the rear.

Two requirements need to be fulfilled in order for the side impact protection system to be activated:

1. that the collision pulse is sufficiently high that a trigger signal is sent from the side impact sensor to the control module
2. the control module or another collision sensor transmits a confirmation signal which allows the collision protection system to be deployed.

The side impact protection system is deployed when the control module has received both an activation and a confirmation signal.

If the side impact occurred at the front of the vehicle the side airbags and the inflatable curtain are deployed on the side that received the impact. If the side impact is towards the rear of the car, only the inflatable curtains are deployed on that side.

The control module has a collision recording function. This records certain system information in the event of a collision. If necessary, this information can be analyzed and used after a collision. This data is used in ongoing development of collision safety systems.

In the event of a collision a collision signal is transmitted from the supplemental restraint system module (SRS) to the carphone module (PHM) and the central electronic module (CEM) using a directly connected cable. The purpose of the signal is to switch off the fuel pump, light the interior lighting, unlock the doors and to transmit an automatic alarm to the Customer Service Center (if the car is equipped with Volvo On Call (Plus)) in the event of a collision. This also applies in the event of a collision from the rear.

A collision signal is also sent to the phone module (PHM) and the rear electronic module (REM) via the controller area network (CAN).

The supplemental restraint system module (SRS) either deploys the airbags or the seat belt tensioners. This depends on whether:

- if the driver and front passenger are wearing seat belts or not
- if there is a fault in the side impact sensor or the connection to the side impact sensor
- if there is a fault in the seat belt buckles
- if Controller area network (CAN) communication is not working.

As a result of the above conditions, in the event of a low speed collision the seat belt tensioner may deploy on the driver's side whilst the airbag is deployed on the passenger side.

The SRS indicator lamp lights when the ignition is switched on. If no faults are registered by the control module, either internally or from the sensors, wiring or igniters, a signal is transmitted on the controller area network (CAN) to the driver information module (DIM) confirming that the SRS indicator lamp can be switched off. If there is a fault, the supplemental restraint system module (SRS) transmits information to the driver information module (DIM) indicating which lamp should be lit and the text to be displayed in the combined instrument panel.

The driver information module (DIM) continuously transmits information to the supplemental restraint system (SRS) control module via the controller area network (CAN) about the status of the SRS indicator lamp.

If the SRS indicator lamp stops functioning, the orange or red light in the general warning lamp is used instead.

Note that after a collision, it may be necessary to replace the wiring for the airbags and seat belt tensioners which deployed. This is because the connectors may melt at the moment of deployment. If a connector has melted, the wiring adjacent to it must be replaced.

WARNING: The ignition must be switched off before any work is carried out on the supplemental restraint system (SRS). The airbags could accidentally deploy if the ignition is switched on.

SIDE IMPACT SENSOR

Fig. 87: Locating Side Impact Sensors
Courtesy of VOLVO CARS CORPORATION

The side impact sensors in the car are used to measure and evaluate the collision pulses. An assessment is then transmitted to the supplemental restraint system module (SRS).

The sensors which are used in the car are:

- 2 side impact sensors in the B-post
- 2 side impact sensors in the C-post.

The side impact sensors have integrated logic. In the event of a collision, they determine whether the impact was large enough to warrant transmitting an activation signal to the control module to deploy the side impact airbag. Only the side impact protection on the side from which the activation signal was sent can be deployed.

The side impact sensors transmit continuous OK signals to the control module to indicate that they are working. In the event of a fault in the side impact sensor, a fault signal is transmitted to the control module which then stores a diagnostic trouble code (DTC). A diagnostic trouble code (DTC) is also stored when the control module has not received an OK signal. Each side impact sensor has a software ID. The ID is used to check that the correct side impact sensor is installed. This is because the activation level of the signal which is transmitted to the control module is not necessarily the same for the different side impact sensors.

The front (B-post) and rear (C-post) side impact sensors are a different color and have different coding on their connectors to simplify installation.

The front side impact sensors cannot be installed in place of the rear sensors and vice versa.

Data transmission occurs on the same cable used for power supply, i. e. one cable to each side impact sensor.

FRONTAL IMPACT SENSOR

Fig. 88: Locating Frontal Impact Sensor
Courtesy of VOLVO CARS CORPORATION

The car's frontal impact sensors are used to provide the supplemental restraint system module (SRS) with accurate advanced information about the collision pulse. This enables the supplemental restraint system module (SRS) to determine more accurately the components to be activated.

The frontal impact sensors have integrated logic which transmits acceleration data to the supplemental restraint system module (SRS).

The frontal impact sensors transmit continuous OK signals to the control module to indicate that they are working. In the event of a fault in a frontal impact sensor, a fault signal is transmitted to the control module which then stores a diagnostic trouble code (DTC). A diagnostic trouble code (DTC) is also stored when the control module has not received an OK signal. Each frontal impact sensor has a software ID. The ID is used to check that the correct frontal impact sensor is installed.

Data is transmitted on the cable used for power supply, i. e. there is one cable for each frontal impact sensor.

The two frontal impact sensors are under the left and right-hand headlamps.

FRONT AIRBAGS

Driver airbag

Fig. 89: Driver Airbag
Courtesy of VOLVO CARS CORPORATION

Front passenger airbag

Fig. 90: Front Passenger Airbag
Courtesy of VOLVO CARS CORPORATION

WARNING: **Never use an ohmmeter or similar tool to test airbags, inflatable curtains or seat belt tensioners. Disconnect airbags, inflatable curtains or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.**

The airbags at the front of the car are:

- driver airbag - 2 stage deployment
- front passenger airbag - 2 stage deployment.

The front airbags have two ignition components each. These are electrically separated from each other. This means that the different ignition components have their own separate power supply and grounding points from the control module. Two power supply outputs are required from the control module for each airbag. That is one output for each ignition component. This means that in total four pins on the control module, two power supply pins and two ground pins, are used for each airbag.

When activating the airbags electrical signals are transmitted from the supplemental restraint system module (SRS) to the relevant airbag stage.

Stage 1

Stage 1 of the driver's airbag is pyrotechnic. In the event of activation the charge combusts and the gas which develops is blown into the airbag.

Stage 1 on the passenger airbag consists of a pyrotechnic component in combination with a reservoir which stores a gas. On activation the pyrotechnic charge and mixes with the stored gas. The gas mixture is blown into the airbag.

Stage 2

Stage 2 of the driver's and passenger airbags is pyrotechnical. In the event of activation the charge combusts and the gas which develops is blown into the airbag.

The pace of the airbag 2 stage activation is dependent on collision type and seat belt use. Both stages activate but in the event of a lesser impact, there is a greater time delay between stage 1 and stage 2. For more serious impacts the time delay is shorter between stages 1 and 2.

The driver's airbag is located in the steering wheel. The passenger airbag is located above the glove compartment in the dashboard.

WARNING: **Never use an ohmmeter or similar tool to test airbags, inflatable curtains or seat belt tensioners. Disconnect airbags, inflatable curtains or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.**

SIDE IMPACT AIR BAGS

Fig. 91: Identifying Side Impact Air Bags
Courtesy of VOLVO CARS CORPORATION

WARNING: **Never use an ohmmeter or similar tool to test airbags, inflatable curtains or seat belt tensioners. Disconnect airbags, inflatable curtains or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.**

There are two side impact protection (SIPS) bags connected to the supplemental restraint system module (SRS). Their connectors are electrically separated from each other. The side impact protection (SIPS) bags are on the outside of the front seats. The side impact protection (SIPS) bags deploy on the side of the impact. Their task is to protect the upper body in the event of a side on collision.

The side airbags together with the inflatable curtains and other safety systems can help to protect the driver and front passenger in the event of a collision.

The side impact protection (SIPS) bag uses a pyrotechnic component in combination with a reservoir which stores a gas. On activation the pyrotechnic charge and mixes with the stored gas. The gas mixture is blown into the airbag.

WARNING: **Never use an ohmmeter or similar tool to test airbags, inflatable curtains or seat belt tensioners. Disconnect airbags, inflatable curtains or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.**

FRONT, REAR AND THIRD ROW SEAT BELT TENSIONERS

Fig. 92: Locating Seat Belt Tensioners
Courtesy of VOLVO CARS CORPORATION

WARNING: **Never use an ohmmeter or similar tool to test airbags, inflatable curtains or seat belt tensioners. Disconnect airbags or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.**

There are up to seven seat belt tensioners in the car, two in the front, three on the rear seat and two on the third row if applicable. They contain an explosive charge which tensions the seat belts when deployed. The seat belt tensioners are separated from each other electrically. This means that each seat belt tensioner has a separate individual power supply and ground from the control module.

The front seat belt buckles are directly connected to the supplemental restraint system module (SRS). This means that data indicating whether the seat belts are engaged or not is transmitted directly to the supplemental restraint system module (SRS).

The seat belt tensioner tensions the seat belt to reduce the forward movement of the body. This also reduces the forces on the chest from the airbag and seat belt. Each seat has a seat belt tensioner.

The supplemental restraint system module (SRS) determines whether to deploy the seat belt tensioners based on whether the seat belts are being used. The seat belt tensioner will not be activated if the seat belt is not engaged. However, if the control module reads off incorrect data for the front seat belt buckles, the seat belt tensioners will be activated and the air bag will be deployed. Deployment of the airbags occurs in the same way as when the seat belts are not fastened.

The seat belt tensioner consists of a pyrotechnical charge and a cylinder with a piston. The piston is connected to a steel cable which is secured to the seat belt reel. When the control module activates the seat belt tensioner the piston is forced downwards by the expanding gas. The piston pulls in the steel cable which reels in the belt.

WARNING: **Never use an ohmmeter or similar tool to test airbags, inflatable curtains or seat belt tensioners. Disconnect airbags or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.**

INFLATABLE CURTAINS

Fig. 93: Identifying Inflatable Curtains
Courtesy of VOLVO CARS CORPORATION

WARNING: **Never use an ohmmeter or similar tool to test airbags, inflatable curtains or seat belt tensioners. Disconnect airbags or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.**

There are up to four inflatable curtains connected to the supplemental restraint system module (SRS). Their connectors are electrically separated from each other.

The inflatable curtains are located in the roof between the A and D-posts. The front and rear inflatable curtains have only one ignition component each. The task of the inflatable curtain is to protect the head and the upper body in the event of a side impact. The supplemental restraint system module (SRS) deploys the inflatable curtains on the side from which the side impact sensors transmitted an activation signal.

The number of inflatable curtains in the car depends on whether the car is a 5 or 7 seater model. The configuration is as follows:

- 5 seater models: There is a front inflatable curtain on each side, two in total
- 7 seater models: There are front and rear inflatable curtains on each side, four in total.

The inflatable curtain uses a pyrotechnic component in combination with a reservoir which stores a gas. On activation the pyrotechnic charge and mixes with the stored gas. The gas mixture is blown into the inflatable curtain which falls and covers the side windows and B post. If rear inflatable curtains are installed the C post is also covered.

Where there are two inflatable curtains per side, these are always activated simultaneously.

WARNING: Never use an ohmmeter or similar tool to test airbags, inflatable curtains or seat belt tensioners. Disconnect airbags or seat belt tensioners before testing them. Failure to do so may result in accidental deployment. This could result in serious injury or death.

SRS INDICATION

The supplemental restraint system module (SRS) checks the system once every second. A diagnostic trouble code (DTC) is stored and the SRS indicator lamp lights if the same fault is detected 10 times in one ignition cycle.

SRS indication is partially via the SRS indicator lamp which changes between red and orange depending on how serious the fault is and partially via a text message display. The SRS indicator lamp lights when the ignition is switched on. If no faults are registered by the control module, either internally or from the sensors, wiring or igniters, a signal is transmitted on the controller area network (CAN) to the driver information module (DIM) confirming that the SRS indicator lamp can be switched off. If no faults are detected when the ignition is switched on, the lamp will remain lit for 7 seconds. The lamp goes out when the system has been checked and is operating without faults. If a fault is detected in the supplemental restraint system module (SRS), the SRS indicator lamp lights and a text message is displayed in the text box. Information about which lamp should be lit is transmitted by the supplemental restraint system module (SRS) on the controller area network (CAN).

The control module has an EEPROM memory which retains data about diagnostic trouble codes (DTCs) even when the battery has been disconnected.

The driver information module (DIM) continuously indicates to the supplemental restraint system module (SRS) whether the SRS indicator lamp is working or not. If the lamp stops working, the general warning lamp lights up and a text message is displayed in the text box.

NOTE: Never take a resistance reading across the airbags or seat belt tensioners if a diagnostic trouble code (DTC) is stored for too high or low igniter resistance. Special tools with the same resistance as the airbag or seat belt tensioner must be used for fault-tracing.

SEAT BELT BUCKLE

Fig. 94: Locating Seat Belt Buckles
Courtesy of VOLVO CARS CORPORATION

The two front seat belt buckles have hall sensors and are connected to the SRS module. These connections are electrically separated from each other.

The hall sensor detects whether the belt is engaged in the seat belt buckle or not and indicates this to the supplemental restraint system module (SRS).

This data is used to set the activation level of the airbags and to determine whether or not the seat belt tensioners need to be activated. If a fault is detected in the seat belt buckles or in the terminal for the seat belt buckles, the activation level of both the driver and passenger airbags is set as if the occupant is not wearing a seat belt. The seat belt tensioner will still function as if the occupant is wearing a seat belt however.

DEPLOYING AIRBAGS / SEAT BELT TENSIONERS

The collision safety system is extremely advanced. It is able to adapt airbag deployment and the activation of the seat belt tensioners to suit the specific circumstances of a collision. In general it is extremely unlikely that all airbags and seat belt tensioners will be deployed in the same accident. It is possible that only one airbag or seat belt tensioners is deployed. This is determined by the supplemental restraint system module (SRS) based on the forces that occur during the collision.

If the control module deploys the front airbags, both stages will always be activated. By varying the time between the two deployment phases, the deployment of the airbag is more gentle for a low speed collision.

ACTIVATION LEVELS FOR AIRBAGS AND SEAT BELT TENSIONERS

The table below shows how the SRS system reacts in the event of a frontal impact.

NOTE: The deployment of the driver and passenger airbags is calculated individually.

Level 1 = Low speed collision

Level 5 = Severe collision

Collision level	Front seats		Rear seat / Rear seat 3rd row
	Seat belt not in use	Seat belt in use	
Level 1	No action	The seat belt tensioner is activated. The airbags are not deployed.	No action
Level 2	The seat belt tensioner is not activated. The airbags are deployed with a slow build-up of pressure.	The seat belt tensioner is activated. The airbags are not deployed.	No action
Level 3	The seat belt tensioner is not activated. The airbags are deployed with a slow build-up of pressure.	The seat belt tensioner is activated. The airbags are deployed with a slow build-up of pressure.	The seat belt tensioner is activated.
Level 4	The seat belt tensioner is not activated. The airbags are deployed with a rapid build-up of pressure.	The seat belt tensioner is activated. The airbags are deployed with a slow build-up of pressure.	The seat belt tensioner is activated.
Level 5	The seat belt tensioner is not activated. The airbags are deployed with a rapid build-up of pressure.	The seat belt tensioner is activated. The airbags are deployed with a rapid build-up of pressure.	The seat belt tensioner is activated.

DEPLOYMENT OF SIDE IMPACT PROTECTION (SIPS) BAGS

The table below shows how the SRS system reacts in the event of a side impact.

	Side impact sensor, left-hand side		Side impact sensor, right-hand side	
	B-post	**C-post**	**B-post**	**C-post**
Left-hand (SIPS) bag	X			
Left-hand inflatable curtain, front and rear	X	X		
Right-hand SIPS bag			X	
Right-hand inflatable curtain, front and rear			X	X

DIAGNOSTIC FUNCTIONS

OVERVIEW

Fig. 95: Identifying Supplementary Restraint System Diagnostic Functions
Courtesy of VOLVO CARS CORPORATION

The on-board diagnostic (OBD) system for the supplemental restraint system module (SRS) continually diagnoses the function of supplemental restraint system components and stores any diagnostic trouble codes (DTCs). The diagnostic trouble codes (DTCs) can then be read off via VIDA (Volvo scan tool). The principle behind VIDA information presentation is the same as for other on-board diagnostic (OBD) systems.

FAULT INDICATION

The driver is warned in a number of ways via the combined instrument panel if any fault occurs in the supplemental restraint system:

- SRS warning lamp and text in the display
- the general warning lamp lights up in red and there is text in the display
- the general warning lamp lights up in orange and there is text in the display.

A VIDA station must be connected to the car data link connector (DLC) in order for a fault source to be identified.

DIAGNOSTIC TROUBLE CODES (DTCS)

The control module will store a diagnostic trouble code (DTC) if it detects a fault. The control module can store

up to 10 diagnostic trouble codes (DTCs).

If a fault disappears for any reason after the diagnostic trouble code (DTC) has been stored in the control module, information about the fault remains in the control module. If a fault is no longer permanent the diagnostic trouble code (DTC) remains as intermittent.

READING AND ERASING DIAGNOSTIC TROUBLE CODES (DTCS)

Stored diagnostic trouble codes (DTCs) can be read off and erased using this function.

After the diagnostic trouble code (DTC) is stored it can also be read off if the fault is still present (permanent fault), or if the fault has disappeared for any reason (intermittent fault).

Diagnostic trouble codes (DTCs) can only be erased when all diagnostic trouble codes (DTCs) have been read at least once.

DATA READ-OUT

Data can be read off from the supplemental restraint system module (SRS) using this function.

Car model

Reads off the model that is programmed into the control module.

Steering

Read off whether the supplemental restraint system module (SRS) is programmed for left or right-hand drive.

Passenger airbag

Read off the configuration that is programmed into the supplemental restraint system module (SRS), with or without passenger airbag.

Front seat belt buckle

Reads off the status of the driver and passenger seatbelt buckles.

READING OFF THE CONTROL MODULE IDENTIFICATION

VIDA identifies the control modules by reading off a number of codes from the control module memory.

The codes contain information about the control module's:

- hardware P/N (control modules without software)
- hardware serial number (control modules without software)
- side impact sensor serial number
- software P/N

- P/N diagnostic software.

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software for the supplemental restraint system module (SRS) can be downloaded. When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module.

If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

When the control module is replaced, the new control module will not have any preprogrammed software.

The type of information which is downloaded is parameter files containing:

- vehicle type
- right / left hand drive
- parameters unique to this model
- whether the car has a passenger airbag or not
- a signal configuration file.

The MOST network is used for a total software reload.

FUNCTION

CHECKING THE SRS SYSTEM

Fig. 96: Identifying SRS System Components
Courtesy of VOLVO CARS CORPORATION

When the ignition key is turned from 0 to I, II or III, the status of the internal functions in the supplemental restraint system module (SRS) (4/9) is checked, as well as all directly connected components such as:

- driver airbags (8/30 and 8/61)
- passenger airbags (8/31 and 8/32)
- seat belt tensioners (8/33, 8/34, 8/55, 8/56, 8/62, 8/94, 8/95)
- side impact sensors (7/108, 7/109, 7/115 and 7/116)
- front and rear inflatable curtains (8/66, 8/67, 8/96, 8/97)
- SIPS bags (8/51 and 8/52)
- frontal impact sensor (7/178, 7/179)
- front seat belt buckles (3/93, 3/94).

At the same time, the supplemental restraint system module (SRS) transmits data via the Controller area network (CAN) to the driver information module (DIM) (5/1) indicating that this test is in progress. The central electronic module (CEM) (4/56) also transmits the parameter values during the status check.

The driver information module (DIM) then lights the SRS indicator lamp. The SRS indicator lamp is lit while the SRS system is being checked. When the SRS system has been tested and if no faults have been detected, the SRS indicator lamp goes out.

If a fault is detected, the lamp remains lit and a warning text is displayed in the text box in the combined instrument panel. The driver information module (DIM) continuously transmits a signal to the supplemental restraint system module (SRS) via the Controller area network (CAN) with information about whether the SRS indicator lamp is working or not. The orange general warning lamp lights up if the SRS indicator lamp stops working. If this lamp also stops working, the red general warning lamp is used. If the CAN communication between the supplemental restraint system (SRS) module and the driver information module (DIM) fails, the red lamp in the general warning lamp lights up and text is displayed in the text box in the combined instrument panel. If the fault disappears and the driver information module (DIM) is again able to transmit information to the supplemental restraint system module (SRS) indicating that the status of the SRS indicator lamp is OK, the general warning lamp will not light but the SRS indicator lamp will take over.

It may take up to 3 minutes before the seat belt buckles indicate whether they are functioning correctly.

SIDE IMPACT

Fig. 97: Identifying Side Impact Components
Courtesy of VOLVO CARS CORPORATION

In event of a side-on collision, the side impact sensors in the left (7/108 and 7/115) and right-hand (7/109 and 7/116) sides evaluate the force of the collision pulse. If the collision pulse is powerful enough, an activation

signal for the collision protection system is transmitted to the SRS (supplemental restraint system) (4/9).

The control module also requires a confirmation signal, either from the acceleration sensors in the control module or from another side impact sensor. If the pulse from the collision sensor meets the conditions for activation of the SIPS bags (8/51 and 8/52) and inflatable curtains (8/66, 8/67, 8/96 and 8/97), the control module sends a current pulse to those SIPS bags or inflatable curtains that are to be deployed. The side impact protection system will only be deployed on the side where the impact is registered.

The control module also transmits a collision signal on the directly connected cable to the central electronic module (CEM) (4/56) and the phone module (PHM) (16/60), so that these control modules can take certain actions.

A collision status signal is also sent to the phone module (PHM) and rear electronic module (REM) (4/58) on the Controller Area Network (CAN).

FUNCTION IN THE EVENT OF A FRONTAL IMPACT

Fig. 98: Identifying Frontal Impact Components
Courtesy of VOLVO CARS CORPORATION

In the event of frontal collision a function called multi point detection is used. The collision pulse is registered at several points. This function is integrated in the supplemental restraint system module (SRS) (4/9) and is called a collision sensor. When the collision pulse is sufficiently large an activation signal (current pulse) is transmitted to the front airbags and/or the seat belt tensioners. The frontal collision sensors (7/178, 7/179) are also part of multi point detection in the control module. They register the collision pulse and transmit acceleration data to the control module indicating the size of the collision pulse. The driver (8/30, 8/61) and front passenger (8/31, 8/32) airbags are deployed. The seat belt tensioners for the front (8/33, 8/34), rear (8/55, 8/56 and 8/62) and third row of seats (8/94, 8/95) are activated.

When the collision protection system has been activated a collision signal is transmitted from the supplemental restraint system module (SRS) (4/9) to the central electronic module (CEM) (4/56) and phone module (PHM) (16/60) on a directly connected cable. These two control modules ensure that:

- the central locking system is unlocked
- the fuel pump (FP) is switched off
- the interior lighting is lit
- the warning lamps are lit
- the collision pulse is registered
- an automatic alarm is sent to CSC (customer service center), and to Volvo On Call (Plus) if applicable.

ROLL OVER PROTECTION

Fig. 99: Identifying Roll Over Protection Components

Courtesy of VOLVO CARS CORPORATION

If the side tilt of the car exceeds 50 - 55 degrees, the supplemental restraint system module (SRS) starts calculating the strength of the rotational energy. If the sideways lean and rotational energy are high enough, the control module will activate the roll over protection. All seat belt tensioners in the car, front (8/33, 8/34), rear (8/55, 8/56, 8/62) and for the third row of seats (8/94, 8/95) (if applicable) will be activated. The front (8/66, 8/67) and rear (8/96, 8/97) inflatable curtains will also be activated.

When the collision protection system has been activated a collision signal is transmitted from the supplemental restraint system module (SRS) (4/9) to the central electronic module (CEM) (4/56) and phone module (PHM) (16/60) on a directly connected cable. These two control modules ensure that:

- the central locking system is unlocked
- the fuel pump (FP) is switched off
- the interior lighting is lit
- the warning lamps are lit
- the collision pulse is registered
- an automatic alarm is sent to CSC (customer service center), and to Volvo On Call (Plus) if applicable.

A collision status signal is also sent to the phone module (PHM) and rear electronic module (REM) (4/58) on the Controller Area Network (CAN).

SYSTEM OVERVIEW

SUPPLEMENTAL RESTRAINT SYSTEM MODULE (SRS)

Fig. 100: Locating Supplemental Restraint System (SRS) Control Module
Courtesy of VOLVO CARS CORPORATION

The primary task of the supplemental restraint system module (SRS) is to manage the following functions:

- seat belt tensioners
- side impact sensors
- frontal collision sensors

- side impact protection (SIPS) bags
- front driver and passenger airbags
- inflatable curtains
- SRS indication
- collision output signal
- collision registration.

The control module is in the transmission tunnel, between the gear selector lever and the parking brake.

The supplemental restraint system module (SRS) communicates with directly connected components and with other control modules via the Controller Area Network (CAN).

The control module checks the input and output signals through an integrated diagnostic system. A diagnostic trouble code (DTC) is stored if the control module detects a fault.

Any diagnostic trouble codes (DTCs) are stored in the control module memory. The data can be read off using VIDA (Volvo scan tool).

The control module can process multiple collisions, frontal collisions, collisions from behind, side-on collisions and overturning.

The control module function can be easily checked by switching on the ignition. The SRS indicator lamp in the combined instrument panel must light up when the key is in ignition positions I-III. The lamp goes out after a short while if no faults are detected. This means that the supplemental restraint system (SRS) is functioning correctly.

SIGNALS

The table below summarizes the input signals to and output signals from the supplemental restraint system module (SRS). The signal types are divided into directly connected signals and Controller area network (CAN) communication. The illustration below displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: • Side impact sensor left C-post (7/108) • Side impact sensor right C-post (7/109) • Side impact sensor left B-post (7/115) • Side impact sensor right B-post (7/116) • Frontal collision sensor left front (7/179) • Frontal collision sensor right front (7/178) • Seat belt buckle left front (3/93) • Seat belt buckle right front (3/94).	**Directly connected:** (power supply unless otherwise stated) • Central electronic module (CEM) (4/56), collision output signal • Phone Module (PHM) (16/60), collision output signal • Seat belt tensioner left front (8/33) • Seat belt tensioner right front (8/34) • Seat belt tensioner left rear (8/55) • Seat belt tensioner right rear (8/56)

	• Seat belt tensioner center rear (8/62) • Airbag passenger front stage 1 (8/31) • Airbag passenger front stage 2 (8/32) • Airbag driver stage 1 (8/30) • Airbag driver stage 2 (8/61) • Side impact protection (SIPS) bag left front (8/51) • Side impact protection (SIPS) bag right front (8/52) • Inflatable curtain left front (8/66) • Inflatable curtain right front (8/67) • Inflatable curtain left rear (8/96) • Inflatable curtain right rear (8/97) • Seat belt tensioner third row left (8/94) • Seat belt tensioner third row right (8/95).
Via Controller Area Network (CAN) communication: • Central electronic module (CEM) (4/56) • Driver information module (DIM) (5/1) • Rear electronic module (REM) (4/58).	**Via Controller Area Network (CAN) communication:** • Central electronic module (CEM) (4/56) • Driver information module (DIM) (5/1) • Phone module (PHM) (16/60) • Rear electronic module (REM) (4/58).

Fig. 101: Identifying Volvo Component Designations.

THE CONTROLLER AREA NETWORK (CAN) (2003-2004)

CAN-NETWORK (CONTROLLER AREA NETWORK)

OVERVIEW

CAN (Controller Area Network) is a standardised system for multiplex-communication. Volvo has developed a new standard for multiplex communication - VOLCANO. VOLCANO is a further development of CAN and operates with real time operation and prioritising. The description of prioritising is developed from VOLCANO but is designated CAN.

The standard for Control area network (CAN) specifies:

- That two cables should be used (CAN H and CAN L)
- Which voltage levels should be used
- What a message should look like
- How transfer errors should be handled.

CABLES, CAN H AND CAN L

Fig. 102: CAN H And CAN L Distributing Signals Within Multiplex Communication Network
Courtesy of VOLVO CARS CORPORATION

The CAN H and CAN L cables must not be confused with HS CAN and LS CAN which are speeds on the Controller area network. CAN H and CAN L are a way of distributing signals within the multiplex communication network.

Communication occurs through two cables. These two cables are paired together. CAN H is always white and CAN L is always green.

The cables are made of copper and are easily identified by the green and white colouring.

The voltage levels for communication occur using differential voltage levels.

The reason for communicating using paired cables and differential voltage levels is that the network becomes less sensitive to interference.

The same message is transferred simultaneously by both cables, but different voltage levels are used.

- Binary 1 = 2.5 V on both CAN H and CAN L.

- Binary 0 = 4 V on CAN H and 1 V on CAN L.

Average voltage level is 2.5V.

CONTROLLER AREA NETWORK (CAN) MESSAGE

Fig. 103: Controller Area Network Message
Courtesy of VOLVO CARS CORPORATION

The message consists of the following components:

- Identifier ("flag"), which indicates the message identity and prioritisation
- Data information (value, information etc.)
- Check sum, used to check that the message has arrived correctly
- Stop signal, which indicates that the message has finished.

A complete Controller area message is called a frame.

PRIORITISING

Conflicts can occur in a network when several control modules wish to send a message at the same time. For example when the driver presses the brake pedal at the same time as the passenger changes the climate control settings and a passenger in the rear seat opens the power window.

For safe function the messages must be prioritised. In addition the time delays which occur in the event of a queue situation must be held with reasonable limits. This is so that the customer does not experience the system as slow.

To solve problems with conflicts and time delays there is a priority order of messages to ensure good functionality.

Prioritisation of messages is determined by the number of zeroes at the beginning of a message, the more zeroes the higher the priority.

Prioritisation occurs as follows:

- When the network is available all the control modules with "something to say" send bit one in their message
- All the control modules detect what has been transmitted on the network
- If a control module has transmitted 0 those that have sent 1 stop and wait until the next time the network is available

- Those that transmitted 0 transmit bit two of the message
- If a control module has transmitted 0 as bit two those that have sent 1 stop and wait until the next time the network is available and so on.

The message with the highest priority (most zeroes at the beginning) "wins" and is sent first.

The end of a message is seven zeroes. The control modules then know that the network is available and a new message can be sent in priority order.

TWO TYPES OF MESSAGE

There are two types of message in the system:

- Periodical frames. These messages are sent regularly and give the present status of a parameter. They are used for information which is frequently updated, speed signals for example
- Event frames, which are only sent when predetermined conditions have been met. This type of message is used for things that seldom occur, raising / lowering a window for example.

The message can contain an update bit which states how "fresh" the information is.

The system assumes that the receiver has received the message so an acknowledgement is not sent (a reply is only sent to a direct question from another control module).

But the receiver knows how often it should receive a message about which status applies. If the message is missing the receiver can connect an emergency program and / or set a diagnostic trouble code.

COMPATIBILITY

The units must "speak" the same language and must be compatible with each other. A standardised communication protocol is used for this.

Signal configuration (sfg) contains the language between the units. If any module has a signal configuration which does not correspond to other units the module cannot communicate. This means that all the units must have compatible signal configuration. The signal configuration is occasionally modified so that the new messages are added and old messages removed.

CONFIGURATION

Instructions for the following are downloaded when a system is configured:

- Which control modules are included in the system (for example central electronic module, and others.)
- Which control module should do what (for example "you are the control module for the passenger door - you are the control module for the driver's door")
- Which functions should be included (for example if the alarm function should be on or off)
- Which components are connected to the control modules (for example whether the inclination sensor is included in the alarm or not)

- Which messages a control module is to transmit and which it is to receive
- Where the different data should be stored.

The configuration must be adapted after installation of accessories and must be downloaded again after any control module is replaced. The configuration is adapted and downloaded via VIDA (Volvo scan tool).

NOTE: Even if two cars appear identical, they may behave differently because of differing configurations, a parameter may have been modified by, e. g., the customer or workshop.

CONTROL MODULES IN THE CONTROL AREA NETWORK (CAN)

CONTROL MODULES

Fig. 104: Controller Area Network Components
Courtesy of VOLVO CARS CORPORATION

The number of control modules in the CAN varies depending on the level of equipment, the car model and the structure week. The description applies to the structure week 199815-200149. The structure week and the manufacture week are not necessarily the same week. The week of manufacture is the week in which the car was manufactured in the factory. The content of the car is guided by the structure week A structure week can extend over many manufacture weeks. The structure week is specified in the format YYYYWW.

For example, the structure week 199815 indicates that the structure week of the car is week 15 1998.

Explanation		
LS CAN	=	CAN Low speed section (125 Kbps)
HS CAN	=	CAN High speed section (250 Kbps)
Serial	=	Serial communication (Volcano Lite) between the slave control module and the Controller area network (CAN) control module (10.4 Kbps).
Slave control module	=	A control module with low computing power which is connected to a main "control module" and which only operates on commands from the main control module.
Option	=	Accessories installed at the factory to order, when purchasing a new car.
Accessories	=	After market installations.

Control module	Name/ Function	Communication	Other
ABS	Anti-Lock Brake System Module. Controls the brake system ABS/EBD/DSTC/STC functions and communicates with the other modules via the network high speed sector. Contains a terminating resistor for the network. Replaced by the brake control module from structure week 200135 inclusive.	HS CAN	Replaced by the brake control module from structure week 200135 inclusive.
AEM	Accessory Electronic Module. Controls certain accessory functions for the car. The control module communicates with other control modules via the low speed sector of the network.	LS CAN	Accessories
Audio control module	AUdio Module. Controls the radio / audio equipment and communicates with the other modules via the network low speed sector.	LS CAN	Standard/ accessory/option.
Brake control module	Brake Control Module Controls the ABS/EBD/DSTC/STC functions of the brake system and communicates with the other modules via the network high speed sector. Contains a terminating resistor for the	HS CAN	Replaces the ABS control module from structure week 200135.

	network. Replaces the ABS control module from structure week 200135.		
Climate control module	Climate Control Module Controls the climate control system functions and communicates with the other modules via the network low speed sector.	LS CAN	STD/ MCC/ ECC
Central electronic module	Central Electronic Module Is the network main control module and the interface between the high and low speed sides. The control module has a comprehensive function in the electrical system and handles a large number of functionalities.	HS CAN/ LS CAN	
Additional heater module	Combustion Preheater Module	Serial Start the parking heater. The combustion preheater module is a slave control module for the central electronic module and communicates serially.	Option /accessory. Market dependent Slave control module for the central electronic module (CEM).
Driver's door module	Driver Door Module Controls the drivers door functions and communicates with the other modules via the network low speed side.	LS CAN	
DEM	Differential Electronic Module Controls four wheel drive engagement and communicates with the other modules via the network high speed side.	HS CAN	Option from structure week 200135 inclusive.
Driver information module	Driver Information Module Controls the combined instrument panel functions and communicates	LS CAN	

	with the other modules via the network low speed side.		
Engine control module (ECM)	Engine Control Module Controls the engine functions and communicates with the other modules via the network high speed side. Contains a terminating resistor for the high speed side on the network for those engines which do not have an electronic throttle module.	HS CAN	Different versions depending on the engine alternative.
Electronic throttle module	Electronic Throttle Module	HS CAN Controls the throttle and communicates with the other modules via the network high speed side. Contains a terminating resistor for the high speed side on the network.	Gasoline engines only. A design change has been introduced structure week 200135 on certain gasoline engines. The electronic throttle module has been replaced by a new type of electronic throttle which does not communicate using the controller area network (CAN).
GSM	Gear Selector Module	Serial Transmits and receives information about the position of the gear selector and the lighting strength in the gear selector. The gear selector module is a slave control module for the transmission control module (TCM) and communicates serially.	Slave control module for the transmission control module (TCM). Applies to cars with automatic transmission only.
Inclination Sensor Module	Inclination Sensor Module	Serial	Option /accessory. Slave control module for the rear electronic module (REM).

	Used for the alarm, transmits information about the angle of the vehicle. The inclination sensor module is a slave control module for the rear electronic module and communicates serially.		
LSM	Light Switch Module Transmits information about the light switch beam level adjustment and rheostat positions, and status of the switches. The light switch module is a slave control module for the central electronic module and communicates serially.	Serial	Slave control module for the central electronic module (CEM).
Mass Movement Sensor	Mass Movement Sensor Module Used for the alarm, transmits information about movement in the passenger compartment The mass movement sensor module sensor is a slave control module for the upper electronic module and communicates serially.	Serial	Option /accessory. Slave control module for the upper electronic module.
Passenger door module	Passenger Door Module Controls the functions in the passenger side door and communicates with the other modules via the network low speed side.	LS CAN	
Carphone module	PHone Module Controls the functions of the carphone and communicates with the other modules via the network low speed side.	LS CAN	Option /accessory.
Power seat module	Power Seat Module	LS CAN Controls the positions and functions of the driver's seat. Communicates with other control	Standard/ option **NOTE:** **Power seat module (PSM) does not check the seat heating and SIPS (side impact protection system)**

		modules via the low speed side on the network.	**airbag function.**
Rear electronic module	Rear Electronic Module Controls the electrical functions in the rear section of the car, and communicates with the other modules via the low speed side on the network. Contains a terminating resistor for the network.	LS CAN	
RTI (road traffic information)	Road Traffic Information Module Controls the road traffic information functions and communicates with the other modules via the low speed side on the network.	LS CAN	Option /accessory
Steering angle sensor	Steering Angle Sensor Module Collects information about the steering angle and communicates with other control modules using the high speed side on the network.	HS CAN	Option. Used in the DSTC system.
Siren control module	Siren Control Module Controls the siren and functions. The siren control module is a slave control module for the upper electronic module and communicates serially.	Serial	Option /accessory. Slave control module for the upper electronic module.
SRM	Sun Roof Module Controls the sun roof and functions. The sun roof control module is a slave control module for the upper electronic module and communicates serially.	Serial	Option. Slave control module for the upper electronic module.
SRS (supplemental restraint system)	Supplemental Restraint System Module Controls the crash safety system and communicates with the other modules	LS CAN	

	via the low speed side on the network.		
Steering wheel module	Steering Wheel Module Receives signals from the switch in the steering wheel and the controls around the steering wheel. Communicates with other control modules via the low speed side on the network.	LS CAN	
Transmission control module (TCM)	Transmission Control Module Controls the automatic transmission and communicates with the other modules via the high speed side on the network.	HS CAN	Applies to cars with automatic transmission only.
Upper electronic module	Upper Electronic Module	LS CAN Controls the electrical functions in the upper section of the passenger compartment. Communicates with other control modules via the low speed side on the network. Contains a terminating resistor for the network.	Included in the rear view mirror. **NOTE:** **There are two versions of the upper electronic module. One with automatic anti-glare function and one without. The two versions cannot be interchanged.**

ERROR MANAGEMENT IN THE CONTROLLER AREA NETWORK (CAN)

OVERVIEW

The Controller area network (CAN) is monitored and controlled by the central electronic module. When the central electronic module detects a fault in the controller area network a diagnostic trouble code (DTC) is set in the central electronic module. There are different diagnostic trouble codes depending on the type of malfunction detected.

Types of error which are handled are:

- Electrical faults
- No communication from the control module
- Faulty communication.

ELECTRICAL FAULTS

In the event of errors in the signal levels on the communication cables for the central electronic module a diagnostic trouble code (DTC) is stored in the central electronic module. A check is carried out on each communication cable to the central electronic module, CAN L, CAN H on the low speed side and CAN L and CAN H on the high speed side There are two different levels which are detected (low or high).

This gives eight diagnostic trouble codes for detecting electrical faults.

The diagnostic trouble codes for electrical faults are CEM-DF0X for the low speed network and CEM-DF1X for high speed network.

NO COMMUNICATION FROM THE CONTROL MODULE

The central electronic module knows which control modules are in the Controller area network and checks that all the control modules communicate. If any control module on the Controller area network (CAN) does not communicate a diagnostic trouble code is stored in the central electronic module. There is a diagnostic trouble code for each control module. The diagnostic trouble codes are CEM-1A5X respectively CEM-1A6X.

FAULTY COMMUNICATION

Each control module except for the central electronic module has two diagnostic trouble code types which are related to faulty communication (the central electronic module only has one type of diagnostic trouble code).

These are:

- Faulty messages
- Configuration fault (missing in the central electronic module (CEM)).

Faulty messages

When a control module sends errors in the messages a number of times, the control module stops communication. The diagnostic trouble code is stored in the control module which caused the faulty message. If the fault is permanent it is impossible to communicate with the control module. It is not possible to read off diagnostic trouble codes from the control module with the switched off communication.

The diagnostic trouble codes (DTCs) are XXX-E000 for the high speed network and XXX-E001 for low speed network.

Configuration fault

If the signal configuration of a control module does not correspond to the signal configuration of the central electronic module, a diagnostic trouble code is stored in the control module with the faulty signal configuration.

The diagnostic trouble code for configuration fault is XXX-E003.

THE NETWORK

OVERVIEW

Increasing demands for further functionality in the car, both by statutory requirement and customers, have led to an increased complexity in the car.

This has in turn driven the development of more flexible electronic systems. The Controller area network (CAN) is a result of this research. The network allows a large number of different commands and messages to be transmitted and received on the same cable. Previously each command or message required a separate cable. By using the network functionality has increased without increasing the number of cables.

The number of commands and messages that can be handled by the network depends on the speed of the network and the length of the message / command. The Volvo network which is based on a Controller Area Network (CAN), can transmit over 500 different signals and approximately 100 messages (also known as frames). Each message can contain several signals, for example a message to the rear electronic module can contain all the signals for how the tail lamps should be lit.

ADVANTAGES OF A NETWORK

Easier to add further functions and install accessories

Because the control modules in the network are already connected to each other and are easy to add more information to, all that is required is:

- to connect the sensors to the nearest control module
- to connect the controlled component to the nearest control module
- to download software to alter the configuration and programming of the network.

The length of the wiring and the number of components which are introduced with the car are less than previously.

An example of this is the addition of cruise control for the car.

Before the introduction of the network the installation of control modules, switches, vacuum pumps, vacuum servos, hoses and cable harnesses was necessary.

With the network only the installation of a switch and the downloading of software which alters the configuration of the car is required.

Easier to introduce logical functions

Logical functions can be explained as "if this occurs then the following corrective action must be carried out". For example, the system is programmed so that if a tail lamp is broken, a message is transmitted via the Controller area network (CAN) to the driver information module to warn the driver.

All that is required to introduce a logical function is to change the programming of the affected control module - the rear electronic module and driver information module in the example above.

Introduction of logic functions does not increase the number of components or cables.

Easy to adapt the system to customer and market requirements

The functions can be altered depending on the requirements of the customer and market. An example of this could be fog tail lamps. Certain markets use two fog tail lamps, others only use one on the driver's side. Previously it was required that different replacement parts were stored for different markets. Now the same replacement part can be used for all markets, by changing the programming depending on the market.

Similar basic systems can be used for a whole model program

Similar networks (hardware) can be used for a large number of different cars.

The only thing which differentiates the cars is:

- the components (control modules, sensors controlled components etc.) which are connected to the system
- Which components do what
- Which components/functions are standard /optional/accessories
- The configuration /programming of the system.

THE NETWORK CONSTRUCTION

OVERVIEW

The network is made up of a number of control modules (sometimes called nodes)which are connected to each other serially via two communication cables. Each control module is supplied with power and grounded individually and receives messages /commands via the two communication cables. In both networks (high and low speed sides) the control modules are serially connected. In the event of an open-circuit those control modules beyond the open-circuit will not be able to communicate with other parts of the network.

HIGH AND LOW SPEED SIDES ON THE NETWORK

The network consists of two parts. A high speed side which transfers (HS CAN) signals/messages between the central electronic module and the control modules in the engine compartment, and a low speed side (LS CAN) which transfers the signals /messages between the central electronic module and the control modules in the passenger compartment.

The interface between the high and low speed sides is supplied by the central electronic module which speeds up or slows down the communication between the two network sides.

TRANSFER SPEEDS

The Volvo Controller area network (CAN) has two transfer speeds.

- HS CAN (High speed) has a transfer speed of 250 Kbps
- LS CAN (Low speed) has a transfer speed of 125 Kbps.

1 Kbps = 1024 bit per second (1byte = 8 bits).

For serial communication (Volcano Lite) between a control module and a slave control module the transfer speed is 10.4 Kbps.

TERMINATING RESISTOR

To prevent electrical reflections and interference in the Controller area network (CAN) there are terminating resistors which bridge CAN H and CAN L. One in each end point on both the high and low speed side of the network. Each terminating resistor has a resistance of 120 ohm.

- The terminating resistor for the high speed Controller area network (CAN) is positioned in the brake control module/ABS control module and in the engine control module (ECM) or electronic throttle module. The terminating resistor is in the engine control module, on models without an electronic throttle module
- There are terminating resistors for the low speed Controller area network (CAN) in the upper electronic module and the rear electronic module.

Both the terminating resistors create a parallel circuit The following resistors can be measured under specified conditions:

- When the Controller area network (CAN) is intact the resistance in the network is approximately 60 ohm
- In the event of an open-circuit in the wiring, the resistance in the network is approximately 120 ohm
- In the event of a short-circuit between the communication cables the resistance is approximately 0 ohm.

THE CONTROLLER AREA NETWORK (CAN) (2005-2012)

CAN-NETWORK (CONTROLLER AREA NETWORK)

OVERVIEW

CAN (Controller Area Network) is a standardised system for multiplex communication. Multiplex communication means that you can transmit messages between one or more control modules on the same wires without communication between the various control modules disrupting one another. Volvo has produced a new standard for multiplex communication, known as VOLCANO. VOLCANO is a further development of CAN and works with real-time processing, as well as prioritisation. The description of prioritisation is based on VOLCANO but named CAN.

The standard for Control area network (CAN) specifies:

- That two cables should be used (CAN H and CAN L)
- Which voltage levels should be used
- What a message should look like
- How transfer errors should be handled.

CABLES, CAN H AND CAN L

Fig. 105: CAN H And CAN L Distributing Signals Within Multiplex Communication Network
Courtesy of VOLVO CARS CORPORATION

The wires CAN H and CAN L must not be confused with HS CAN and LS CAN, which indicate the speed of the CAN network. CAN H and CAN L are the names for the wires used to distribute the signals in the multiplex communications network.

Communication takes place using two wires. These two wires are twisted together and are made of a copper material.

The voltage levels for communication take place using differential voltage levels. Two twisted-pair wires and differential voltage levels are used because this makes the network less susceptible to interference.

The same message is transferred simultaneously by both cables, but different voltage levels are used.

- Binary 1 = 2.5 V on both CAN H and CAN L.
- Binary 0 = 4 V on CAN H and 1 V on CAN L.

When measured between CAN L and earth, the average voltage level is approx. 2.3 V.

When measuring between CAN H and ground, the average voltage level is approx. 2.8 V. When measuring between the two CAN wires, with normal traffic on the network, the average voltage level is approx. 0.55-0.90 V (up to max. 0.6-1.4 V).

Volvo's CAN-net meets ISO 11898-2. Other standard is 11898-3 where the voltage on CAN H changes from approx. 5 V to approx. 1 V, and CAN L from approx. 0 V to approx. 4 V when changing from logic "0" to logic "1". Other standard is SAE J2411 where only one cable is used for CAN-communication.

CONTROLLER AREA NETWORK (CAN) MESSAGE

Fig. 106: Controller Area Network Message

Courtesy of VOLVO CARS CORPORATION

The message consists of the following components:

- Identifier ("flag"), which indicates the message's identity and priority.
- Data information (value, information, etc.).
- Check sum, used to check that the message has arrived correctly
- Stop signal, which indicates that the message has finished.

A complete CAN-message is called a frame.

PRIORITISING

Conflicts can occur in a network when several control modules wish to send a message at the same time. For example when the driver presses the brake pedal at the same time as the passenger changes the climate control settings and a passenger in the rear seat opens the power window.

For safe function the messages have to be prioritised. In addition the time delays which occur in case of queue situations must be held within reasonable limits. This is so that the customer does not experience the system as "sluggish" or slow.

To solve problems with conflicts and time delays there is a priority order of messages to ensure good functionality.

Prioritisation of messages is determined by the number of zeroes at the beginning of a message, the more zeroes the higher the priority.

Prioritisation occurs as follows:

- When the network is available, all the control modules that have "something to say" send bit one in their message.
- All the control modules detect what has been transmitted on the network
- If a control module has transmitted 0 those that have sent 1 stop and wait until the next time the network is available
- Those that transmitted 0 transmit bit two of the message
- If a control module has transmitted 0 as bit two those that have sent 1 stop and wait until the next time the network is available and so on.

The message with the highest priority (most zeroes at the beginning) "wins" and is sent first.

The end of a message is seven zeroes. The control modules then know that the network is available and a new message can be sent in priority order.

TWO TYPES OF MESSAGE

There are two types of message in the system:

- **Periodical frames** . These messages are sent regularly and give the status of a parameter. They are used for information which is frequently updated, speed signals for example.
- **Event frames** , which are only sent when predetermined conditions have been met. This type of message is used for things that seldom occur, raising / lowering a window for example.

The message can contain an update bit which states how "fresh" the information is.

The system assumes that the receiver has received the message so an acknowledgement is not sent (a reply is only sent to a direct question from another control module).

However, the receiver "knows" how often it should receive a message about which status applies. If the message is missing, the receiver can connect an emergency program and/or generate a diagnostic trouble code.

Diagnostic trouble codes (DTCs) can also be stored if the receiving control module does not "understand" the message it has received. Examples of this may include intermittent short-circuits between one of the CAN wires and voltage or earth.

QUALITY FACTOR

In a distributed system where information (signals) is sent between different control modules in a network, it is usually the control module that generates/creates information (the signal) that knows the quality of the information that is sent. To be able to inform receiving control modules about the quality of information, a quality factor (Q-factor) is sent over the network at the same time as the information (signal). The quality factor describes status of the information (signal). For example, if the signal is defective due to a faulty sensor, a receiving control module can use the quality factor to decide if the control module shall take any action (e. g., reconfiguration).

The quality factor can be of the following status:

- **Ok**

  The value indicates that the signal is normal and shows a credible status and accuracy.

- **Outside specified range**

  Even though the value indicates that the signal is normal and may be usable, some fault has been detected that indicates that accuracy has been reduced so that performance may be affected or instability can occur.

- **No data found**

  The value indicates that the signal has its initial start-up value and has not yet had time to receive measured or calculated value. This may occur when the control module's start-up process is not completely finished. As soon as the control module has started, the signal shall have a correct value. Receiving control module has a built-in delay to wait for correct signal.

- **No data exists**

The value indicates that the signal is faulty. This prevents the signal from being used by receiving control modules.

SUMMARY OF QUALITY FACTOR THAT MAY APPLY.

Sending control module	Receiving control module and its function	
Status	"Common" control module	Control module with high demand for accuracy
Ok	Normal function	Normal function
Outside specified range *	Normal function	Controlled limitation of performance may occur *
No data found	Normal function	Normal function
No data exists *	Limited or lost performance/lost function *	Limited or lost performance/lost function *

* Diagnostic trouble code may be stored.

COMPATIBILITY

The units must "speak" the same language and must be compatible with each other. A standardised communication protocol is used for this.

Signal configuration (sfg) contains the language between the modules. If any module has a signal configuration which does not tally with other modules, this module is unable to communicate with other modules. This means that all modules must have compatible signal configuration. The signal configuration is sometimes changed as new messages are added and old ones are deleted.

CONFIGURATION

Instructions for the following are downloaded when a system is configured:

- Which control modules are included in the system (for example central electronic module (CEM), and others.)
- Which control module should do what (for example "you are the control module for the driver's door - you are the control module for the passenger door")
- Which functions should be included (for example if the alarm function should be on or off)
- Which components are connected to the control modules (for example whether the inclination sensor is included in the alarm or not)
- Which messages a control module is to transmit and which it is to receive
- Where the different data should be stored.

In the central electronic module (CEM), information is stored on which control modules are installed in this particular vehicle. This information is stored and retrieved from Volvo's central database when software is downloaded. The central electronic module (CEM) also contains information on which primary signal configuration is to be used in the vehicle. Information on the vehicle's signal configuration must be stored in all

control modules connected to the CAN network so that they can communicate in the first place.

The signal configuration is a part of the software downloaded after a control module is fitted or replaced. When software is loaded to a control module, the information in the control module indicating, for example, that a new accessory has been connected is updated automatically.

Once software has been downloaded, some values may be changed according to the customer's requirements, for example whether lamp indication upon locking or unlocking the vehicle should be active, or the dip degree of the interior rear view mirror. These settings may disappear when new software is downloaded.

Software is downloaded via the Software Manager.

NOTE: Even if two vehicles appear identical they may behave differently due to differing configurations, a parameter may have been modified by, e. g., the customer or workshop.

CONSTRUCTION OF THE NETWORK

OVERVIEW

The network is made up of a number of control modules (sometimes called nodes)which are connected to each other serially via two communication cables. Each control module is supplied with power and grounded individually and receives messages /commands via the two communication cables. In both networks (high and low speed sides) the control modules are serially connected. In the event of an open-circuit those control modules beyond the open-circuit will not be able to communicate with other parts of the network.

HIGH AND LOW SPEED SIDES ON THE NETWORK

Fig. 107: CAN Network Diagram
Courtesy of VOLVO CARS CORPORATION

The network consists of two parts: a high speed side (HS CAN) which transmits signals/messages between the

central electronic module (CEM) and control modules mainly in the engine compartment, and a low speed side (LS CAN) which transmits signals/messages between the central electronic module (CEM) and control modules in the passenger compartment and the luggage compartment.

The interface between the high and low speed sides is supplied by the central electronic module (CEM) which converts the transmission speed up or down for communication between the two network sides.

DATA LINK CONNECTOR

Fig. 108: Identifying CAN Data Link Connector & Terminals
Courtesy of VOLVO CARS CORPORATION

The data link connector is located in the passenger compartment near the driver's station, cables for high-speed side (HS CAN) and low-speed side (LS CAN) are connected to the data link connector.

Fig. 109: Identifying Standardized Pins On OBD II-Connector
Courtesy of VOLVO CARS CORPORATION

- Pin 3 LS CAN (low-speed side) (H-cable)
- Pin 4 Chassis ground
- Pin 5 Signal ground
- Pin 6 HS CAN (high-speed side) (H-cable)
- Pin 11 LS CAN (low-speed side) (L-cable)

- Pin 14 HS CAN (high-speed side) (L-cable)
- Pin 16 Voltage feed

NOTE: The data link connector's other connections may be used by other functions. This section only decribes connections related to CAN.

TRANSFER SPEEDS

The Volvo Controller area network (CAN) has two transfer speeds.

- HS CAN (high speed) has a transfer rate of 500 kbit/s.
- LS CAN (low speed) has a transfer rate of 125 kbit/s.

1 kbit/s = 1024 bits per second (1 byte = 8 bits).

For serial communication (Volcano Lite) between a control module and a slave control module the transfer rate is 10.4 kbit/s.

There is another serial standard known as LIN. This is an international standard which is becoming more commonly used. Its function is almost identical to that of Volcano Lite. The difference is in the communication method and rate. The transfer rate for LIN is 9.6 kbit/s.

TERMINATING RESISTOR

High-speed net HS CAN (High Speed), example

Fig. 110: Identifying HS CAN (High Speed) Functional Block Diagram
Courtesy of VOLVO CARS CORPORATION

Low-speed net LS CAN (Low Speed), example

Fig. 111: Identifying LS CAN (Low Speed) Functional Block Diagram
Courtesy of VOLVO CARS CORPORATION

To prevent electrical reflections and interference in the CAN network, there are terminating resistors which bridge CAN H (High) and CAN L (Low), one at each end (main line) on both the high and low speed sides of the network. Each terminating resistor has a resistance of 120 ohm

- For HS CAN (high speed), the terminating resistors are located in the brake control module (BCM) and the engine control module (ECM).
- For LS CAN (low speed), the terminating resistors are located in the upper electronic module (UEM) and the rear electronic module (REM).

Resistance measurement of parallel circuit with terminating resistor

Both the terminating resistors create a parallel circuit The following resistors can be measured under specified conditions:

- When the CAN network is intact, the resistance on the network is approx. 60 ohm.
- In case of open circuits on the cables, so that 1 terminating resistor is not included in the circuit, the resistance in the net is approx. 120 ohm (only one main line is measured)
- An open circuit on the cables to control modules located "outside" the measured circuit cannot be detected with this measurement.
- In case of short-circuiting between the communication cables, the resistance is approx. 0 ohm between the cables, regardless of where the short-circuiting is located.

RESISTANCE MEASUREMENT IN HIGH-SPEED NET HS CAN (HIGH SPEED), EXAMPLE

Fig. 112: Checking Resistance In CAN Lines

CONTROL MODULES IN THE CONTROL AREA NETWORK (CAN)

Fig. 114: Identifying Controller Area Network Components
Courtesy of VOLVO CARS CORPORATION

The number of control modules in the CAN network varies depending on the car model, equipment level and structure week, The structure week and construction week are not necessarily the same week. The construction week is the week in which the vehicle is built in the factory. The content of the vehicle is steered towards structure week. A structure week may extend over a number of construction weeks. Structure weeks are specified in the format YYYYWW.

For example, structure week 199815 indicates that the structure week of the vehicle is week 15, year 1998.

NOTE: **To troubleshoot respective CAN-net, see troubleshooting for CAN-related diagnostic trouble codes for Central electronic module (CEM). For example, choose any of CEM-DF01 - DF17 depending on CAN-net.**

Explanation		
LS CAN	=	CAN Low Speed Section (125 kbit/s)
HS CAN	=	CAN High Speed Section (500 kbit/s)
Serial	=	Serial communication (Volcano Lite) between the slave control module and the CAN control module (10.4 kbit/s). LIN (9.6 kbit/s).
Slave control module	=	A control module with low computing power which is connected to a main "control module" and which only operates on commands from the main control module.

Option	=	Accessories installed at the factory to order, when purchasing a new car.
Accessories	=	Aftermarket installation.

Control module	Name/ Function	Network	Miscellaneous
AEM	Accessory electronic module (AEM) Controls certain accessory functions for the vehicle, This control module communicates with other control modules via the low speed side of the network.	LS CAN	Accessories
Audio control module	Audio module (AUM) Controls the radio / audio equipment and communicates with the other modules via the network low speed sector.	LS CAN	Standard/ accessory/option.
Brake control module	Brake control module (BCM) Controls the ABS/EBD/DSTC/STC functions of the brake system and communicates with the other modules via the network high speed sector. Contains a terminating resistor for the network.	HS CAN	
Climate control module	Climate control module (CCM) Controls the climate control system functions and communicates with the other modules via the network low speed sector.	LS CAN	STD/ MCC/ ECC
Central electronic module	Central electronic module (CEM) This is the network's main control module and the interface between the high and low speed sides. The control module has a comprehensive function in the electrical system and handles a large number of functions.	HS CAN/LS CAN	
DDM	Driver door module (DDM) Controls the drivers door functions and communicates with the other modules via the network low speed side.	LS CAN	
DEM	Differential electronic module (DEM) Controls four wheel drive engagement and communicates with the other modules via the network high speed side.	HS CAN	Option.
Driver information module	Driver information module (DIM) Controls the combined instrument panel functions and communicates with the other modules via the network low speed side.	LS CAN	
ECM	Engine control module (ECM) Controls the engine's functions and	HS CAN	Different versions depending on the engine

	communicates with other control modules via the high speed side of the network. Contains a terminating resistor for the high speed side of the network.		alternative.
ICM	Infotainment control module (ICM) Controls the radio, navigation and telephone functions. This is the primary unit for communication with the units in the MOST network.	LS CAN	XC90 only.
PDM	Passenger door module (PDM) Controls the functions in the passenger side door and communicates with the other modules via the network low speed side.	LS CAN	
Carphone module	Phone module (PHM) Controls the functions of the carphone and communicates with the other modules via the network low speed side.	LS CAN	Option /accessory.
Power seat module	Power seat module (PSM) Controls the positions and functions of the driver's seat. Communicates with other control modules via the low speed side on the network.	LS CAN	Standard/ option **NOTE:** **The power seat module (PSM) does not check seat heating and SIPS (side impact protection system) airbag function.**
REM	Rear electronic module (REM) Controls the electrical functions in the rear section of the vehicle, and communicates with the other modules via the low speed side on the network. Contains a terminating resistor for the network.	LS CAN	
RTI	Road traffic information module (RTI) Controls the road traffic information functions and communicates with the other modules via the low speed side on the network.	LS CAN	Option /accessory
Steering angle sensor	Steering wheel angle sensor module (SAS) Collects information about the steering angle and communicates with other control modules using the high speed side on the network.	HS CAN	Option. Used in the DSTC system.
SRS	Supplemental restraint system module (SRS) Controls the vehicle's crash safety system	LS CAN	

	and communicates with the other modules via the low speed side on the network.		
SUM	Suspension module (SUM) This control module handles the Four-C (Continuously Controlled Chassis Concept) function, i. e. constantly regulates damping in the shock absorbers. Communicates with other control modules via the high speed side on the network.	HS CAN	Option. Not XC90.
TCM	Transmission control module (TCM) Controls the automatic gearbox and communicates with the other modules via the high speed side on the network.	HS CAN	Vehicles with automatic transmission only.
Upper electronic module	Upper electronic module (UEM) Controls the electrical functions in the upper part of the passenger compartment. Also includes remote control receivers. Communicates with other control modules via the low speed side on the network. Contains a terminating resistor for the network.	LS CAN	Included in the interior rear view mirror. **NOTE:** **There are two types of upper electronic module (UEM): one with an automatic dip function, and one without.**

ERROR MANAGEMENT IN THE CONTROLLER AREA NETWORK (CAN)

OVERVIEW

The CAN network is monitored by the central electronic module (CEM). When the central electronic module (CEM) detects a fault in the CAN network, a diagnostic trouble code (DTC) is stored in the central electronic module (CEM). There are various types of diagnostic trouble code (DTC), depending on the type of fault.

Types of error which are handled are:

- Electrical faults
- No communication from the control module
- Faulty communication.

NOTE: **To troubleshoot respective CAN-net, see troubleshooting for CAN-related diagnostic trouble codes for Central electronic module (CEM). For example, choose any of CEM-DF01 - DF17 depending on CAN-net.**

ELECTRICAL FAULTS

When there is a fault in the signal levels on the communication wire to the central electronic module (CEM), a diagnostic trouble code (DTC) is stored in the central electronic module (CEM). Each individual

communication wire to the central electronic module (CEM), CAN L and CAN H on the low speed side of the network and CAN L and CAN H on the high speed side of the network, is checked. There are two different levels detected on each wire: short-circuit to voltage or short-circuit to earth. As the central electronic module (CEM) can also determine when a short-circuit on one or more wires takes place, the control module can also detect a short-circuit between the two CAN wires in the same part of the network.

This gives eight diagnostic trouble codes for detecting electrical faults.

HINT: The central electronic module (CEM) is unable to store diagnostic trouble codes (DTCs) for open-circuits on the CAN wires. Other diagnostic trouble codes (DTCs) may, however, be stored on account of this.

NO COMMUNICATION FROM THE CONTROL MODULE

The central electronic module (CEM) knows which control modules should be present in the CAN network and checks at regular intervals to ensure that all control modules are communicating. If any control module in the CAN network is not communicating, a diagnostic trouble code (DTC) is stored in the central electronic module (CEM). There is a specific diagnostic trouble code (DTC) for every control module in the CAN network.

FAULTY COMMUNICATION

Every control module, apart from the central electronic module (CEM), has two diagnostic trouble code (DTC) types which relate to faulty communication (the central electronic module (CEM) has only one diagnostic trouble code (DTC) type).

These are:

- Faulty messages
- Configuration error (not present on the central electronic module (CEM)).

Diagnostic trouble code (DTC) for faulty configuration is missing from the Central electronic module (CEM) since the control module is always the main control module in the network.

Faulty messages

When a control module transmits faulty signals in its messages a number of times, the control module shuts down communication. This is referred to as the control module going to "Bus-off". A diagnostic trouble code (DTC) is stored in the control module that transmitted faulty messages, and the control module stops communicating on the CAN network. This is done so that the control module does not interfere with other communication on the CAN network. If the fault is permanent, it is not possible to communicate with the control module and there is no chance of reading diagnostic trouble codes (DTCs) from the control module that has shut down communication as long as the control module continues to be powered. If the control module which stored a diagnostic trouble code (DTC) is powered down (for example by switching off the ignition or if the fuse to the power feed is removed), the control module will attempt again to communicate when the control module is powered up again. When troubleshooting such faults, therefore, it is important to know what kind of power feed is used for the control module in question.

Configuration fault

The central electronic module (CEM) transmits at regular intervals a control message to all control modules on the CAN network, This message includes, among other things, the ID number of the signal configuration currently being used. The reason for this is that all control modules on the CAN network must have the same signal configuration if they are to be able to communicate.

If the ID number of a control module's signal configuration does not tally with the ID number transmitted by the central electronic module (CEM), a diagnostic trouble code (DTC) is stored in the control module with the faulty signal configuration.

The control module which stores the diagnostic trouble code (DTC) will stop communicating on the CAN network but will still monitor traffic and respond to diagnostics communication.

THE NETWORK

OVERVIEW

Increasing demands for further functionality in the vehicle, both statutory requirements and customers, have led to increased complexity in the vehicle.

This, in turn, has encouraged developments towards more flexible electrical systems. The CAN-net (Controller Area Network) is a result of this research. The network permits the transmission and receipt of a large number of different commands and messages on the same wiring. Earlier, every command or message required a separate cable. Using networks has allowed functionality to be expanded without increasing the number of cables.

The number of commands and messages which can be handled on the network depends on factors such as the network speed and the length of the message or command. The Volvo network which is based on a control area network (CAN), can transmit over 500 different signals and approximately 100 messages. These messages are also called frames. Each message can contain several signals, e. g., a message to Rear electronic module (REM) can contain all signals for how the tail lights should be lit.

ADVANTAGES OF A NETWORK

Easier to add further functions and install accessories.

Because the control modules in the network are already connected to each other and are easy to add more information to, all that is required is:

- to connect the sensors to the nearest control module
- to connect the controlled component to the nearest control module
- to download software to alter the configuration and programming of the network.

The length of the wiring and the number of components which are introduced with the vehicle are less than previously.

An example of this is the addition of cruise control for the car.

Before the introduction of the network the installation of control modules, switches, vacuum pumps, vacuum servos, hoses and cable harnesses was necessary.

With the network only the installation of a switch and the downloading of software which alters the configuration of the vehicle is required.

Easier to introduce logical functions.

Logical functions can be explained as "If this occurs then the following corrective action must be carried out". For example, the system is programmed so that if a tail light is broken, a message is transmitted via the control area network (CAN) to the driver information module (DIM) to warn the driver.

The only thing you need to do to introduce a logical function is alter the programming of control modules affected - the rear electronic module (REM) and the driver information module (DIM) in the example above.

Introduction of logic functions does not increase the number of components or cables.

Easy to adapt the system to customer and market requirements.

The functions can be altered depending on the requirements/demands of the customer and market. An example of this could be fog tail lamps. Certain markets use two fog tail lamps, others only use one on the driver's side. Previously it was required that different replacement parts were stored for different markets. Now the same replacement part can be used for all markets, by changing the programming depending on the market.

A similar basic system can be used for a whole model programme.

Similar networks (hardware) can be used for a large number of different vehicles.

The only thing that differentiates the vehicles is:

- the components (control modules, sensors controlled components etc.) which are connected to the system
- Which components do what.
- Which components/functions are standard /optional/accessories
- Configuration/programming of the system

TIRE PRESSURE MONITORING SYSTEM (TPMS) (2007-2012)

DESIGN

TIRE PRESSURE MONITORING SYSTEM (TPMS)

Fig. 115: Locating Tire Pressure Monitoring System (TPMS) Components
Courtesy of VOLVO CARS CORPORATION

The purpose of the tire pressure monitoring system, TPMS, is to enable the driver to have optimum tire pressure by giving a warning when the pressure in any of the tires becomes too low. Correct tire pressure is important for:

- achieving good fuel economy
- achieving optimum comfort and good driving characteristics
- preventing flat tires due to too low tire pressure.

The function is integrated in the Upper electronic module (UEM). Sensors are installed together with the air valve on each wheel to measure the air pressure in the tires.

NOTE: **The system shall be regarded as a helpful tool for the driver to maintain correct tire pressure. The system shall NOT be regarded as a warning system that some serious vehicle malfunction has occurred.**

No tire seals completely tight - there is always some minor leak since the tire can never seal tight against the rim. When inflating the tires with air, try to make sure that all tires have the same temperature as the outdoor temperature. Also, do not use so-called "Comfort pressure" as this gives a tire pressure that is too close to the limit value for the monitoring system. This means that even minor changes in temperature or load can result in tire pressure becoming too low for what the system considers acceptable.

"Comfort pressure" may also have a negative impact on the vehicle's driving characteristics. When inflating tires, inflate to the pressure indicated on the decal on the body or in the owner's manual. The pressure is developed with consideration of fuel economy, comfort, and safety. Therefore, do not use another pressure. If the decal is missing or damaged, order and install a new

one. This is especially important on vehicles with TPMS.

TIRE PRESSURE SENSOR

Fig. 116: Locating Tire Pressure Sensor
Courtesy of VOLVO CARS CORPORATION

The tire pressure sensors are installed together with the air valve on the rim. The sensor consists of a pressure sensor, a communication circuit, an acceleration sensor and a battery.

NOTE: Special procedures are required for removing the tire from the rim depending on vehicle model and tire type. This is to prevent damaging the sensor.

DIAGNOSTIC FUNCTIONS

TIRE PRESSURE MONITORING SYSTEM (TPMS)

The Upper electronic module (UEM) can store diagnostic trouble codes (DTCs) in the event of a fault on the actual receiver or on one of the sensors.

In order to perform a correct evaluation of the function, the vehicle must have traveled faster than 40 km/h (25 mph) for more than 570 seconds. This time is accumulated time, i. e. the time count stops if the vehicle travels slower than 40 km/h if, for example, you stop at traffic lights.

The count continues where it was as soon as the vehicle travels faster than 40 km/h once again.

Upper Electronic Module can store two diagnostic trouble codes per sensor. One diagnostic trouble code for lost communication and one diagnostic trouble code for low battery voltage. When a diagnostic trouble code is stored, the ID-number of the sensor to which the diagnostic trouble code applies is also stored.

When a diagnostic trouble code is stored, a message will be shown in the Driver information module.

QUICK CHECK OF TPMS

Fig. 117: Checking TPMS
Courtesy of VOLVO CARS CORPORATION

NOTE: Some car/model years require that you are more accurate when aiming the diagnostic tool at the sensor for an activation to succeed. If an activation fails, realign the diagnostic tool and perform the activation again. First after three failed activation attempts can a sensor be regarded as defective.

The system can be checked, using the diagnostic tool, by activating a read off at the same time as activating the sensors using a special tool.

The special tool is placed against the tire in the place where the sensor is installed, at the same time as you push in a button on the special tool. Then the special tool sends out a signal that activates the sensor so that it starts to transmit signals to Upper Electronic Module. The activated sensor's ID-number and tire pressure are then shown on the display in the diagnostic tool. Note the sensor's id-number and its position.

FUNCTION

TIRE PRESSURE MONITORING SYSTEM

Fig. 118: Identifying Tire Pressure Monitoring System Information Display
Courtesy of VOLVO CARS CORPORATION

The system covers the upper electronic module and the sensors in the wheels. The sensors in the wheels are activated when the vehicle exceeds 40 km/h. The sensors then start to transmit data messages approximately once per minute, which are received by the remote control receiver in the Upper electronic module. These messages contain the sensor's ID number and air pressure in the tire where the sensor is mounted.

The frequency used by sensors to transmit is the same for all sensors. Thus, the control module can receive signals also from other vehicles with the same system installed. However, the ID-number in each sensor is unique.

Sensors installed on your own vehicle can be retrieved by a statistical selection in the Upper Electronic Module. When the ignition is turned on the Upper Electronic Module starts to listen for messages from the sensors. The control module registers the ID-numbers contained in the received messages transmitted by the sensors, both from own and from other vehicles.

All ID-numbers are added in a list in the internal memory by the Upper Electronic Module. For each received ID-number, the number of times it has been received is also saved. As the quantity of received ID-numbers increases, an assessment takes place of which ID-numbers have been received most times. The four ID-numbers that have been received most often get the highest "ranking" and are then considered to belong to the own vehicle.

In this way any ID-numbers that may have been received from other vehicles with the same type of system, e. g., driving in the adjacent lane, are separated. This assessment takes approx. 5 minutes if the Upper Electronic Module is empty of data.

If the evaluation has been carried out, the sensors that are assumed to belong to the actual vehicle are stored in the control module. The information remains between each driving cycle. In this case, it is sufficient for the control module to receive a message from each sensor with corresponding ID number to complete evaluation.

In Upper Electronic Module, there are tables programmed with the recommended air pressure for this specific vehicle model. This information about air pressure in tires included in messages from sensors is compared to programmed values in Upper Electronic Module.

If the pressure reported from a sensor differs more than 22% from the recommended value, a warning message will be shown in the Driver information module.

There are two warning levels that generate different warning messages, one warning for low pressure and one warning for no pressure. A message will also be shown is a sensor should stop transmitting or should receive too low battery voltage.

To reset a warning it is easiest to stop the vehicle and fill air in the tire where the air pressure is low. In order for the warning to reset air has to be filled so that the air pressure reaches a level that corresponds to at least 95% of the recommended air pressure, and then drive the vehicle faster than 40 km/h for more than 10 minutes, accumulated time.

If the customer has come to the workshop, the warning can also be reset by filling air in the tire where the air

pressure is low and then the sensor is activated with the special tool for activating the tire pressure sensor.

When air is filled and the pressure changes, the sensor immediately sends a signal to Upper Electronic Module. If the ignition is on, the warning is reset immediately.

NOTE: Only applies to USA/CDN. A warning lamp also lights in the Driver information module at the same time as the warning message.

TYRE PRESSURE MESSAGES

Message in the Driver information module	Percentage under rec. tyre pressure	Speed for resetting	Driving time for resetting
Low tyre pressure. Check the tyres.	22 %	50 km/h	5 minutes
Extremely low tyre pressure. Tyres require air immediately.	40 %	50 km/h	5 minutes

SYSTEM OVERVIEW

CONTROL MODULE

Fig. 119: Locating Tire Pressure Monitoring System Components
Courtesy of VOLVO CARS CORPORATION

The tire pressure warning function is checked by the Upper Electronic Module. The system must give a warning to driver on the driver information module display if the air pressure in one of the tires is lower than the predetermined limit value.

TRANSMISSION

DESIGN

TRANSMISSION, GENERAL

Fig. 120: Identifying Transmission
Courtesy of VOLVO CARS CORPORATION

The automatic transmission has five forward gears and one back-up gear. The fifth gear is an overdrive which saves fuel during highway driving.

The mechanical components of the transmission are enclosed within the torque converter cover, the transmission housing and valve housing.

Gearshifts are controlled by an hydraulic operating system. Gearshifts take place without freewheeling and completely automatically in terms of load and speed.

The solenoid valves are located under the valve housing cover on the transmission, in the valve housing for the hydraulic system. These are activated by the transmission control module.

The transmission input speed sensor is electro-magnetic and acts on a toothed pulse wheel. By comparing the engine and transmission speeds, the control module can determine the amount of slippage in the torque converter.

The gear-shift position sensor has three separate functions:

- using an electrical route to inform the transmission control module of the selected gear position

- to activate the back-up light when the gear selector is in -position
- To allow engine start if the gear selector is in or -position. This signal is also transmitted to the engine's control system and is used for drive position compensation of idle.

The transmission and final drive share a common oil pan. A dipstick in the transmission is used to check the oil level in the transmission.

TORQUE CONVERTER

Fig. 121: Identifying Torque Converter
Courtesy of VOLVO CARS CORPORATION

The torque converter is between the engine and the automatic transmission.

When the engine is idling the pump effect is too weak to drive the turbine and the vehicle will not move. As the engine speed rises it successively starts to drive in a gradual way. At higher engine speeds the power transfer to the turbine can be up to 95%. The torque converter functions as an hydraulic clutch. It also amplifies the torque of the engine at lower engine speeds and therefore an automatic transmission does not require as many gears as a manual transmission.

The torque converter consists of a round metal casing which contains two impeller wheels and is filled with oil. One of the impeller wheels, the pump wheel, is fixed to the casing. Both are connected to the engine crankshaft and rotate with it. The other impeller wheel, the turbine wheel, is connected to the input shaft of the

transmission and is driven by the oil which is pumped around by the pump wheel. The rotating impeller wheels and the oil in the torque converter "slip" slightly and creates a slight loss of power, which raises fuel consumption slightly.

Thanks to a third, smaller wheel, the stator wheel, the torque converter also reinforces the engine torque at low engine speeds.

DIFFERENTIAL

Fig. 122: Differential
Courtesy of VOLVO CARS CORPORATION

The differential distributes power equally between the drive wheels, even if they are rotating at different speeds.

The differential consists of the differential housing, large and small side gears, shaft journals and thrust washers.

The differential has 6 gearwheels. The differential housing is completely sealed so that if a drive shaft is removed no dirt can penetrate and no oil can run out.

FUNCTION

TRANSMISSION, GENERAL

Fig. 123: Identifying Transmission
Courtesy of VOLVO CARS CORPORATION

The basic parameters for shifting are the accelerator pedal position and the vehicle speed.

The gear shift quality is determined by the torque control by reading off speed changes of the transmission input shaft and comparing the calculated value.

This is used to calculate the pressure setting for the clutches and brakes.

TORQUE CONVERTER

Fig. 124: Identifying Torque Converter
Courtesy of VOLVO CARS CORPORATION

The torque converter functions as an hydraulic automatic clutch. When the engine is idling the pump effect is too weak to drive the turbine and the vehicle will not move. As the engine speed rises it successively starts to drive in a gradual way. At higher engine speeds the power transfer to the turbine can be up to 95%. The torque converter functions as an hydraulic clutch.

Thanks to a third, smaller wheel, the stator wheel, the torque converter also reinforces the engine torque at low engine speeds.

The rotating impellers and the oil in the torque converter "slip" slightly and create a slight loss of power, which increases fuel consumption slightly.

DIFFERENTIAL

Fig. 125: Differential
Courtesy of VOLVO CARS CORPORATION

The differential distributes power equally between the drive wheels, even if they are rotating at different speeds.

When driving straight ahead, the ring wheel and differential housing rotate at the same speed as the drive shafts and the driving wheels.

When cornering, the differential gears rotate to compensate for the different speeds of the wheels. Because the small side gears are rotating on the shaft journal, the drive shafts can rotate at different speeds. Power is transferred from the differential housing to the drive shafts via the small side gears in the same way as when driving straight ahead. Both drive wheels still have the same driven power.

Cars with four wheel drive have a splined pin on the differential housing. The sleeve on the pin connects the differential housing with the bevel gear. This transfers the power to the rear wheels.

GEAR SELECTOR ASSEMBLY

Fig. 126: Gear Selector Assembly
Courtesy of VOLVO CARS CORPORATION

Fig. 127: Gear Selector Assembly
Courtesy of VOLVO CARS CORPORATION

The gear selector assembly is positioned in the center console and is mechanically connected to the transmission by a cable which affects the gear valve.

Gear selectors and cables are shaped differently depending on which car model they are installed in.

Gear selector assemblies with Geartronic, in addition to P/R/N/D modes, also have a manual shifting mode. The manual gear positions can be selected at any point while driving. The engaged gear is locked until the driver selects another gear. The automatic transmission only down shifts if the vehicle slows down to very low speed.

To downshift the gear selector must be moved to minus. To upshift the gear selector must be moved to plus. At start, 3rd is the highest possible gear.

The engine can only be started in position **P** or **N** .

THE DIFFERENT GEAR SELECTOR POSITIONS

Position	Meaning	Function
	Parking	The output shaft of the transmission is locked, so that the vehicle does not roll. This position should be selected when the vehicle is parked or the engine is started.

	Back-up	Back-up gear. This position must only be selected when the vehicle is stationary.
	Neutral	Neutral means that no gear is engaged and the vehicle can roll freely. The engine can be started in this position.
	Drive	The D position is used for all forward motion. When D is engaged the engine drives the vehicle forward. Up and down shifting occurs automatically depending on acceleration and speed.
	Manual	This position allows the driver to change gears manually.

POWER FLOW

When throttling off, the output shaft's power in 5th, 4th, 3rd, 2nd or reverse gear goes directly to the input shaft without any freewheel, which provides engine braking. 1st gear does not have any engine braking since the power transmission is interrupted by freewheel.

Position

Fig. 128: Identifying Power Flow Position P
Courtesy of VOLVO CARS CORPORATION

Primary shaft

The input shaft rotates clockwise. All clutches and brakes are disengaged, and no power is transferred to the planetary trains.

Output shaft

No power is transmitted to the output shaft. Brake band locks the sun gear so that it cannot rotate in any direction. Shiftlock, which is affected by the mechanical link system, is engaged with the lock wheel on the output shaft and prevents the vehicle from rolling.

Position

Fig. 129: Identifying Output Shaft Position N
Courtesy of VOLVO CARS CORPORATION

Primary shaft

The input shaft rotates clockwise. All clutches and brakes are disengaged, and no power is transferred to the planetary trains.

Output shaft

No power is transmitted to the output shaft. Brake band locks the sun gear so that it cannot rotate in any direction. Shift-lock is disengaged. The planetary gears can rotate freely around the sun gear and the vehicle will start to roll if it is on an incline.

The reason for the brake being activated in both as -position is to minimize the engagement shock that otherwise is produced when several brakes and clutches are activated at the same time when the gear selector is moved to or -position. Since is still activated in both first gear and reverse, in this way simultaneous engagements are reduced.

Position and 1st gear

Fig. 130: Identifying Output Shaft Position D And 1st Gear
Courtesy of VOLVO CARS CORPORATION

Main section

The input shaft rotates clockwise. Clutch connects the input shaft to the rear ring gear, which rotates clockwise. The rear planetary gear rotates clockwise. The front large planetary gear rotates clockwise with the rear planetary gear as a unit.

The front small planetary gear rotates clockwise. The front ring gear rotates counter-clockwise. Freewheel locks the front ring gear's rotation counter-clockwise.

The front and rear planetary carriers are turned clockwise because of the reactive forces from the small gear. The primary intermediate gear rotates clockwise with the front and rear planetary carriers as a unit.

U/D section

The secondary intermediate gear rotates counter-clockwise. The front ring gear rotates counter-clockwise with secondary intermediate gear as a unit.

The front planetary gear rotates clockwise. The front planetary gear rotates clockwise. The rear sun gear rotates clockwise with the front sun gear as a unit.

The rear planetary gear rotates counter-clockwise. Brake locks the rear planetary carrier's rotation. The rear ring gear rotates counter-clockwise. The front planetary carrier and final drive pinion rotates counter-clockwise with the rear ring gear as a unit. The final drive rotates clockwise.

Engine brake

The primary intermediate gear and front and rear main planetary carriers rotate clockwise. The rear planetary carrier rotates clockwise. The rear planetary gear is turned counter-clockwise while it rotates counter-clockwise because of the resistance from the rear ring gear.

The front large gear wheel is turned clockwise while it rotates counter-clockwise and the small gear wheel is turned clockwise while it rotates clockwise. The front planetary carrier is turned clockwise.

The front ring gear rotates clockwise because the front small gear rotates clockwise, but drive force is reduced because freewheel is disengaged. Therefore the engine brake does not operate.

Position and 2nd gear

Fig. 131: Engine Brake Position D And 2nd Gear
Courtesy of VOLVO CARS CORPORATION

Main section

The input shaft rotates clockwise. Clutch connects the input shaft to the rear ring gear. The rear ring gear rotates clockwise. The rear planetary gear rotates clockwise.

The front large planetary gear rotates clockwise with the rear planetary gear as a unit. Brake, freewheel and brake lock the sun gear's rotation.

The front and rear planetary carriers are turned clockwise because of the reactive forces from the front large gear. The primary intermediate gear rotates clockwise with the front and rear planetary carriers as a unit.

U/D section

The secondary intermediate gear rotates counter-clockwise. The front ring gear rotates counter-clockwise with the secondary intermediate gear as a unit. The front planetary gear rotates clockwise. The front planetary gear rotates clockwise.

The rear sun gear rotates clockwise with the front sun gear as a unit. The rear planetary gear rotates counter-clockwise. Brake locks the rear planetary carrier's rotation. The rear ring gear rotates counter-clockwise.

The front planetary carrier and final drive pinion rotates clockwise with the rear ring gear as a unit. The final drive rotates clockwise.

Engine brake

Drive force is transferred directly to the input shaft without the one way clutch. Therefore the engine brake operates.

Position and 3rd gear

Fig. 132: Engine Brake Position D And 3rd Gear
Courtesy of VOLVO CARS CORPORATION

Main section

The input shaft rotates clockwise. Clutch connects the input shaft to the rear ring gear. The rear ring gear rotates clockwise. The rear planetary gear rotates clockwise.

The front large planetary gear rotates clockwise with the rear planetary gear as a unit. Brake, freewheel and brake lock the sun gear's rotation.

The front and rear planetary carriers are turned clockwise because of the reactive forces from the front large gear. The primary intermediate gear rotates clockwise with the front and rear planetary carriers as a unit.

U/D section

The secondary intermediate gear rotates counter-clockwise. The front ring gear rotates counter-clockwise with the secondary intermediate gear as a unit. The front planetary gear rotates clockwise. Brake locks the rotation of the front and rear sun gear.

The front planetary carrier is turned clockwise because of the reactive forces from the front large planetary gear. The front planetary carrier and final drive pinion rotate clockwise with the rear ring gear as a unit. The final drive rotates clockwise.

Engine brake

Drive force is transferred directly to the input shaft without the one way clutch. Therefore the engine brake operates

Position and 4th gear

Fig. 133: Engine Brake Position D And 4th Gear
Courtesy of VOLVO CARS CORPORATION

Main section

The input shaft rotates clockwise. Clutch connects the input shaft to the rear ring gear. The rear ring gear rotates

clockwise. The rear planetary gear rotates clockwise.

The front large planetary gear rotates clockwise with the rear planetary gear as a unit. Brake, freewheel and brake lock the sun gear's rotation.

The front and rear planetary carriers are turned clockwise because of the reactive forces from the front large gear. The primary intermediate gear rotates clockwise with the front and rear planetary carriers as a unit.

U/D section

The secondary intermediate gear rotates clockwise. The front ring gear rotates counter-clockwise with the secondary intermediate gear as a unit. Clutch C3 connects the sun gear to the front planetary carrier.

The front planetary gear cannot rotate and the U/D unit rotates counter-clockwise as a unit. The final drive pinion rotates counter-clockwise with the U/D unit as a unit. The final drive rotates clockwise.

Engine brake

Drive force is transferred directly to the input shaft without the one way clutch. Therefore the engine brake operates.

Position and 5th gear

Courtesy of VOLVO CARS CORPORATION

Main section

The input shaft rotates clockwise. Clutch connects the input shaft to the sun gear. The sun gear rotates clockwise.

The rear planetary gear rotates counter-clockwise. The front large planetary gear rotates counter-clockwise with the rear planetary gear as a unit. The front small planetary gear rotates clockwise.

Brake locks the front ring gear's rotation counter-clockwise. The front and rear planetary carriers are turned clockwise because of the reaction forces from the front small gear. The primary intermediate gear rotates counter-clockwise with the front and rear planetary carriers as a unit.

U/D section

The secondary intermediate gear rotates clockwise. The front ring gear rotates clockwise with the secondary intermediate gear as a unit. The front planetary gear rotates clockwise. The front sun gear rotates counter-clockwise.

The rear sun gear rotates counter-clockwise with the front sun gear as a unit. The rear planetary gear rotates clockwise. Brake locks the rear planetary carrier's rotation. The rear ring gear rotates clockwise. The front

planetary carrier and final drive pinion rotate clockwise with the rear ring gear as a unit. The final drive rotates counter-clockwise.

Engine brake

Drive force is transferred directly to the input shaft without the one way clutch. Therefore the engine brake operates.

TOWING

Towing is only permitted in the vehicle's forward direction at max. 80 km/h for max. 80 km.

The gear selector shall be in position.

CAUTION: The car must not be towed backwards under any circumstances.

OVERVIEW

Fig. 136: Identifying Transmission
Courtesy of VOLVO CARS CORPORATION

AW55-51 is a 5 speed electronically controlled automatic transmission with a lock-up function for the three

highest gears. The transmission control module (TCM) adapts the gear changes to ensure that the correct gear is selected for the driving mode, engine load, driver requirements, speed etc. This gives good fuel economy combined with increased comfort by ensuring smoother gear changes and lower noise levels.

In a vehicle with an automatic transmission, the driver neither needs to decide which gear should be used nor shift gear. There is a operating system in the AW55-51 which uses a torque converter and gear shift system to do this.

TRANSMISSION (TF-80SC; 2007-2012)

DESIGN AND FUNCTION

TRANSMISSION COMPONENTS

Fig. 137: Identifying Cross-Section Of Transmission
Courtesy of VOLVO CARS CORPORATION

Number	Designation	Number	Designation
1	Clutch C2	8	Torque converter
2	Brake B2	9	Differential unit
3	Freewheel F1	10	Driven counter rotating gear
4	Front planetary train	11	Driven gear
			Rear planetary train,

5	Clutch C1	12	Ravigneaux
6	Brake B1	13	Input shaft
7	Clutch C3		

TORQUE CONVERTER WITH LOCK-UP

Fig. 138: Identifying Cross Section Of Torque Converter With Lock-Up
Courtesy of VOLVO CARS CORPORATION

Number	Designation	Number	Designation
1	Lock-up-clutch	5	Stator
2	Casing	6	Oil pump
3	Turbine rotor	7	Input shaft
4	Pump rotor		

The torque converter is between the engine and the automatic transmission. It consists of a round metal casing which contains three impellers. The torque converter is filled with oil. The first impeller, pump rotor, is secured in the torque converter casing, which is connected to the engine's crankshaft via a carrier plate. The pump rotor rotates with the crankshaft.

The second impeller, the turbine rotor, is connected to the transmission's input shaft and is driven by the oil that is circulated by the pump rotor.

The third impeller, the stator, is located between the pump rotor and the turbine rotor.

There is a hydraulically controlled lock-up clutch with a friction plate in the torque converter. The turbine rotor can connect with the torque converter housing via the lock-up clutch. This reduces fuel consumption.

The torque converter functions like a hydraulic automatic clutch. At idle, the pump action is too weak to drive the turbine rotor and thus the vehicle is stationary. When the engine speed is increased the turbine rotor starts to drive in a smooth way. Thanks to the stator rotor, the torque converter can also reinforce the engine's torque when starting and low driving speed.

The rotating impellers and the oil in the torque converter "slip" slightly. This gives a certain power loss, which slightly increases fuel consumption.

When the vehicle is moving the torque converter's reinforcement of the engine's torque is not needed. In this situation the lock-up function is activated and, at a certain speed, mechanically connects the transmission's input shaft with the engine. This is automatic and cannot be affected by the driver. The engine speed drops and, since the torque converter's slipping disappears, fuel consumption is also reduced.

PLANETARY TRAIN

Fig. 139: Identifying Planetary Train
Courtesy of VOLVO CARS CORPORATION

X = locked

Number	Designation	Number	Designation
1	Rear planetary train, (Ravigneaux)	6	Input shaft
2	Front planetary train	7	Driven gear
3	Planetary gear	8	Oil pump
4	Sun gear	9	Differential
5	Ring gear	10	Driven counter rotating gear

Unique to the TF-80SC is a Ravigneaux planetary gear connected in series to a conventional planetary gear. The conventional planetary gear creates a reduction in RPM in the Ravigneaux planetary gear for 1st gear up to 5th gear and reverse.

The planetary gear's ratios are controlled by 3 clutches (C1, C2, C3) and 2 brakes (B1, B2).

The number of planetary gears depends on the engine's cylinder displacement and can therefore differ from what is shown here.

Planetary train, Ravigneaux

Fig. 140: Identifying Ravigneaux Planetary Train
Courtesy of VOLVO CARS CORPORATION

Number	Designation	Number	Designation
1	Large sun gear	4	Inner planetary gear
2	Small sun gear	5	Ring gear
3	Outer planetary gear	6	Planetary wheel carrier

The characteristic of a Ravigneaux planetary train is that several gears can be used in comparison to a conventional planetary train. It is compact (takes up little room) in relation to the number of possible ratios. The Ravigneaux planetary train has two sun gears of different diameters and sets of two planetary gears, an inner

and outer set. The inner planetary gears are constantly connected to the outer planetary gears and the small sun gear. The outer planetary gears are constantly connected to the ring gear and large sun gear.

The planetary train has a common planetary gear carrier for both sets of planetary gears.

Principles of function

Fig. 141: Identifying Cross-Section Of Ravigneaux Planetary Train
Courtesy of VOLVO CARS CORPORATION

Number	Designation	Number	Designation
1	Small sun gear	4	Outer planetary gear
2	Large sun gear	5	Ring gear
3	Inner planetary gear	6	Planetary wheel carrier

The ratios are obtained through different combinations of locked and/or connected components. The table displays the principle for how the ratios are obtained from large ratio, 1, to small ratio, 6, and counter rotation (i. e. reverse with large ratio).

Combination	Power in	Locked	Power out
1	Small sun gear	Planetary gear carrier	Ring gear
2	Small sun gear	Large sun gear	Ring gear

3	Small sun gear and large sun gear	No component	Ring gear
4	Small sun gear and planetary gear carrier	No component	Ring gear
5	Large sun gear and planetary gear carrier	No component	Ring gear
6	Planetary gear carrier	Large sun gear	Ring gear
Reverse	Large sun gear	Planetary gear carrier	Ring gear

OIL PUMP

Fig. 142: Identifying Oil Pump
Courtesy of VOLVO CARS CORPORATION

The oil pump is of "non-crescent" type and is located after the torque converter. It is driven by the engine's crankshaft via the torque converter housing.

The oil pump supplies the hydraulics with oil and supplies the other components of the transmission with oil for lubrication and cooling. Excess oil is routed back to the oil sump.

OIL COOLER

The oil is routed in/out in separate lines to the external oil cooler.

THE HYDRAULIC SYSTEM

Fig. 143: Identifying Hydraulic System
Courtesy of VOLVO CARS CORPORATION

Number	Designation	Number	Designation
1	Transmission control module (TCM)	5	Oil cooler
2	Torque converter	6	Oil pump
3	Valves and solenoids	7	Planetary train
4	Clutches and brakes	8	Oil sump

The transmission's hydraulic system consists of oil pump, torque converter, hydraulic control system and oil cooler.

The solenoids, which control the hydraulic valves, are located in the transmission's control system, which are mounted on the front edge of the transmission. The solenoids are activated by the Transmission control module (TCM).

The oil pump supplies the hydraulics with oil and supplies the other components of the transmission with oil for lubrication and cooling. Excess oil is routed back to the oil sump.

CAUTION: The transmission oil differs from conventional ATF oil properties. Always use transmission oil that is specified for this transmission. Otherwise the

function of the transmission will be damaged.

The oil level is checked though a level pipe (transmission does not have conventional oil dipstick).

Fig. 144: Identifying Transmission Control Module (TCM), Solenoids And Sensors
Courtesy of VOLVO CARS CORPORATION

S1 = Solenoid, S1	SLU = Lock-up solenoid, SLU
S2 = Solenoid, S2	C1 = Clutch, C1
SLC1 = Line pressure solenoid, SLC1	C2 = Clutch, C2
SLC2 = Line pressure solenoid, SLC2	C3 = Clutch, C3
SLC3 = Line pressure solenoid, SLC3	B1 = Brake, B1
SLB1 = Line pressure solenoid, SLB1	B2 = Brake, B2
SLT = Line pressure solenoid, SLT	LU = Lock-up

Shifting occurs by the oil pump building up hydraulic pressure. The hydraulic valves, which are controlled by their respective solenoids, send the hydraulic pressure to the relevant clutch, brake or lock-up depending on which signals come from the Transmission control module (TCM).

Hydraulic pressure chamber

Fig. 145: Identifying Hydraulic Pressure Chambers
Courtesy of VOLVO CARS CORPORATION

A = Piston's hydraulic pressure chamber

B = Counter acting hydraulic pressure chamber

When the rotation of the clutch increases, the centrifugal force affects the oil inside the clutch. The hydraulic pressure increases and the clutch engages. The centrifugal force means that a difference occurs in the rotation between the input and output shafts, which can mean a shift judder. To solve this, there is an extra pressure chamber opposite the piston's hydraulic pressure chamber. This extra pressure chamber means that the centrifugal force also works in the opposite direction and therefore affects the pressure from the piston's hydraulic pressure chamber. In addition, the clutch does not engage too soon.

GEAR SELECTOR ASSEMBLY

Fig. 146: Identifying Gear Selector Assembly
Courtesy of VOLVO CARS CORPORATION

The gear selector assembly is in the tunnel console. It is mechanically connected to the transmission by a cable which moves the gear valve. The gear valve is integrated in the Transmission control module (TCM). The gear selected is indicated by a row of LEDs in the top panel on the gear selector assembly.

Gear selector assemblies with Geartronic, in addition to P/R/N/D modes, have a manual (M) shifting mode. The manual gear positions can be selected at any point while driving. The engaged gear is locked until the driver selects another gear. The automatic transmission only down shifts if the vehicle slows down to very low speed. To downshift the gear selector must be moved to minus (-). To upshift the gear selector must be moved to plus (+). At start, 3rd is the highest possible gear.

The engine can only be started in position P or N.

THE DIFFERENT GEAR SELECTOR POSITIONS:

Position	Meaning	Function
P	Park	The transmission's output shaft is locked, so that the vehicle does not roll. This position should be selected when the engine is started or the vehicle is parked.
R	Reverse	Reverse gear. This mode may only be engaged when the vehicle is completely

		stationary.
N	Neutral	Neutral means that no gear is engaged. The engine can start and run freely.
D	Drive	When D is engaged, the engine drives the vehicle forward except when idling. The D position is used for all forward motion. Up and down shifting occurs automatically depending on acceleration and speed.
M	Manual	This position allows the driver to change gears manually.

POWER FLOW

Clutches, brakes and freewheel

Fig. 147: Identifying Clutches, Brakes And Freewheel
Courtesy of VOLVO CARS CORPORATION

Clutch/Brakes	Function
Clutch C1	Connects the front planetary gear carrier with the rear planetary train's small sun gear.
Clutch C2	Connects the input shaft with the rear planetary gear carrier.
Clutch C3	Connects the front planetary gear carrier with the rear planetary train's large sun gear.

Brake B1	Locks the rear planetary train's large sun gear.
Brake B2	Locks the rear planetary train's planetary gear carrier.
Freewheel F1	Locks the rear planetary gear carrier so that it does not go counter-clockwise.

Position D, 1st gear

Fig. 148: Identifying Position D For 1st Gear
Courtesy of VOLVO CARS CORPORATION

Planetary train unit	Power in	Locked	Power out
Front	Ring gear	Sun gear	Planetary gear carrier
Rear	Small sun gear	Planetary gear carrier	Ring gear

The input shaft rotates clockwise, the same direction as the torque converter's turbine rotor.

The front planetary train's ring gear rotates clockwise.

The front planetary train's planetary gear rotates clockwise on its shafts. Because the front planetary train's sun gear is locked by the oil pump, the planetary train's planetary gear presses against the front planetary train's ring gear, and therefore rotates around the sun gear. Because the front planetary train's ring gear has inner teeth, the direction of rotation does not change.

The front planetary gear carrier rotates clockwise.

Clutch C1 rotates clockwise and connects the front planetary gear carrier with the rear planetary train's small sun gear.

Rear planetary train's sun gear rotates clockwise.

The rear planetary train's inner planetary gear rotates counter-clockwise on its shaft. The rear planetary gear carrier attempts to rotate counter-clockwise but is prevented by freewheel F1.

The rear planetary train's outer planetary gear rotates clockwise on its shafts. The rear planetary train's small sun gear rotates counter-clockwise, at idle.

The rear planetary train's ring gear rotates clockwise using the rear planetary train's outer planetary gear. Because the rear planetary train's ring gear has inner teeth, the direction of rotation does not change.

The driven gear rotates clockwise. Because the rear planetary train's ring gear is on the driven gear, the driven gear rotates in the same direction as the rear planetary train's ring gear.

The counter-rotating gear rotates counter-clockwise.

The differential's ring gear rotates clockwise.

Position D, 2nd gear

Fig. 149: Identifying Position D For 2nd Gear

Planetary train unit	Power in	Locked	Power out
Front	Ring gear	Sun gear	Planetary gear carrier
Rear	Small sun gear	Large sun gear	Ring gear

The input shaft rotates clockwise, the same direction as the torque converter's turbine rotor.

The front planetary train's ring gear rotates clockwise.

The front planetary train's planetary gear rotates clockwise on its shafts. Because the front planetary train's sun gear is locked by the oil pump, the planetary train's planetary gear presses against the front planetary train's ring gear, and therefore rotates around the sun gear. Because the front planetary train's ring gear has inner teeth, the

direction of rotation does not change.

The front planetary gear carrier rotates clockwise.

Clutch C1 rotates clockwise and connects the front planetary gear carrier with the rear planetary train's small sun gear.

Rear planetary train's sun gear rotates clockwise.

The rear planetary train's large sun gear is locked by brake B1.

The rear planetary train's inner planetary gear rotates counter-clockwise on its shaft.

The rear planetary train's outer planetary gear rotates clockwise on its shafts.

The rear planetary train's ring gear rotates clockwise using the rear planetary train's outer planetary gear. Because the rear planetary train's ring gear has inner teeth, the direction of rotation does not change.

The driven gear rotates clockwise. Because the rear planetary train's ring gear is on the driven gear, the driven gear rotates in the same direction as the rear planetary train's ring gear.

The counter-rotating gear rotates counter-clockwise.

The differential's ring gear rotates clockwise.

Engine brake

When the engine brake works, the driven force is transferred from the tires.

Position D, 3rd gear

Fig. 150: Identifying Position D For 3rd Gear
Courtesy of VOLVO CARS CORPORATION

Solenoid						Clutch			Brakes		Freewheel
SLC1	SLC 2	SLC 3	SLB1	S1	S2	C1	C2	C3	B1	B2	F1
-	X	-	X	-	-	X	-	X	-	-	-

X = activated

- = not activated

Planetary train unit	Power in	Locked	Power out
Front	Ring gear	Sun gear	Planetary gear carrier
Rear	Small sun gear and large sun gear	No component	Ring gear

The input shaft rotates clockwise, the same direction as the torque converter's turbine rotor.

The front planetary train's ring gear rotates clockwise.

The front planetary train's planetary gear rotates clockwise on its shafts. Because the front planetary train's sun gear is locked by the oil pump, the planetary train's planetary gear presses against the front planetary train's ring

gear, and therefore rotates around the sun gear. Because the front planetary train's ring gear has inner teeth, the direction of rotation does not change.

The front planetary gear carrier rotates clockwise.

Clutch C1 rotates clockwise and connects the front planetary gear carrier with the rear planetary train's small sun gear.

Clutch C3 rotates clockwise and connects the front planetary gear carrier with the rear planetary train's large sun gear.

The rear planetary train rotates clockwise. Because the rear planetary train's inner and outer planetary gears are in constant engagement with each other, they are kinetically locked in relation to each other. The kinetic energy from both the rear planetary train's sun gears is therefore transferred to the rear planetary train's ring gear.

The rear planetary train's ring gear rotates clockwise.

The driven gear rotates clockwise. Because the rear planetary train's ring gear is on the driven gear, the driven gear rotates in the same direction as the rear planetary train's ring gear.

The counter-rotating gear rotates counter-clockwise.

The differential's ring gear rotates clockwise.

Engine brake

When the engine brake works, the driven force is transferred from the tires.

Position D, 4th gear

Fig. 151: Identifying Position D For 4th Gear
Courtesy of VOLVO CARS CORPORATION

Solenoid						Clutch			Brakes		Freewheel
SLC1	SLC 2	SLC 3	SLB1	S1	S2	C1	C2	C3	B1	B2	F1
-	-	X	X	-	-	X	X	-	-	-	-

X = activated

- = not activated

Planetary train unit	Power in	Locked	Power out
Front	Ring gear	Sun gear	Planetary gear carrier
Rear	Small sun gear and planetary gear carrier	No component	Ring gear

The input shaft rotates clockwise, the same direction as the torque converter's turbine rotor.

The front planetary train's ring gear rotates clockwise.

The front planetary train's planetary gear rotates clockwise on its shafts. Because the front planetary train's sun gear is locked by the oil pump, the planetary train's planetary gear presses against the front planetary train's ring

gear, and therefore rotates around the sun gear. Because the front planetary train's ring gear has inner teeth, the direction of rotation does not change.

The front planetary gear carrier rotates clockwise.

Clutch C1 rotates clockwise and connects the front planetary gear carrier with the rear planetary train's small sun gear.

The intermediate shaft rotates clockwise, the same direction as the input shaft.

Clutch C2 rotates clockwise.

The rear planetary gear carrier rotates clockwise.

The rear planetary train's inner planetary gear rotates clockwise on its shafts.

The rear planetary train's outer planetary gear rotates counter-clockwise on its shafts.

The rear planetary train's ring gear rotates clockwise. Because the rear planetary train's outer planetary gear rotation pulls away from the rear planetary gear carrier's rotation, the ring gear's speed is lower than the speed at the planetary carrier.

The driven gear rotates clockwise. Because the rear planetary train's ring gear is on the driven gear, the driven gear rotates in the same direction as the rear planetary train's ring gear.

The counter-rotating gear rotates counter-clockwise.

The differential's ring gear rotates clockwise.

Engine brake

When the engine brake works, the driven force is transferred from the tires.

Position D, 5th gear

Fig. 152: Identifying Position D For 5th Gear
Courtesy of VOLVO CARS CORPORATION

Solenoid						Clutch			Brakes		Freewheel
SLC1	SLC 2	SLC 3	SLB1	S1	S2	C1	C2	C3	B1	B2	F1
X	-	-	X	-	-	-	X	X	-	-	-

X = activated

- = not activated

Planetary train unit	Power in	Locked	Power out
Front	Ring gear	Sun gear	Planetary gear carrier
Rear	Large sun gear and planetary gear carrier	No component	Ring gear

The input shaft rotates clockwise, the same direction as the torque converter's turbine rotor.

The front planetary train's ring gear rotates clockwise.

The front planetary train's planetary gear rotates clockwise on its shafts. Because the front planetary train's sun gear is locked by the oil pump, the planetary train's planetary gear presses against the front planetary train's ring

gear, and therefore rotates around the sun gear. Because the front planetary train's ring gear has inner teeth, the direction of rotation does not change.

The front planetary gear carrier rotates clockwise.

Clutch C3 rotates clockwise and connects the front planetary gear carrier with the rear planetary train's large sun gear.

The rear planetary train's large sun gear rotated clockwise. Its speed is reduced by the front planetary train so that the speed becomes lower than the speed of the input shaft.

The intermediate shaft rotates clockwise, the same direction as the input shaft.

Clutch C2 rotates clockwise.

The rear planetary gear carrier rotates clockwise.

The rear planetary train's outer planetary gear rotates clockwise. Because the rear planetary gear carrier rotates faster than the rear planetary train's large sun gear, the inner planetary gears are pressed outwards by the speed difference and rotate clockwise on their shafts.

The rear planetary train's ring gear rotates clockwise. Because the rear planetary train's outer planetary gear rotation is added to the rear planetary gear carrier's rotation, the ring gear's speed is greater than the speed at the planetary carrier.

The driven gear rotates clockwise. Because the rear planetary train's ring gear is on the driven gear, the driven gear rotates in the same direction as the rear planetary train's ring gear.

The counter-rotating gear rotates counter-clockwise.

The differential's ring gear rotates clockwise.

Engine brake

When the engine brake works, the driven force is transferred from the tires.

Position D, 6th gear

Fig. 153: Identifying Position D For 6th Gear
Courtesy of VOLVO CARS CORPORATION

Solenoid						Clutch			Brakes		Freewheel

Planetary train unit	Power in	Locked	Power out
Front	Ring gear	Sun gear	Planetary gear carrier
Rear	Large sun gear	Planetary gear carrier	Ring gear

The input shaft rotates clockwise, the same direction as the torque converter's turbine rotor.

The front planetary train's ring gear rotates clockwise.

The front planetary train's planetary gear rotates clockwise on its shafts. Because the front planetary train's sun gear is locked by the oil pump, the planetary train's planetary gear presses against the front planetary train's ring gear, and therefore rotates around the sun gear. Because the front planetary train's ring gear has inner teeth, the direction of rotation does not change.

The front planetary gear carrier rotates clockwise.

Clutch C3 rotates clockwise and connects the front planetary gear carrier with the rear planetary train's large sun gear.

The rear planetary train's large sun gear rotates clockwise.

Brake B2 locks the rear planetary gear carrier.

The rear planetary train's outer planetary gear rotates counter-clockwise.

The rear planetary train's ring gear rotates counter-clockwise using the rear planetary train's outer planetary gear. Because the rear planetary train's ring gear has inner teeth, the direction of rotation does not change.

The driven gear rotates counter-clockwise. Because the rear planetary train's ring gear is on the driven gear, the driven gear rotates in the same direction as the rear planetary train's ring gear.

The counter-rotating gear rotates clockwise.

The differential's ring gear rotates counter-clockwise.

Engine brake

When the engine brake works, the driven force is transferred from the tires.

DIFFERENTIAL

Fig. 155: Identifying Differential
Courtesy of VOLVO CARS CORPORATION

The differential consists of the differential housing, large and small differential gears, shaft journals and thrust washers. The differential housing is completely sealed so that if a drive shaft is removed no dirt can penetrate and no oil can run out.

The differential distributes power equally between the drive wheels, even if they are rotating at different speeds. When driving straight ahead, the ring gear and differential housing rotate at the same speed as the drive shafts and the driving wheels. When cornering, the differential gears rotate to compensate for the different speeds of the wheels. Because the small differential gears are rotating on the shaft journal, the drive shafts can rotate at different speeds. Power is transferred from the differential housing to the drive shafts via the small differential gears in the same way as when driving straight ahead. Both drive wheels still have the same driven power.

AWD

Cars with four wheel drive have a splined pin on the differential housing. The sleeve on the pin connects the differential housing with the bevel gear. This transfers the power to the rear wheels.

OVERVIEW

Fig. 158: Identifying Transmission
Courtesy of VOLVO CARS CORPORATION

HINT: The shape of the transmission casing differs depending on which engine is included in the driveline.

TF-80SC (TF-80SC AWD) is an electronically controlled 6-speed automatic transmission with Geartronic.

The Geartronic function combines two transmissions in one. One adaptive 6-gear automatic transmission which enables relaxed driving, and a "manually" shifted transmission which enables more active driving with manual shifting. In case of manual shifting, the gear selector is pushed forward to upshift to a higher gear and it's pulled back to downshift to a lower gear. However, in certain situations the Transmission control module (TCM) assumes the gearshifting decisions.

TF-80SC has a lock-up-function on all forward gears except 1st gear. The torque converter has a locked and slipping lock-up-function.

Gearshifts are controlled by an hydraulic operating system. Gearshifts take place without freewheeling and completely automatically in terms of load and speed.

TF-80SC has two planetary train units, a front and a rear, whose shifts are controlled by a number of clutches and brakes. The rear planetary train is of the Ravigneaux type.

The oil level is checked by level pipe (the transmission does not have a conventional dipstick).

The transmission has a total of 8 solenoids that control the hydraulic flow. 6 of these solenoids control the shift process, 1 solenoid controls the torque converter's lock-up function and 1 solenoid controls the system pressure.

The gear selector sensor is integrated in the Transmission control module (TCM). The Transmission control module (TCM) is integrated in the transmission.

TRANSMISSION (TF-80SC AWD; 2005-2012)

DESIGN AND FUNCTION

see **DESIGN AND FUNCTION**

OVERVIEW

see **OVERVIEW**

TRANSMISSION CONTROL MODULE (TCM) (4T65 AWD; 2003-2006)

DESIGN

CONTROL MODULE

Fig. 159: Identifying Transmission Control Module
Courtesy of VOLVO CARS CORPORATION

The transmission control module (TCM) is positioned in an air cooled plastic box in the engine compartment together with the engine control module (ECM).

SHIFT SOLENOID S1 AND S2

Fig. 160: Identifying Shift Solenoid S1 And S2
Courtesy of VOLVO CARS CORPORATION

The shift solenoids S1 and S2 are positioned in the valve housing, which is mounted behind the side cover of the transmission. The shift solenoids (on/off type), consist of an electrical coil which controls a hydraulic valve. The solenoids are supplied with 12 V via the transmission control module (TCM) and grounded at the ground terminal. The shift solenoids control shifting and the transmission control module (TCM) determines which gear is to be used by activating them in different patterns.

There is a diagnostic for the electrical function of the shift solenoids. There is also a diagnostic for the hydraulic circuit, but not for the hydraulic function of the solenoids.

LOCK-UP SOLENOID, SL

Fig. 161: Identifying Lock-Up Solenoid, SL
Courtesy of VOLVO CARS CORPORATION

Lock-up solenoid SL is positioned in the valve housing, which is mounted behind the side cover on the transmission. The lock-up solenoid consists of an electrical coil which controls a hydraulic valve. The solenoid is controlled by pulse width modulation (PWM) voltage and is grounded at the ground terminal. The solenoid controls lock-up engagement of the torque converter. Engagement occurs through solenoid pulsing which provides a smooth lock-up engagement function. Power transmission then changes to mechanical power transmission through the torque converter. The hydraulic function of the solenoid is linear.

There is a diagnostic for the electrical function of the solenoid, but not for the hydraulic function.

PRESSURE SENSOR LOCK-UP

Fig. 162: Pressure Sensor Lock-Up
Courtesy of VOLVO CARS CORPORATION

The lock-up pressure sensor is positioned in the valve housing, which is mounted behind the side cover for the transmission. The lock-up pressure sensor consists of six electrical pressure switches. The pressure switches indicate the hydraulic pressure in the different transmission systems. The pressure sensor provides the transmission control module (TCM) with information about the system pressure and selected gear. The transmission control module (TCM) uses this information to control the lock-up solenoid, SL.

There are diagnostics for the lock-up pressure sensor.

LINE PRESSURE SOLENOID, STH

Fig. 163: Identifying Line Pressure Solenoid, STH
Courtesy of VOLVO CARS CORPORATION

The line pressure solenoid, STH, is positioned in the valve housing, which is behind the side cover for the transmission. The line pressure solenoid consists of an electrical coil which controls a hydraulic valve. The solenoid is controlled by pulse width modulation (PWM) voltage and is grounded via the transmission control module (TCM). The function of the solenoid is linear. The hydraulic valve is controlled by the varied current which is the result of the pulse conditions. During high pulse conditions, (at high current (approximately 1A)) the line pressure is low. During low pulse conditions (at low currents) the line pressure is high. In the event of an open-circuit, the line pressure reaches maximum which will result in harsh gear shifting. This can also result in a whining noise from the transmission pump. The hydraulic valve is then completely open.

There are diagnostics for the solenoid. There is a diagnostic for the electrical function of the solenoid. There is also a diagnostic for the hydraulic circuit, but not for the hydraulic function of the solenoid. The hydraulic tests can be carried out using a mechanical pressure gauge. The idle and stop pressure can be checked.

TRANSMISSION INPUT SPEED SENSOR (SPEED OF THE INPUT SHAFT)

Fig. 164: Identifying Transmission Speed Sensor
Courtesy of VOLVO CARS CORPORATION

The transmission input speed sensor, (input shaft speed) is positioned in the transmission housing. The sensor is an active sensor and is supplied with 12 V. When the driven gearwheel rotates, the sensor generates a pulsed current (quadratic wave) where the strength of the current depends on the position of the pulse wheel. The signals from the coil in the sensor are then effected by a magnetic resistance element, which generates a current which oscillates between 7 mA and 14 mA, and the frequency of which increase with speed. The transmission control module (TCM) calculates the transmission input speed using the signal from the sensor.

The input speed is compared with the transmission output speed from the transmission speed sensor signal to calculate the gear ratio.

There are diagnostics for the transmission input speed sensor.

TRANSMISSION OUTPUT SPEED SENSOR (SPEED OF THE OUTPUT SHAFT)

Fig. 165: Identifying Transmission Speed Sensor
Courtesy of VOLVO CARS CORPORATION

The transmission output shaft speed sensor is positioned on the transmission housing. The sensor is electro-magnetic and acts on a toothed pulse wheel. The sensor provides signals to the transmission control module (TCM) about the vehicle speed. The transmission speed sensor is an active sensor and is supplied with 12 V. When the pulse wheel rotates, the sensor generates a pulsed current (quadratic wave) where the strength of the current depends on the position of the pulse wheel. The signals from the coil in the sensor are then effected by a magnetic resistance element, which generates a current which oscillates between 7 mA and 14 mA, and the frequency of which increase with speed. The control module calculates the transmission output speed using the signals from the sensor. The signal is compared with the signal from the transmission input speed sensor and is used to calculate the gear ratio as well as for diagnostics.

There are diagnostics for the transmission output speed sensor.

TEMPERATURE SENSOR

Fig. 166: Identifying Temperature Sensor
Courtesy of VOLVO CARS CORPORATION

The temperature sensor is the NTC resistive type. The temperature sensor is positioned on the valve housing inside the side cover and measures the transmission fluid temperature in the oil pan. The temperature sensor is supplied with 5 V and is grounded via the transmission control module (TCM). The control module can determine the transmission fluid temperature by measuring the voltage drop across the NTC resistor of the sensor. The control module stores the time the temperature has been within a certain temperature range. If a certain temperature and time has been exceeded, a diagnostic trouble code (DTC) indicating that a oil change is necessary is stored.

There are diagnostics for the temperature sensor.

GEAR-SHIFT POSITION SENSOR

Fig. 167: Gear-Shift Position Sensor
Courtesy of VOLVO CARS CORPORATION

The gear-shift position sensor is located inside the transmission housing. It contains a Park / Neutral position (PNP) switch and switches which inform the transmission control module (TCM) about which gear is selected and whether back-up (reverse) gear is selected so that the reversing lamps are lit. The gear-shift position sensor is a position switch which is grounded via the chassis. The combination of pins A, B, C and PA indicate the current gear selector position (see the table below). The trailing contacts can either be closed or open. The gear-shift position sensor is not available as a replacement part.

There are diagnostics for the gear-shift position sensor.

Table for the gear-shift position sensor

The value indicates the position of the gear-shift position sensor (A, B, C and PA), see the table.

• = High signal (open)

- = Low signal (grounded)

GEAR SELECTOR MODULE (GSM)

Fig. 169: Gear Selector Module (GSM)
Courtesy of VOLVO CARS CORPORATION

The gear selector assembly is positioned in the center console and is mechanically connected to the transmission by a cable which moves the gear valve in the valve housing. The gear selector module (GSM) is positioned on the top panel of the gear selector assembly.

The gear selector module (GSM) receives gear position signals from the transmission control module (TCM) via serial communication. The transmission control module (TCM) receives the present gear position from the gear-shift position sensor. The LEDs in the top panel indicate the selected gear to the driver. The gear selector module (GSM) communicates serially with the central electronic module (CEM). The central electronic module (CEM) sends a signal to the gear selector module (GSM) to activate the shift-lock. The power supply and ground for the shift-lock solenoid are directly connected to the gear selector module (GSM).

The "W" switch in the gear selector assembly top panel is positioned on the printed circuit board for the gear selector module (GSM) and activates Winter mode. The gear selector module (GSM) checks the back-up (reverse) inhibitor function based on the vehicle speed signal from the transmission control module (TCM).

There are diagnostics for the gear selector module (GSM). Diagnostic trouble codes (DTCs) are stored in the transmission control module (TCM) in the event of a fault.

GEAR SELECTOR ASSEMBLY

There are two types of gear selector assembly for the 4T65EV (-GT). There is one gear selector assembly with

seven positions and one with the Geartronic function.

Gear shift selector, seven positions

Fig. 170: Gear Shift Selector, Seven Positions
Courtesy of VOLVO CARS CORPORATION

The gear selector has seven positions with the following functions:

- **P** Park position
- **R** Back-up (reverse) position
- **N** Neutral position
- **D** Automatic shifting between all gears. (Does not apply when winter (W) mode is selected)
- **3** Fourth gear is blocked in this position
- **2** Only first and second gear function in this position

- **1** 2nd, 3rd and 4th gears are blocked in this position.

Geartronic gear shift selector

Fig. 171: Geartronic Gear Shift Selector
Courtesy of VOLVO CARS CORPORATION

Gear selector assemblies with Geartronic are unique in appearance and function. In addition to P/R/N/D modes they also have a "manual" (MAN) shifting mode.

The gear selector for Geartronic has the following functions:

- **P** Park position
- **R** Back-up (reverse) position
- **N** Neutral position

- **D** Automatic shifting between all gears. (Does not apply when the mode selector is in winter mode (W), for further information see, Function/Shifting program (Winter mode))
- **MAN** Manual shifting. There are three hall sensors on the gear selector module (GSM). A permanent magnet on the gear selector lever affects the output signals of the sensors to the gear selector module (GSM).

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the transmission control module (TCM). When ordering software, the hardware and the software in the car is compared to the data in the Volvo central database. If the comparison is OK the software is downloaded to the control module. If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

FUNCTION

CONTROLLING THE SHIFT SOLENOIDS WHEN SHIFTING

The solenoids are activated in a specific pattern to control shifting and the lock-up function. Solenoids S1 and S2 determine which gear is to be used at the time. Solenoids SL and STH determine engagement by adjusting the hydraulic line pressure of the transmission. The basic parameters for the different shifting points are the accelerator pedal (AP) position and the vehicle speed. The shift quality is decided by the control of torque and pressure control of the STH solenoid.

The pressurization of the clutches and the brakes are adjusted by reading the changes of the speed of the transmission input shaft during the shifting process and comparing them to the values calculated in the transmission control module (TCM).

Two shifting patterns can be selected, normal conditions and winter mode (selected using the button).

In normal mode shifting and lock-up occur at relatively low engine speeds to reduce fuel consumption. In the event of rapid accelerator pedal movements, the transmission control module (TCM) automatically shifts to sport mode.

Shifting patterns

Gear	Activated solenoid	
	S1	**S2**
1	ON	ON
2	OFF	ON
3	OFF	OFF
4	ON	OFF
R	ON	ON

SHIFTING PROGRAM

Economy mode

When driving at normal acceleration, the transmission control module (TCM) uses a pre-set shifting program, optimized to shift for economy driving. This shifting program is suitable for "normal" driving which provides earlier up shifts and lock-up. In addition the transmission oil pressure is adjusted to provide smooth gear engagement.

Sport mode

In the sport mode shifting program the shifting points are adjusted to provide the best possible performance. Downshifts occur earlier. The transmission control module (TCM) selects the shifting and lock-up points which provide the best possible performance. The transmission switches from economy mode to sport mode in step 1 or step 2 if the accelerator pedal (AP) is pressed down quickly. The conditions are that the throttle opens and the vehicle speed exceeds 50 km/h. As soon as the accelerator pedal (AP) is released to a certain level economy mode is resumed.

Kick-down program

At wide open throttle (WOT) the kick-down function is engaged which provides quick downshifts for maximum performance. In this way a boost of power is achieved when overtaking for example.

Winter mode

Winter mode is selected using the (W) button on the top panel of the gear selector assembly. Winter mode enables starting off in a high gear to prevent the wheels from spinning on a slippery surface. This mode can also be used in other difficult situations in which the driver needs more direct control over gear selection. Lock-up can be engaged in 1st and 2nd gear. The shifting pattern is optimized to minimize the number of shifts. Depending on the gear position, the following combinations can be obtained:

- **D** The car starts in 2nd gear. Automatic shifting between 2nd and 3rd gears occurs earlier than in Economy mode, D position
- **3** The car starts in 2nd gear. 4th gear is locked out
- **2** The car starts in 2nd gear. There is no up shifting or downshifting
- **1** The car starts in 1st gear. There is no up shifting or downshifting.

The W lamp on the dashboard lights when winter mode is selected.

If kick-down is activated in Winter mode, the transmission uses all gears for maximum performance.

OTHER MODES

Adaptation

The transmission control module (TCM) monitors each shift during all driving conditions to ensure consistent and smooth gear shifts. The control module does this by either lowering or increasing the hydraulic pressure used during the shift itself. The changed pressure levels are stored in the control module memory when the car has been switched off and are retrieved on start-up. This provides improved shifting comfort and increased

service life.

Adaptation occurs when the following conditions have been met:

- Throttle opening is steady
- Oil temperature between 50 °C and 110 °C.

Temperature controlled lock-up

If the transmission temperature increases abnormally as a result of heavy load under high ambient temperature conditions, the torque converter lock-up function is activated as often as possible (temperature controlled lock-up). This reduces slippage and the generation of heat in the transmission. If the temperature is below +20 °C the lock-up function does not engage in order to increase the temperature of the oil more rapidly.

SHIFTING USING GEARTRONIC

Fig. 172: Checking Shift Positions
Courtesy of VOLVO CARS CORPORATION

When the gear selector is moved to the Geartronic position (MAN) the automatic transmission remains in hydraulic position D, but when the gear selector is moved upwards (+) the gear selector module (GSM) transmits a signal to the transmission control module (TCM) to shift up. When the gear selector is moved downwards (-) a signal is transmitted to the transmission control module (TCM) to shift down. The driver information module (DIM) switches the symbol in the combined instrument panel from D to the current gear,

for example 3, when the gear selector is in the MAN position. A signal is sent to the gear selector module (GSM) to light the M LED and switches off the other LEDs. The transmission control module (TCM) determines if shifting can be carried out and the driver information module (DIM) indicates the current gear. If shifting is permitted the solenoids are activated according to each specific gear pattern.

However, in certain situations the transmission control module (TCM) assumes the shifting decision. The following applies:

- When stationary only 1st, 2nd and 3rd gears can be selected. 4th gear can be selected at speeds exceeding 30 km/h
- Automatic down shifting occurs for all gears below a certain speed. Example: 2nd gear is selected. Automatic down shifting occurs when shifting from 2nd gear to 1st at 2 km/h if the speed, before this has exceeded 25 km/h. in other cases 2nd gear is retained. For example, when 3rd gear is engaged despite the car being stationary
- Manual up shifting is required after automatic down shifting. Kick-down is not available in the Geartronic-position (MAN)
- The permitted speed for manual down shifting corresponds to those for kick-down up shifting, i. e. engine speed at approximately 6, 000 rpm
- If the transmission temperature becomes too high the transmission control module (TCM) determines the shift position. The purpose is to maintain a gear where lock-up is possible at the current speed
- Lock-up is possible in 3rd and 4th gears. (1st and 2nd gears do not have lock-up).

Other

In the MAN position a signal about the lever position is generated for the gear selector module (GSM) as follows:

For each of the three gear selector positions a hall sensor is mounted on the printed circuit board for the gear selector control module (GSM). A permanent magnet on the lever affects the output signals from the sensors to the control module. The control module can read off the position of the lever through the differences in the signal characteristics.

SHIFT-LOCK

Fig. 173: Identifying Shift-Lock
Courtesy of VOLVO CARS CORPORATION

To avoid any chance of the gear selector inadvertently moving from the P position, the car is also equipped with an electrically operated shift-lock function. This locks the interlock pin in the gear selector lever in the shift-lock section, locking the selector lever in the P position. To move the gear selector from the P position, the ignition must be switched on and the brake pedal depressed. (The stop lamp switch is activated.). The central electronic module (CEM) reads the position of the brake pedal via direct connection to the brake pedal sensor and transmits a signal to the gear selector module (GSM) to deactivate the solenoid in the gear lever selector. The solenoid lock pin is pushed in and the gear selector lock button can be pressed down as usual to select another gear. When the ignition is in position "0", the solenoid is deactivated. In this position the gear selector is mechanically locked by the ignition switch interlock.

IGNITION SWITCH INTERLOCK

Fig. 174: Identifying Ignition Switch Interlock
Courtesy of VOLVO CARS CORPORATION

An interlock and security feature (ignition switch interlock) is mechanically connected to the ignition switch by a cable. The ignition switch interlock is controlled by the position of the lock cylinder in the ignition switch and by the position of the gear selector. This means that the gear selector must be in the P position for the ignition key to be removed from the ignition switch. The ignition key must be turned to position I or II before the lever can be moved from the P-position. The ignition switch interlock is used only in combination with shift-lock.

PARK / NEUTRAL POSITION (PNP) FUNCTION

The gear-shift position sensor has a park / neutral position (PNP) function to prevent the engine being started with a gear selected.

This function prevents the engine being started unless the P or N positions are selected. This prevents the car from lurching forwards when started.

ADAPTATION DATA

There is a function for resetting adaptation in the transmission control module (TCM) which can be activated via VIDA vehicle communication. This must be carried out after replacing internal components, such as the valve housing or a solenoid, or when replacing the entire transmission.

COUNTER FOR TRANSMISSION FLUID DATA

A counter for transmission oil quality is built into the software for the transmission control module (TCM). The counter counts up the amount of time the oil is above a certain temperature. When the counter has reached the maximum value, the diagnostic trouble code (DTC) for an oil change is stored in the control module. When replacing transmission fluid, the counter must be reset to prevent a diagnostic trouble code (DTC) being stored incorrectly. This applies when the transmission fluid is changed and when the fluid is changed during a repair.

The reset function is activated via the VIDA vehicle communication socket.

EMERGENCY MODE IN THE EVENT OF A FAULT

If the transmission control module (TCM) detects a permanent fault, an emergency mode is activated. The transmission control module (TCM) then implements corrective action to protect the transmission, while leaving the car in the best possible drivable condition. Minor malfunctions do not activate an emergency program. There are different programs depending on the type of fault:

- Emergency mode
- Limp home mode.

Emergency mode is activated for minor faults and the Limp home mode for the most serious faults. If the malfunction is intermittent, the transmission control module (TCM) returns to normal operation the next time the ignition is switched on.

Emergency mode

A text message is displayed in the combined instrument panel for diagnostic trouble codes (DTCs) stored in the transmission control module (TCM).

The transmission shifts in all gears but transmits no signal to the lock-up solenoid. This means that lock-up is not available.

Limp home mode

A text message is displayed in the combined instrument panel for diagnostic trouble codes (DTCs) stored in the transmission control module (TCM).

The transmission control module (TCM) interrupts the activation of all solenoids. This means that no shifting is possible. The transmission only functions in 3rd gear and back-up (reverse) gear.

No regulation of line pressure solenoid STH. Maximum system pressure constantly which results in harsh meshing and harsher shifts when engaging P-R, N-R and N-D. This can also result in a whining noise from the

transmission pump.

SYSTEM OVERVIEW

OVERVIEW

Fig. 175: Transmission Control Module (TCM), 4T65EV-GT System Overview
Courtesy of VOLVO CARS CORPORATION

4T65EV (-GT) is an electronically controlled automatic gearbox with an optional lock-up function on the three highest gears. The gearbox control module (TCM) adapts the gear shifts so that the correct gear is always selected to match the driving style, engine load, the wishes of the driver, vehicle speed etc. This ensures good fuel economy and increased comfort through smoother gear changes and lower sound levels.

The gearbox control module (TCM) receives information about the desired gear position and driving mode from the driver. Unlike with a purely hydraulically controlled gearbox, this information, in conjunction with the signals from a number of sensors in the gearbox and the engine control system, allows the control module to calculate the optimal shifting points and engagement of torque converter lock-up. The control module allows for small changes in the operating conditions and adapts the various gearbox functions to ensure that the correct gear is always selected in relation to the driving mode selected by the driver.

This adaptability guarantees smooth and consistent gear shift quality throughout the operational life of the gearbox.

In order to precisely determine the gear shift and lock-up engagement points based on the driving mode selected, the control module receives information about the following:

- Selected gear position - from the gear-shift position sensor, which is positioned on the inside of the gearbox housing
- Selected driving mode - reactive function programmed in the control module which is controlled by the speed at which the accelerator pedal is depressed. Quick "pedal movement" = sport mode.
- Vehicle speed - from the brake control system via the Controller area network (CAN)
- Gearbox input shaft rpm - from the gearbox speed sensor
- The gearbox output shaft rpm - from the gearbox output speed sensor
- The engine speed (RPM) and torque signal - from the engine management system via the control area network (CAN)
- If the brake pedal is depressed - from the brake system via the control area network (CAN)
- Accelerator pedal (AP) and movement speed - from the engine management system via the control area network (CAN)
- The gearbox fluid temperature - from the temperature sensor in the gearbox.

COMPONENTS

Fig. 176: Locating Transmission Input, Output, Oil Temperature, Gear-Shift Position And Pressure Sensors.
Courtesy of VOLVO CARS CORPORATION

The following components are included in the control system for the automatic gearbox (4T65EV):

- The gearbox control module (TCM) - Controls the solenoids
- Shift solenoid, S1 - Controls shifting in the gearbox
- Shift solenoid, S2 - Controls shifting in the gearbox
- Lock-up solenoid, SL - Controls the torque converter lock-up function
- Line pressure solenoid, STH - Controls the gearbox line pressure
- Gearbox input speed sensor (input shaft speed) (5) - Provides the gearbox control module (TCM) with information about the input shaft speed. This is measured on the turbine side of the torque converter
- Speed sensor (output shaft speed) (7) - Provides the gearbox control module (TCM) with information about the output shaft speed from the gearbox
- Temperature sensor (6) - Provides the gearbox control module (TCM) with information about the oil temperature of the gearbox
- Gear-shift position sensor (8) - Provides the gearbox control module (TCM) with information about the selected gear position (PRND321)
- Pressure sensor lock-up (9) - Provides the gearbox control module (TCM) with information about the gearbox oil pressure and selected gear
- Gear selector module (GSM) - Provides the gearbox control module (TCM) with information about the gear selector position: If the selector is in position D or in the Geartronic mode, or if up or down shifting occurs in the Geartronic position.

SIGNALS

The table below summarizes the input signals to and output signals from the gearbox control module (TCM). The signal types are divided into directly connected signals, serial communication and Controller area network (CAN) communication. The following illustration displays the same information with the Volvo component designations.

Input signals	Output signals
Directly connected: **Speed sensor, input shaft** (7/61). Provides information about the gearbox input speed. Used to calculate the shifting process and to run diagnostics for the hydraulic/mechanical functions in the gearbox. **Speed sensor, output shaft** (7/62). Provides information about the gearbox output speed. Used to calculate the vehicle speed and to run diagnostics for the hydraulic/mechanical functions in the gearbox. **Temperature sensor** (7/74). Provides information about the gearbox oil temperature. **Gear-shift position sensor** (3/71). Provides the gearbox control module (TCM) with information	**Directly connected:** (power supply unless otherwise stated) **Shift solenoids, S1-S2** . The gearbox control module (TCM) checks which gear is active by activating the solenoids in different patterns. **Lock-up solenoid, SL** . Activates the Lock-up function. **Line pressure solenoid, STH** . Adjusts the line pressure of the gearbox when shifting.

about the selected gear position of the gearbox. Enables starting only in position P and N. Four trailing contacts are grounded in a unique pattern for each gear. **Pressure sensor Lock-up** . Provides the gearbox control module (TCM) with information about the gearbox oil pressure and selected gear.	
Via serial communication: **Gear selector module (GSM)** (3/156). Provides information about the gear selector position: If the selector is in position D or in the Geartronic mode, or if up or down shifting occurs in the Geartronic position.	**Via serial communication:** **Gear selector module (GSM)** (3/156). Controls the solenoid for the shift-lock function (8/36). Activated on request by the central electronic module (CEM) (4/56).
Via Controller Area Network (CAN) communication: **Engine control module (ECM)** (4/46). Accelerator pedal (AP) position, used to calculate the gear-shift timing. **Steering wheel module (SWM)** (3/130), via the central electronic module (CEM) (4/56). Cruise control, used to calculate acceleration depending on the position of the Resume and Set buttons. **Brake control module (BCM) / Anti-lock brake system module (ABS)** (4/16). The difference in speed between the right and left-hand wheels. Requests a reduction in torque if the differential speed is too high. **Engine control module (ECM)** (4/46): • Brake lamp switch ON/OFF, used during the torque converter lock-up function • Engine coolant temperature (ECT), used to diagnose the gearbox temperature sensor • Engine speed (RPM) >400 rpm = engine running. Used to start the transmission oil pressure and diagnostic functions • Engine speed (RPM), used to check the slipping rate of the torque converter and the pressure build up, affecting the shifting comfort • Kick-down. If the accelerator pedal (AP) is depressed and the throttle is wide open the engine control module (ECM) transmits a signal to the gearbox control module (TCM) about kick-down • Current engine torque, used to check the line	**Via Controller Area Network (CAN) communication:** **Brake control module (BCM) / Anti-lock brake system module (ABS)** (4/16): • Current gear, used to transmit a signal so there is no STC (Stability and traction control) when shifting • Vehicle speed, used as reverse. **Engine control module (ECM)** (4/46): • Gearbox temperature, used to compensate increased load at low oil temperatures • Selected gear, used by the engine so that it can compensate for different loads • Lock-up, used by the engine so that it can compensate for different loads • Next gear ordered by the gearbox control module (TCM), used by the engine so that it can compensate for different loads • Torque reduction during shifting. This is achieved by retarding the ignition • Torque limiting request, the engine limits the engine torque depending on the current gear. This is achieved by controlling the throttle opening • Lights the malfunction indicator lamp (MIL) in the driver information module (DIM). Checking the malfunction indicator lamp (MIL), lights the lamp in the event of

pressure.	emission related faults. **Driver information module (DIM)** (5/1): • Current gear selector lever position. Used to show the lever position in the driver information module (DIM) • Via the central electronic module (CEM), checking the warning lamps. Lights the orange/yellow warning lamp in the event of a fault • Via the central electronic module (CEM), text message in the driver information module (DIM). The driver can receive up to five error messages from the gearbox control module (TCM). **Rear electrical module (REM)** (4/58). The gearbox control module (TCM) transmits a signal via the central electronic module (CEM) to light the reversing lamp.

TCM DIAGNOSTIC FUNCTIONS

OVERVIEW

Fig. 178: Identifying Transmission Control Module
Courtesy of VOLVO CARS CORPORATION

The control unit has built-in diagnostics, Volvo Diagnostics, which continually monitor the system and the input and output signals.

DIAGNOSTIC TROUBLE CODES

If the control unit detects a fault, it stores a diagnostic trouble code. If, for any reason, a fault disappears after the diagnostic trouble code has been permanently stored in the control unit, information about the trouble code still remains in the control unit.

READING AND ERASING DIAGNOSTIC TROUBLE CODES

Stored diagnostic trouble codes can be read and erased using this facility.

Erasing diagnostic trouble codes can only be done when all the diagnostic trouble codes have been read at least once.

READING INPUT AND OUTPUT SIGNALS

Status of control unit input and output signals can be continually read using this facility.

For more information about parameters, see **DESCRIPTION OF PARAMETERS**.

ACTIVATION OF COMPONENTS

Using this facility, components can be activated to check their function.

For more information about activations, see **DESCRIPTION OF ACTIVATIONS** .

READING THE CONTROL UNIT IDENTIFICATION

VIDA identifies control units by reading the number of codes from the control unit memory.

The codes contain information on the control unit as follows:

- hardware component number (control unit without software)
- hardware series number (control unit without software)
- software component number
- diagnostic software component number

DESCRIPTION OF PARAMETERS

PARAMETERS, STATUS

GENERAL

Certain values deviate from those contained in the signal specifications, see **SIGNAL DESCRIPTION. TRANSMISSION CONTROL MODULE (TCM)** . This is because read off values are calculated and filtered by the control module. In certain cases the engine must be running to obtain the relevant values.

GEAR-SHIFT POSITION SENSOR POSITION

P/R/N/D/4/3/L = normal gear positions.

OR/OD/OL = Undefined R, D or L positions. The signals from the gear-shift position sensor are outside the normal range but this not interpreted as a fault. This may be because the gear selector is between positions or that the gear-shift position sensor is incorrectly adjusted.

FAULT = the gear-shift position sensor has transmitted the wrong combination of signals and a diagnostic trouble code (DTC) has been stored.

GEAR-SHIFT POSITION SENSOR SIGNAL A

LOW = The signal is grounded in the gear-shift position sensor

HIGH = The signal is not grounded in the gear-shift position sensor

Position P: Signal A= LOW

Position R: Signal A= LOW

Position N: Signal A = HIGH

Position D: Signal A = HIGH

Position 3: Signal A= LOW

Position L: Signal A= LOW

GEAR-SHIFT POSITION SENSOR SIGNAL B

LOW = The signal is grounded in the gear-shift position sensor

HIGH = The signal is not grounded in the gear-shift position sensor

Position P: Signal B= HIGH

Position R: Signal B = LOW

Position N: Signal B = LOW

Position D: Signal B = LOW

Position 3: Signal B = LOW

Position L: Signal B= HIGH

GEAR-SHIFT POSITION SENSOR SIGNAL C

LOW = The signal is grounded in the gear-shift position sensor

HIGH = The signal is not grounded in the gear-shift position sensor

Position P: Signal C= HIGH

Position R: Signal C= HIGH

Position N: Signal C= HIGH

Position D: Signal C= LOW

Position 3: Signal C= LOW

Position L: Signal C= LOW

GEAR-SHIFT POSITION SENSOR SIGNAL PA

LOW = The signal is grounded in the gear-shift position sensor

HIGH = The signal is not grounded in the gear-shift position sensor

Position P: Signal C= LOW

Position R: Signal C= HIGH

Position N: Signal C= LOW

Position D: Signal C= HIGH

Position 3: Signal C= LOW

Position L: Signal C= HIGH

QUICK SHIFT FUNCTION FROM THE GEAR SELECTOR MODULE

Applies only to 4T65EV-GT.

The value indicates whether the quick shift mode is selected or not.

ON = Gear selector in position P/R/N/D

ON = Gear selector in Quick shift mode

QUICK SHIFT SHIFTING FROM GEAR SELECTOR MODULE

Applies only to 4T65EV-GT.

The value indicates the quick shift mode which the gear selector module transmits to the transmission control module (TCM).

No shift = no quick shift function

Increase gear = shift up

Decrease gear = shift down

QUICK SHIFT STATUS ACCORDING TO TRANSMISSION CONTROL MODULE

Applies only to 4T65EV-GT.

This value indicates the shifting program selected by the control module based on the signal from the gear selector.

Normal = P/R/N/D

Quick shift = Quick shift

WINTER MODE STATUS

This value indicates the shifting program selected by the control module based on the signal from the mode selector. W = Winter mode.

Engaged = Winter mode engaged

Disengaged = Winter mode disengaged

CURRENT GEAR (ACCORDING TO GEAR RATIO)

- R, no lock-up
- Gear 1, no lock-up
- Gear 2, no lock-up
- Gear 3, no lock-up
- Gear 4, no lock-up
- Gear 5, no lock-up
- Gear 2, lock-up
- Gear 3, lock-up
- Gear 4, lock-up
- Gear 5, lock-up

NEW GEAR (ACCORDING TO SOLENOIDS)

- R, no lock-up
- Gear 1, no lock-up
- Gear 2, no lock-up
- Gear 3, no lock-up
- Gear 4, no lock-up
- Gear 5, no lock-up
- Gear 2, lock-up
- Gear 3, lock-up
- Gear 4, lock-up
- Gear 5, lock-up

SHIFT SOLENOID STATUS S1

OFF = The solenoid is not activated

ON = The solenoid is activated

SHIFT SOLENOID STATUS S2

OFF = The solenoid is not activated

ON = The solenoid is activated

LOCK-UP SOLENOID SL STATUS

OFF = The lock-up solenoid is not activated

ON = The lock-up solenoid is activated

LOCK-UP PRESSURE SWITCH

Applies only to 4T65EV-GT.

The pressure switch is affected by the transmission line pressure. The control module uses the signal from the pressure switch to check whether the lock-up solenoid is activated when the control module has requested lock-up.

OFF = No lock-up activated

ON = Lock-up activated

STOP (BRAKE) LAMP SWITCH

The engine control module (ECM) transmits a signal on the Control area network (CAN) indicating whether the stop (brake) lamp switch is activated or not. The transmission control module (TCM) uses the signal to disconnect the lock-up function when braking in order to avoid jolts in the transmission.

OFF = Stop (brake) lamp switch unaffected

ON = Stop (brake) lamp switch affected

KICKDOWN

The engine control module (ECM) transmits a signal indicating the accelerator pedal (AP) position. During rapid acceleration, with the accelerator pedal (AP) depressed to approximately 87 %, the transmission control module (TCM) receives a signal about kickdown.

OFF = Kickdown is not activated

ON = Kickdown is activated

TCM DIAGNOSTIC TROUBLE CODES (DTCS) STATUS

The value indicates whether there are any diagnostic trouble codes (DTCs) stored in the transmission control module (TCM).

- At least one diagnostic trouble code (DTC) stored

- No diagnostic trouble code (DTC) stored

TCM DIAGNOSTIC CHECK STATUS

The value indicates whether the transmission control module (TCM) has carried out a complete diagnosis.

- At least one diagnostic test not completed
- All diagnostic tests complete

PARAMETERS, VALUE

ENGINE SPEED (RPM)

The engine control module (ECM) transmits the engine speed (RPM) on the Control area network (CAN) from which the transmission control module (TCM) retrieves the signal which it then compares with its own speed sensor signal.

Measurement range: 0 - 8191 rpm

Idling speed: 850 rpm

TRANSMISSION SPEED SENSOR, INPUT SPEED

The speed can be generated with the engine idling and the gear selector in P/N position. If the gear selector is in any other position, a gear is engaged and the transmission input shaft is connected to the output shaft and an RPM will not be indicated until the car is driven. Depending on slippage in the torque converter the transmission speed and the engine speed will differ when the lock-up function is not engaged. With lock-up engaged the transmission speed should be the same as engine speed (RPM).

Measurement range (rpm): 0 -

Peak = 14 mA

Trough = 7 mA

TCM SPEED SENSOR, CALCULATED SPEED

The control module receives a signal from the transmission speed sensor which is affected by a toothed pulse wheel and calculates the vehicle speed based on the signal. The speed sensor is an "active" sensor, magnet resistive with a current activated interface????. The speed is directly proportional to the frequency.

Measurement range: 0 km/h - top speed

Peak = 14 mA

Trough = 7 mA

VEHICLE SPEED ABS

The ABS control module transmits a signal indicating the vehicle speed on the Control area network (CAN) from where the transmission control module retrieves the signal. The transmission control module (TCM) compares it with the signal from the transmission speed sensor.

Measurement range: 0 km/h - top speed

Peak = 14 mA

Trough = 7 mA

THROTTLE, POSITION

The engine control module (ECM) transmits the accelerator pedal (AP) position on the Control area network (CAN) from where the transmission control module (TCM) retrieves the signal. The signal is used by the transmission to activate the kickdown function.

Measurement range: 0 - 100 %

>87 % = kickdown

CALCULATED BATTERY VOLTAGE

The value indicates the calculated battery voltage at the control module.

Measurement range: 0.0 -25.5 V

BATTERY VOLTAGE

The value indicates battery voltage at the control module.

Measurement range: 0.0 -25.5 V

OIL TEMPERATURE SENSOR SIGNAL

The value indicates the oil temperature sensor signal. Voltage decreases with increased sensor temperature.

Measurement range: 0.0 - 5.0 V

AW 50-42:

Cold transmission (+20°C): approximately 2.4 V

Hot transmission (+100°C): 0.3 -0.5 V

4T65EV/EV-GT:

Cold transmission (+20°C):??? V

Warm transmission (+100°C):??? V

OIL TEMPERATURE

The transmission control module (TCM) calculates the temperature from the oil temperature sensor signal.

Measurement range: -60 - +180°C

LINE PRESSURE SOLENOID STH AMPERAGE

The value indicates the amperage passing through the solenoid circuit. A lower amperage gives a higher reference pressure, which gives a higher line pressure. Solenoid control is directly dependent on the throttle sensor signal. The higher the signal from the throttle sensor the lower the amperage through the solenoid and therefore the higher the line pressure.

Measurement range: 0.0 -1.5 A

Normal value at closed throttle: 280 mA

LINE PRESSURE SOLENOID STH CONTROL

Line pressure solenoid STH controls the reference pressure for the transmission. The reference pressure in turn controls the system pressure in the transmission so that the system pressure in gear D varies between 0.28 - 1.2 MPa (R position: 0.5 - 1.8 MPa). Solenoid control is directly dependent on the signal from the throttle position (TP) sensor. The higher the signal from the throttle position (TP) sensor the greater the reference pressure and therefore line pressure.

Measurement range: 0 - 100 %

0 % control, minimal reference pressure, gives lowest line pressure.

100 % control, maximum reference pressure, gives highest line pressure.

LOCK-UP SOLENOID SL, AMPERAGE

The value indicates the amperage through the solenoid circuit. Control of the solenoid circuit depends on:

- The gear position selected
- Vehicle speed
- The transmission speed - from the transmission speed sensor
- The engine speed (RPM) and load - from the fuel injection system control module
- Throttle opening
- If the brake pedal is depressed - from the stop (brake) lamp switch
- Transmission temperature

TORQUE CONTROL

The control module requests torque-limiting from the engine control module (ECM) in order to limit the torque immediately before shifting to improve shifting quality. The torque is limited by the ignition and fuel injection.

Measurement range: -512 - +512 Nm

ENGINE TORQUE

The transmission control module (TCM) requests torque-limiting from the engine control module (ECM) in order to limit torque immediately before shifting. The signal is used to inform the ABS control module when the driver has requested torque reduction. This is so that the torque will return to the correct level after reduction.

Measurement range: -512 - +511 Nm

511 = No torque limiting request

TORQUE REDUCTION WHEN SHIFTING

The transmission control module (TCM) requests torque-limiting from the engine control module (ECM) in order to limit torque immediately before shifting. Torque limiting can occur at three different levels: 25 %, 35 % or 45 %. Limitation lasts for less than 1 second.

0 = No torque limiting requested

25, 35, 45 % = Torque limiting requested

TORQUE LIMITING REQUESTED

The transmission control module (TCM) requests torque-limiting from the engine control module (ECM) in order to limit torque immediately before shifting. The signal is used to inform the ABS control module when the driver has requested torque reduction. This is so that the torque will return to the correct level after reduction.

Measurement range: -512 - +511 Nm

511 = No torque limiting request

ENGINE CONTROL MODULE (ECM) ENGINE COOLANT TEMPERATURE (ECT)

The engine control module (ECM) transmits a signal indicating the engine coolant temperature (ECT) on the Control area network (CAN). The automatic transmission uses the signal to govern lock-up.

Measurement range: -60 - +195°C

TEXT TRANSMITTED TO THE DRIVER INFORMATION MODULE

In the event of a service reminder indicator fault, the transmission control module (TCM) transmits a message to the driver information module. The text is displayed in the combined instrument panel display.

1 = TRANSMISSION SERVICE URGENT

2 = TRANSMISSION SERVICE REQUIRED

3 = TRANSMISSION FIX NEXT SERVICE

4 = TRANSMISSION OIL TEMP HIGH

5 = CHANGE TRANS OIL AT NEXT SERVICE

TRANSMISSION CONTROL MODULE (TCM) (AW50/51 AWD; AW55-50/51SN; 2003-2007)

DESIGN

CONTROL MODULE

The transmission control module (TCM) is positioned in an air cooled plastic box in the engine compartment together with the engine control module (ECM).

SHIFT SOLENOIDS S1, S2, S3, S4 AND S5

Fig. 180: Identifying Shift Solenoids S1, S2, S3, S4 & S5
Courtesy of VOLVO CARS CORPORATION

The shift solenoids S1, S2, S3, S4 and S5 are positioned in the valve body in the gearbox control system, which is mounted on the front edge of the gearbox. The shift solenoids (on/off type), consist of an electrical coil which controls a hydraulic valve. The solenoids are supplied with 12 V via the transmission control module (TCM) and grounded in the control system. The shift solenoids control shifting and the transmission control module (TCM) determines which gear is to be used by activating them in different patterns.

There is a diagnostic for the shift solenoids.

LOCK-UP SOLENOID, SLU

Fig. 181: Identifying Lock-Up Solenoid, SLU
Courtesy of VOLVO CARS CORPORATION

The lock-up-solenoid, SLU is located in the gearbox control system, which is mounted on the front edge of the gearbox.

The lock-up-solenoid, SLU consists of an electric coil that controls a hydraulic valve. The solenoid is controlled, like all linear solenoids in the gearbox, by a pulsed (PWM) current with a frequency of 300Hz and grounded via the Transmission Control Module (TCM). The average value on the current signal that deploys the solenoid varies between 0.1 A and 1 A and the demand controls the deployment.

The solenoid controls the torque converter's Lock-up engagement. Engagement occurs by the solenoid pulsing, which gives a smooth engagement of the lock-up function. The solenoid allows the torque converter to work in one of three positions:

- Open
- Controlled slipping
- Locked.

The hydraulic function of the solenoid is linear.

There is a diagnostic for the lock-up solenoid.

LINE PRESSURE SOLENOID, SLS

Fig. 182: Identifying Line Pressure Solenoid SLS
Courtesy of VOLVO CARS CORPORATION

The line pressure solenoid, SLS is in the gearbox control system, which is mounted on the front edge of the gearbox. The line pressure solenoid, SLS consists of an electrical coil which controls a hydraulic valve. The solenoid is controlled by pulse width modulation (PWM) voltage and is grounded via the transmission control module (TCM). The hydraulic function of the solenoid is linear. The hydraulic valve is controlled by the varied current which is the result of the current pulse conditions. During high pulse conditions, (at high currents (approximately 1 A)) the line pressure is low. During low pulse conditions (at low currents) the line pressure is high. In the event of an open-circuit the line pressure reaches maximum which causes hard shifting. The hydraulic valve is then completely open.

There are diagnostics for the solenoid.

LINE PRESSURE SOLENOID, SLT

Fig. 183: Identifying Line Pressure Solenoid
Courtesy of VOLVO CARS CORPORATION

The line pressure solenoid, SLT is in the gearbox control system, which is mounted on the front edge of the gearbox. The line pressure solenoid, SLT consists of an electric coil which controls a hydraulic valve. The solenoid is controlled by pulse width modulation (PWM) voltage and is grounded via the control module. The solenoid is linear. The hydraulic valve is controlled by the varied current which is the result of the current pulse conditions. During high pulse conditions, (at high currents (approximately 1 A)) the line pressure is low. During low pulse conditions (at low currents) the line pressure is high. The solenoid also engages and disengages neutral control. In the event of an open-circuit the line pressure reaches maximum which causes hard shifting. The hydraulic valve is then completely open.

There are diagnostics for the solenoid.

GEARBOX INPUT SPEED SENSOR (SPEED OF THE INPUT SHAFT)

Fig. 184: Identifying Transmission Input Speed Sensor
Courtesy of VOLVO CARS CORPORATION

The gearbox input speed sensor (speed of the input shaft) is on the top of the gearbox housing. The sensor is an active sensor and is supplied with 12 V. When the pulse wheel on clutch C1 rotates, the sensor generates a pulsed current (quadratic wave) where the strength of the current depends on the position of the pulse wheel. The signals from the coils in the sensor are then affected by a magnetic resistance element, which generates a current which oscillates between 7 mA and 14 mA, and whose frequency increases with speed. Using the signal from the sensor, the transmission control module (TCM) calculates the gearbox speed, unit rpm.

The transmission control module (TCM) uses information about the input shaft speed to calculate the torque reduction to be requested from the engine control module (ECM) when shifting. The value is also used to compare the engine speed (RPM) with the speed of the input shaft in order to calculate the slipping rate of the torque converter. The value is also compared with the gearbox speed sensor signal in order to calculate the actual gear ratio. This is done to check whether the value corresponds to the expected gear ratio.

There are diagnostics for the gearbox input speed sensor.

GEARBOX OUTPUT SPEED SENSOR (SPEED OF THE OUTPUT SHAFT)

Fig. 185: Identifying Transmission Output Speed Sensor
Courtesy of VOLVO CARS CORPORATION

The gearbox output speed sensor (speed of the output shaft) is on the reverse of the gearbox housing. The sensor provides signals to the transmission control module (TCM) about the vehicle speed. The output shaft speed sensor is an active sensor and is supplied with 12 V. When the pulse wheel (wheel for shift-lock) rotates the sensor generates a pulsed current (quadratic wave) where the strength of the current depends on the position of the pulse wheel. The signals from the coils in the sensor are then affected by a magnetic resistance element, which generates a current which oscillates between 7 mA and 14 mA, and whose frequency increases with speed. The control module calculates the gearbox output speed using the signals from the sensor. The signal is compared with the signal from the gearbox input speed sensor and is used to calculate the gear ratio and is also used for diagnostics.

There are diagnostics for the gearbox output speed sensor.

OIL TEMPERATURE SENSOR

Fig. 186: Identifying Oil Temperature Sensor
Courtesy of VOLVO CARS CORPORATION

The temperature sensor is an NTC sensor. The temperature sensor is on the gearbox control system inside the side cover. It gauges the temperature of the gearbox fluid in the sump. The temperature sensor is integrated in the cable harness. The temperature sensor is supplied with 5 V and is grounded via the transmission control module (TCM). The control module can determine the gearbox fluid temperature by measuring the voltage drop above the NTC resistance of the sensor. The control module stores the time the temperature has been within a certain temperature range. If a certain temperature and time has been exceeded, a diagnostic trouble code (DTC) indicating that a oil change is necessary is stored.

There are diagnostics for the temperature sensor.

GEAR-SHIFT POSITION SENSOR

Fig. 187: Gear-Shift Position Sensor
Courtesy of VOLVO CARS CORPORATION

The gear-shift position sensor is mounted on the top of the gearbox housing, on the gear shift linkage rod. The gear selector contains a Park / Neutral position (PNP) switch and connectors which inform the transmission control module (TCM) about which gear is selected and if the reverse gear is selected so that the reversing lamps can be lit. The gear-shift position sensor is a position switch which is supplied via +15. A number of trailing contacts supply power to the sensor outputs. The combination of pins A, B, C and PA indicate the current gear selector position (see the table below). The trailing contacts can either be closed or open.

There are diagnostics for the gear-shift position sensor.

	A	B	C	PA
P	-	●	●	-

Fig. 188: Identifying The Gear-Shift Position Sensor Table
Courtesy of VOLVO CARS CORPORATION

Table for the gear-shift position sensor

The value indicates the position of the gear-shift position sensor (A, B, C and PA), see the table.

• = High signal (open)

- = Low signal (grounded)

GEAR SELECTOR MODULE (GSM)

Fig. 189: Gear Selector Module
Courtesy of VOLVO CARS CORPORATION

The gear selector assembly is in the tunnel console. It is mechanically connected to the gearbox by a cable which moves the gear valve in the gearbox control system. The gear selector module (GSM) is positioned on the top panel of the gear selector assembly. The gear selector module (GSM) uses serial communication to communicate with the transmission control module (TCM) to light the gear position indicator. The indication occurs via LEDs in the top panel.

The gear selector control module (GSM) communicates with the central electronic module (CEM) to activate the shift-lock. The shift-lock solenoid power supply and ground is directly connected to the gear selector module (GSM).

The "W" switch in the gear selector assembly top panel is positioned on the printed circuit board for the gear selector module (GSM) and activates Winter mode.

There are diagnostics for the gear selector module (GSM). Diagnostic trouble codes (DTCs) are stored in the transmission control module (TCM) in the event of a fault.

GEAR SELECTOR ASSEMBLY FOR AW55-50

There are two new types of gear selector assembly for the AW55-50. There is one gear selector assembly with

seven positions and one with the Geartronic-function.

Gear selector assembly with 7 positions

Fig. 190: Gear Selector Assembly With 7 Positions
Courtesy of VOLVO CARS CORPORATION

The gear selector has seven positions with the following functions:

- **P** Park.
- **R** Reverse.
- **N** Neutral.
- **D** Automatic gearshift between all gears (does not apply when the mode selector is in winter mode (W)). For more information see, Function/Shifting program/Winter mode.
- **4** Fifth gear is blocked in this mode

- **3** Fourth and fifth gear are blocked in this mode
- **L** Only first and second gear function in this mode. (Speed variation depends on which engine the gearbox is working with and does not apply when the mode selector is in winter mode (W), for further information see, Function/Shifting program/Winter mode).

Gear selector assembly with Geartronic function

Fig. 191: Gear Selector Assembly With Geartronic Function
Courtesy of VOLVO CARS CORPORATION

The gear selector assembly with Geartronic has a unique appearance and function. In addition to P/R/N/D modes it also has "manual" (MAN) shifting mode.

The gear selector for Geartronic has the following functions:

- **P** Park position
- **R** Reverse position
- **N** Neutral position
- **D** Automatic gearshift between all gears. (Does not apply when the mode selector is in winter mode (W), for further information see, Function/Shifting program/Winter mode)
- **MAN** Manual shifting. There are three hall sensors on the gear selector module (GSM). A permanent magnet on the gear selector lever affects the output signals of the sensors to the gear selector module (GSM).

DOWNLOADING SOFTWARE AND REPLACING THE CONTROL MODULE

New software can be downloaded into the transmission control module (TCM). When ordering software, the hardware and the software in the car is compared to the data in the Volvo central database. If the comparison is OK the software is downloaded to the control module. If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded.

FUNCTION

CONTROLLING THE SHIFT SOLENOIDS WHEN SHIFTING

Shifting and the lock-up function is controlled by activating the solenoids in a specific pattern. The solenoids S1-S5 determine which gear is to be used and the SLS, SLU and SLT solenoids determine engagement by adjusting hydraulic line pressure. The basic parameters for the different shifting points are the accelerator pedal (AP) position and the vehicle speed. The shift quality is decided by the control of torque.

The pressurization of the clutches and the brakes are adjusted by reading the changes of the speed of the transmission input shaft during the shifting process and comparing them to the values calculated in the transmission control module (TCM).

Two shifting patterns can be selected, normal conditions and winter mode (selected using the button).

In normal mode shifting and lock-up occur at relatively low speeds to reduce fuel consumption. In the event of rapid accelerator pedal movements, the transmission control module (TCM) automatically shifts to sport mode.

Shifting patterns

Gear	Activated solenoid					
	S1	**S2**	**S3**	**S4**	**S5**	**SLS**
1	ON	ON	ON	OFF	OFF	OFF
2	OFF	OFF	ON	OFF	OFF	ON
3	OFF	OFF	ON	ON	OFF	ON
4	OFF	OFF	OFF	ON	OFF	ON
5	OFF	ON	OFF	ON	OFF	ON
R	OFF	OFF	ON	OFF	ON	OFF

SHIFTING PROGRAM

Economy mode

When driving at normal acceleration the transmission control module (TCM) uses a pre-set shifting program, optimized to shift for economy driving. This shifting program is suitable for "normal" driving which provides earlier up shifts and lock-up. In addition the transmission oil pressure is adjusted to provide smooth gear engagement.

Sport mode

The transmission switches from economy mode to sport mode if the accelerator pedal (AP) is pressed down quickly. The conditions are that the throttle opens and the vehicle speed exceeds 50 km/h. As soon as the accelerator pedal (AP) is moved less quickly economy mode is resumed. In the sport mode shifting program the shifting points are adjusted to provide the best possible performance. Down shifting occurs at lower engine speed (RPM).

Extreme mode

At wide open throttle (WOT) the kick-down function is engaged and the transmission shifts to the lowest possible gear. In this way a boost of power is achieved when overtaking for example.

Winter mode

Winter mode is selected using the (W) button on the top panel of the gear selector assembly. Winter mode enables starting off in a high gear to prevent the wheels from spinning on a slippery surface. This mode can also be used in other difficult situations in which the driver needs more direct control over gear selection. Depending on the gear position, the following combinations can be obtained:

- **D** The car starts in 3rd gear. Automatic shifting between 3rd, 4th and 5th gears
- **4** The car starts in 3rd gear. Automatic shifting between 3rd and 4th gears occurs earlier than in economy mode, D position. 5th gear is locked out
- **3** The car starts in 3rd gear. There is no upshifting or downshifting
- **L** The car starts in 2nd gear. There is no upshifting or downshifting.

The warning lamp on the dashboard lights when winter mode is selected.

If kick-down is activated in Winter mode, the transmission uses all gears for maximum performance.

OTHER MODES

Adaptation

The transmission control module (TCM) monitors each shift during all driving conditions to fulfill optimal and smooth shifting. This is carried out by the control module either lowering or increasing the hydraulic line pressure used during the shift itself. The changed pressure levels are stored in the control module memory when the car has been switched off and are retrieved on start-up. This provides improved shifting comfort and

increased service life.

Adaptation occurs when the following conditions have been met:

- Throttle opening is steady
- Oil temperature between 65° C and 110° C.

Catalytic converter start

Shifting occurs differently during engine warm up. This function is used to help the engine reach its operating temperature by preventing torque converter lock-up and by delaying up shifts. This function works in the D-position but not in the winter mode (W). Because of this function, it is normal for the 1-2 and 2-3 shift to be noticeably delayed when the car engine is cold. This is a normal consequence of this function.

Temperature controlled lock-up

If the transmission temperature increases abnormally as a result of heavy load under high ambient temperature conditions, the torque converter lock-up function is activated as often as possible (temperature controlled lock-up). This reduces slippage and the generation of heat in the transmission. If the temperature drops below +20° C the lock-up function will not be used.

Slipping lock-up

The slipping lock-up function provides smoother engagement with reduced vibration and decreased noise when a gear is engaged. In this mode, the torque converter clutch is engaged, but not fully locked.

The following must be met in order for the function to activate:

- Gear selector in position D, 4 or 3
- Gear 3, 4 or 5
- The transmission input speed is 1100 rpm or more and the throttle opening is 35 % or less
- The transmission oil temperature is 40 - 120°C.

Due to the torque converter slipping between 50-200 rpm, the friction properties of the transmission fluid are very important. The transmission fluid differs from conventional ATF oil properties. Always use the specified fluid for this transmission. Failure to do so may compromise the function and set a diagnostic trouble code (DTC).

The engine coolant must reach a certain temperature before the function engages.

Driving uphill

The transmission control module (TCM) may change the gear shift pattern slightly when driving uphill. This is to avoid busy shifting.

Neutral control (only available on certain models)

This function is activated when the driver stops the car and the car is stationary, at traffic lights for example. The transmission control module (TCM) then disengages the C1 clutch which releases the forward drive of the transmission and reduces the load on the engine. The function improves fuel consumption and reduces vibrations at idle speed. When the driver releases the brake, the C1 clutch engages and drive is resumed.

The following conditions must be met for the Neutral control function to be activated:

- Gear selector in position D, 4, or 3 when Winter mode and Geartronic are not selected
- Oil temperature above + 10° C
- Throttle position < 3 %
- Brake pedal depressed
- Speed 0 km/h
- Engine speed < 1500 rpm.

There are two time factors for engagement: There is a 2 second delay in position D when stationary and a 5 second delay at N to D.

SHIFTING USING GEARTRONIC

Fig. 192: Checking Shift Positions
Courtesy of VOLVO CARS CORPORATION

When the gear selector is moved to the Geartronic position (MAN) the automatic transmission remains in

hydraulic position D, but when the gear selector is moved upwards (+) the gear selector module (GSM) transmits a signal to the transmission control module (TCM) to shift up. When the gear selector is moved downwards (-) a signal is transmitted to the transmission control module (TCM) to shift down. The driver information module (DIM) switches the symbol in the combined instrument panel from D to the current gear, for example 3, when the gear selector is in the MAN position. A signal is sent to the gear selector module (GSM) to light the M LED and switches off the other LEDs. The transmission control module (TCM) determines if shifting can be carried out and the driver information module (DIM) indicates the current gear. If shifting is permitted the solenoids are activated according to each specific gear pattern.

However, in certain situations the transmission control module (TCM) assumes the shifting decision. The following applies:

- When stationary only 1st, 2nd and 3rd gears can be selected. 4th gear can be selected at speeds in excess 30 km/h and 5th at speeds in excess of 40 km/h
- Automatic down shifting occurs below a certain speed. Example: 2nd gear is selected. Automatic down shifting occurs when shifting from 2nd gear to 1st at 2 km/h if the speed, before then, exceeds 25 km/h. in other cases 2nd gear is retained. For example, when 3rd gear is engaged despite the car being stationary
- Manual up shifting is required after automatic down shifting. Kick-down is not available in the Geartronic-position (MAN)
- The permitted speed for manual down shifting corresponds to those for kick-down downshifting, i. e. engine speed at approximately 6 000 rpm
- If the transmission temperature becomes too high the transmission control module (TCM) determines the shift position. The purpose is to maintain a gear where lock-up is possible at the current speed
- Lock-up is possible in 3rd, 4th and 5th gears. (1st and 2nd gears do not have lock-up).

Other

In position MAN the lever position signal to the gear selector module (GSM) is generated as follows:

For each of the three gear selector positions a hall sensor is mounted on the printed circuit board for the gear selector control module (GSM). A permanent magnet on the lever affects the output signals from the sensors to the control module. The control module can read off the position of the lever through the differences in the signal characteristics.

SHIFT-LOCK

Fig. 193: Identifying Shift-Lock
Courtesy of VOLVO CARS CORPORATION

To avoid any chance of the gear selector inadvertently moving from the P position, the car is also equipped with an electrically operated shift-lock function. This locks the interlock pin in the gear selector lever in the shift-lock section, locking the selector lever in the P position. To move the gear selector from the P position, the ignition must be switched on and the brake pedal depressed. (The stop lamp switch is activated.). The central electronic module (CEM) reads the position of the brake pedal via direct connection to the brake pedal sensor and transmits a signal to the gear selector control module (GSM) to deactivate the solenoid in the gear lever selector. The solenoid lock pin is pushed in and the gear selector lock button can be pressed down as usual to select another gear. When the ignition is in position "0", the solenoid is deactivated. In this position the shifter is mechanically locked by the key lock cable.

IGNITION SWITCH INTERLOCK

Fig. 194: Identifying Ignition Switch Interlock
Courtesy of VOLVO CARS CORPORATION

An interlock and security feature (ignition switch interlock) is mechanically connected to the ignition switch by a cable. The ignition switch interlock is controlled by the position of the lock cylinder in the ignition switch and by the position of the gear selector. This means that the gear selector must be in the P-position for the ignition key to be removed from the ignition switch. The ignition key must be turned to position I or II before the lever can be moved from the P-position. The ignition switch interlock is used only in combination with shift-lock.

PARK / NEUTRAL POSITION (PNP) FUNCTION

The gear-shift position sensor has a park / neutral position (PNP) function to prevent the engine being started with a gear selected.

This function prevents the engine being started unless the P or N positions are selected. This prevents the car from lurching forwards when started.

ADAPTATION DATA

There are two functions for adaptation in the transmission control module (TCM) software which can be activated:

- Resetting adaptation - carried out after replacing internal components or the entire transmission
  - the transmission control system
  - the transmission fluid
  - the entire transmission
  - the transmission control module (TCM).
- Adaptation function - This function helps the mechanic to adapt the transmission. It makes it easier to reset the function of the transmission after repair or replacement of, for example:
  - the transmission control system
  - the transmission fluid
  - the entire transmission
  - the transmission control module (TCM).

When the adaptation function has been activated, the test drive instructions must be followed. The following shifts can be adapted:

- 1-2
- 2-3
- 3-4
- 4-5
- N-D
- 5-4
- 4-3
- 3-2
- 2-1
- N-R
- Neutral Control engagement and disengagement, if equipped.

While the car is in this mode, the orange/yellow warning lamp in the center of the combined instrument panel is used to indicate when each shift has been adapted to its target value.

When the orange/yellow warning lamp (triangle) flashes after each of the listed shifts, the adaptation is complete.

NOTE: The function is only available in certain software versions.

Adaptation of the transmission is activated via the VIDA vehicle communication socket.

COUNTER FOR TRANSMISSION FLUID DATA

Fig. 195: Draining Oil
Courtesy of VOLVO CARS CORPORATION

A counter for transmission oil quality is built into the software for the transmission control module (TCM). The counter counts up the amount of time the oil is above a certain temperature. When the counter has reached the maximum value, the diagnostic trouble code (DTC) for an oil change is stored in the control module. When replacing transmission fluid the counter must be reset to prevent a diagnostic trouble code (DTC) being stored incorrectly. This applies when the transmission fluid is changed and when the fluid is changed during a repair.

The reset function is activated via the VIDA vehicle communication socket.

EMERGENCY MODE IN THE EVENT OF A FAULT

An emergency program is activated to deal with the fault when the transmission control module (TCM) detects a transmission fault (permanent fault). If the transmission control module (TCM) detects a permanent fault, an emergency mode is activated. The transmission control module (TCM) then implements corrective action to protect the transmission, while leaving the car in the best possible drivable condition. Minor malfunctions do not activate an emergency program. There are different programs depending on the type of fault:

- Emergency mode
- Limp-home mode.

Emergency mode is activated for minor faults and the Limp-home mode for the most serious faults. If the malfunction is intermittent, the transmission control module (TCM) returns to normal operation the next time the ignition is switched on.

Emergency mode

The warning lamp in the combined instrument panel comes on and a or text message is displayed for diagnostic trouble codes (DTCs) stored in the transmission control module (TCM).

The transmission shifts in all gears but transmits no signal to the lock-up solenoid. This means that lock-up is not available.

Limp-home mode

The warning lamp in the combined instrument panel comes on or a text message is displayed for diagnostic trouble codes (DTCs) stored in the transmission control module (TCM).

The transmission control module (TCM) interrupts the activation of all solenoids. This means that no shifting is possible. The transmission operates only in 3rd gear in positions 3 and L, 4th gear in position D and reverse in position R. Shifting can only be carried out manually between 3rd and 4th gear and reverse gear.

No control of line pressure solenoids SLS and SLT. Maximum system pressure constantly which results in harsh upshifting and downshifting and harsher shifts when engaging P-R, N-R and N-D.

SYSTEM OVERVIEW
