Remove from under the dashboard:

- the retaining clip for the push rod for the power brake booster
- the four nuts securing the power brake booster to the firewall.

Remove from the engine compartment:

- the connectors
- the vacuum hose
- the power brake booster.

TRANSFERRING COMPONENTS

Transfer:

- the pedal position sensor. See: **PEDAL POSITION SENSOR, REPLACING**
- the check valve
- the terminal for the check valve.

INSTALLATION

INSTALLING THE POWER BRAKE BOOSTER

NOTE: For tightening torques, see: TIGHTENING TORQUE .

Install in the engine compartment:

- the connectors
- the vacuum hose
- the power brake booster.

Install under the dashboard:

- the 4 x M8 nuts for mounting in the power brake booster
- the retaining clip for the push rod for the power brake booster.

INSTALLING THE SOUNDPROOFING PANEL

Install:

- the soundproofing panel
- the 2 x screws.

INSTALLING THE ABS UNIT

Carefully pull the ABS unit to the installation position.

Install the 3 x M6 screws for mounting in the bracket.

FINISHING

Connect the connector on the cable duct.

Install the master cylinder and bleed the brake system. See: **MASTER CYLINDER, REPLACING**.

INSTALLATION

INSTALLING THE POWER BRAKE BOOSTER

NOTE: For tightening torques, see: TIGHTENING TORQUE .

Install in the engine compartment:

- the connectors
- the vacuum hose
- the power brake booster
- lifting eye
- central electrical unit.

Install under the dashboard:

- the 4 M8 nuts used to secure the power brake booster
- the retaining clip for the push rod for the power brake booster

INSTALLING THE SOUNDPROOFING PANEL

Install:

- the soundproofing panel
- the 2 screws.

INSTALLING THE ABS UNIT

Carefully pull the ABS unit to the installation position.

Install the 3 M6 screws for the mounting bracket.

Hydraulic-Vacuum-Hydraulic Brakes - Symptom Verification

INFORMATION AND VERIFICATION, BRAKE PEDAL/PULSATIONS (2006-2012)

BRAKE PEDAL/PULSATIONS

SYMPTOM AND FUNCTION DESCRIPTION

NOTE: The symptom should always be verified together with the customer.

The following tips may be of help to decide if the symptom is due to a product feature or if continued troubleshooting is needed.

HINT: Brake pedal pulses when the vehicle's ABS works.

INFORMATION AND VERIFICATION, BRAKE PEDAL/SPONGY (2006-2012)

BRAKE PEDAL/SPONGY

SYMPTOM AND FUNCTION DESCRIPTION

NOTE: The symptom should always be verified together with the customer.

The following tips may be of help to decide if the symptom is due to a product feature or if continued troubleshooting is needed.

HINT: When the engine is off the brake pedal shall stop dead when pressed down.

HINT: At start the brake pedal can be pressed all the way down with some force.

INFORMATION AND VERIFICATION, BRAKES/BRAKES TOO SENSITIVE (2006-2012)

BRAKES/BRAKES TOO SENSITIVE

SYMPTOM AND FUNCTION DESCRIPTION

NOTE: The symptom should always be verified together with the customer.

The following tips may be of help to decide if the symptom is due to a product feature or if continued troubleshooting is needed.

HINT: Sensitivity of the brake pedal differs between different models.

PARKING BRAKE, ADJUSTING

NOTE: **The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.**

REMOVAL

REMOVING THE PANEL

Fig. 1: Identifying Manual Adjustment For Parking Brake
Courtesy of VOLVO CARS CORPORATION

Remove the panel for the center console on the left-hand side.

Locate the adjustment for the parking brake (1).

Fig. 2: Removing Retaining Clip
Courtesy of VOLVO CARS CORPORATION

Remove the retaining clip.

NOTE: Take care when removing the retaining clip.

Screw the socket clockwise over the groove for the retaining clip. Press the socket back over the adjustment rod.

Fig. 3: Installing Retaining Clip
Courtesy of VOLVO CARS CORPORATION

Screw the socket anticlockwise so that the groove for the clip emerges.

Install the clip.

ADJUSTING THE PARKING BRAKE

Fig. 4: Adjusting Parking Brake
Courtesy of VOLVO CARS CORPORATION

Depress the brake pedal to the first notch. Press out the adjustment using the adjustment rod: see **9512947** .

Test the parking brake.

Full effect can be obtained between the second and fifth ratchet teeth.

INSTALLATION

INSTALLING THE PANEL

Install the panel for the center console on the left-hand side.

PARKING BRAKE SELF-ADJUSTMENT, RESETTING

NOTE: **The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.**

REMOVAL

REMOVING SOUNDPROOFING PANELS

Fig. 5: Identifying Driver Side Soundproofing Panel
Courtesy of VOLVO CARS CORPORATION

HINT: The soundproofing panel sits in grooves at the pedal box.

Slacken off the 2 screws.

Pull the soundproofing panel straight down at the dashboard. Then pull the soundproofing panel backwards. Lift out the soundproofing panel.

REMOVING THE OBDII BRACKET

Remove the 2 screws.

Allow the bracket to hang from the wiring

REMOVING THE RELAY BOX

Fig. 6: Removing Relay Box
Courtesy of VOLVO CARS CORPORATION

Insert a screwdriver between the bracket and the relay box. Turn the screwdriver so that the bracket opens out. At the same time, pull the relay box out of the bracket towards the underside of the dashboard. Lift the relay box off the bracket. Pull the relay box downward under the dashboard.

REMOVING THE PARKING BRAKE PEDAL

Fig. 7: Identifying Bolts, Connector And Cable
Courtesy of VOLVO CARS CORPORATION

Remove:

- the pedal (1) from the body, 3 screws, and pull/turn it diagonally backwards/inwards
- the wiring (2) for the pedal switch
- the disengagement cable (3) for the pedal.

RESET THE PARKING BRAKE TO THE ZERO POSITION

Fig. 8: Resetting Parking Brake
Courtesy of VOLVO CARS CORPORATION

Install a hose with an inner diameter of **5 mm** on the end of the friction spring (1).

Open the friction spring so that the primary cable runs freely. Use a pipe wrench to push back the primary cable mounting (2).

Insert a **6.5 mm** locking pin into the hole in the pedal (3) (it must pass through the bracket, cable pulley, pedal and the other bracket).

INSTALLATION

NOTE: For tightening torques, see: TIGHTENING TORQUE .

RESETTING THE PARKING BRAKE

Fig. 9: Resetting Parking Brake
Courtesy of VOLVO CARS CORPORATION

Press the primary cable mounting (2) back into place.

Remove the locking pin (3). Reset the primary cable mounting to the operating position.

Remove the hose from the friction spring (1).

INSTALLING THE PARKING BRAKE PEDAL

Install:

- the disconnecting cable for the pedal
- the cables for the switch before the pedal has been turned in
- the parking brake pedal, 3 screws (M8).

FINISHING

Check the function of the parking brake.

Press down and release the pedal 5 times.

NOTE: Only when replacing.

Press the pedal down so that the clip cracks

INSTALLING THE RELAY BOX IN THE PASSENGER COMPARTMENT

Install the relay box on the bracket.

Press the relay box forward so that the catches engage in the bracket and "click". Install the soundproofing panel using 2 screws.

INSTALLING THE OBDII BRACKET AND SOUNDPROOFING PANEL

Install:

- the OBDII bracket using the 2 screws
- the soundproofing panel using the 2 screws.

PREPARATORY WORK

RESETTING THE PARKING BRAKE

Fig. 1: Identifying Manual Adjustment For Parking Brake
Courtesy of VOLVO CARS CORPORATION

If the vehicle has a **manual** adjustment for the parking brake, see the illustration and no. 1. Reset the parking brake. See: **PARKING BRAKE, ADJUSTING** .

If the vehicle has a **self-adjusting** parking brake. Reassemble and lock the self-adjuster unit for the parking brake. See: **PARKING BRAKE SELF-ADJUSTMENT, RESETTING** .

REMOVAL

REMOVING THE BRAKE CALIPER WITH THE HOLDER AND THE BRAKE DISC

Fig. 2: Brake Disc And Caliper Holder
Courtesy of VOLVO CARS CORPORATION

Remove the mounting screws for the brake caliper. Hang the caliper from the spring. Use a wire so as not to damage the brake pipe.

Remove the screw and the brake disc.

NOTE: Do not damage the ABS line.

REMOVING THE PARKING BRAKE SHOES

Fig. 3: Identifying Brake Shoe Fixing Springs & Tool (999 7225)
Courtesy of VOLVO CARS CORPORATION

Remove the two fixing springs on the brake shoes. Use **9997225** .

Compress the spring and move it backward, and let up so that the spring's end fits the slot in the bracket and can be removed.

Fig. 4: Identifying Return Spring & Brake Shoes
Courtesy of VOLVO CARS CORPORATION

Detach the return spring at the expander.

Bend the brake shoes apart and remove them with the return spring and spacer.

CLEANING AND CHECKING

Fig. 5: Identifying Wheel Hub
Courtesy of VOLVO CARS CORPORATION

Check that no grease has leaked out of the wheel hub.

Check the parking brake expander for damage. Lubricate if necessary.

Clean the surfaces of the brake drum where the brake shoes make contact.

Check that hub flange is clean. Remove any rust.

Lubricate the contact surfaces on the brake shield. Use heat-resistant grease, P/N 116 1325-4.

INSTALLATION

NOTE: For tightening torques, see: TIGHTENING TORQUE .

INSTALLING BRAKE SHOES

Fig. 6: Brake Shoes, Spacer And Small Return Spring
Courtesy of VOLVO CARS CORPORATION

Install:

- the brake shoes
- the spacer and the small return spring on the brake shoes.

Fig. 7: Identifying Brake Shoe Fixing Springs & Tool (999 7225)

Courtesy of VOLVO CARS CORPORATION

Fig. 8: Identifying Springs
Courtesy of VOLVO CARS CORPORATION

Install the fixing springs for the brake shoes and the return spring at the expander.

Install:

- the lower fixing spring, use **9997225** .

  Point the spring's catch forward, compress the spring and move it forward and let up so that the catch locks in the bracket.

- the upper fixing spring.
- the return spring by the expander.

Check that the brake shoes are positioned correctly in the expander.

Install the return spring at the expander.

INSTALLING THE BRAKE DISC AND THE BRAKE CALIPER WITH THE HOLDER

Fig. 9: Brake Disc And Caliper Holder
Courtesy of VOLVO CARS CORPORATION

Install:

- the 1 M6 screw for the disc
- the screws for the caliper holder. Tighten. See **SUMMARY OF SPECIFIC COMPONENTS AND TIGHTENING TORQUES** .

Use new mounting screws.

FINISHING

ADJUSTING THE PARKING BRAKE

Fig. 10: Identifying Manual Adjustment For Parking Brake
Courtesy of VOLVO CARS CORPORATION

If the vehicle has a **manual** adjustment for the parking brake, see the illustration and no. 1. Adjust the parking brake. See: **PARKING BRAKE, ADJUSTING** .

If the vehicle has a **self-adjusting** parking brake. Reset the self adjuster for the parking brake. See: **PARKING BRAKE SELF-ADJUSTMENT, RESETTING** .

Install the wheel. See: **INSTALLING WHEELS** .

BREAKING IN THE NEW PARKING BRAKE PADS AFTER REPLACEMENT

NOTE: Activate the parking brake firmly for 10 minutes.

Break in the parking brake by depressing the parking brake pedal to the third notch. Then drive at 20 km/h for 40 seconds or 250 meters.

With the vehicle stationary, depress the parking brake pedal to the sixth notch. Release the brake pedal without keeping your foot on the pedal.

Post-adjust the parking brake if necessary.

PARKING BRAKE CABLE FRONT, REPLACING (2003, 2004)

REMOVAL

REMOVING THE CENTER CONSOLE

Remove center console. See: **CENTER CONSOLE, REPLACING** .

REMOVING THE BRAKE CABLE IN THE CENTER CONSOLE

Fig. 12: Removing Rear Cables From Equalizer
Courtesy of VOLVO CARS CORPORATION

Remove:

- the rear mechanical cables from the power distributor
- the clips for the mechanical cable casing using long nose pliers. Lift the cable from the bracket.

REMOVING THE SOUNDPROOFING PANEL

Fig. 13: Identifying Driver Side Soundproofing Panel
Courtesy of VOLVO CARS CORPORATION

Remove:

- the 2 x screws
- the soundproofing panel.

REMOVING THE OBDII BRACKET

Remove the 2 screws. Allow the bracket to hang from the wiring.

REMOVING CENTRAL ELECTRONIC MODULE (CEM)

Fig. 14: Identifying Screwdriver, Bracket And Relay Box
Courtesy of VOLVO CARS CORPORATION

Insert a screwdriver between the bracket and the relay box. Turn the screwdriver so that the bracket opens out. At the same time, pull the relay box out of the bracket towards the underside of the dashboard. Lift the relay box off the bracket. Pull the relay box downward under the dashboard.

REMOVING THE PARKING BRAKE PEDAL

Fig. 15: Identifying Bolts, Connector And Cable
Courtesy of VOLVO CARS CORPORATION

Remove:

- the pedal (1) from the bodywork. Slacken off the 3 screws and pull / twist out the pedal diagonally backwards / inwards. Remove the pedal.
- the wiring (2) for the pedal switch

- the disengagement cable (3) for the pedal.

REMOVING THE MECHANICAL CABLE FOR THE PARKING BRAKE PEDAL

Fig. 16: Removing Mechanical Cable
Courtesy of VOLVO CARS CORPORATION

Remove:

- the mechanical cable from the cable pulley in the pedal
- the retaining clip
- the outer casing for the mechanical cable from the pedal using round-nose pliers.

INSTALLATION

NOTE: For tightening torques, see: TIGHTENING TORQUE .

INSTALLING THE FRONT BRAKE CABLE

Pull the mechanical cable into the center of the tunnel above the insulation.

NOTE: The cable for the parking brake pedal must be installed before the power distributor at the tunnel.

INSTALLING THE ACCELERATOR PEDAL (AP)

Install:

- the lower screw for the accelerator pedal (AP)
- tighten the 3 M6 screws for the accelerator pedal (AP). The cable must be underneath the mounting plate for the accelerator pedal (AP) so that the 2 pieces of tape on the cable are hidden by the mounting.

INSTALLING THE CABLE FOR THE PARKING BRAKE PEDAL

Fig. 17: Installing Cable Hook
Courtesy of VOLVO CARS CORPORATION

Applies to cars with pedals up to part number 30666703:

NOTE: The wide edge of the spacer washer must face the left side in the vehicle.

Press the mechanical cable into place in the pedal.

Secure the mechanical cable using the retaining clip.

Apply low-temperature grease, P/N 1161427-8, to the end piece of the mechanical cable.

Install the end piece of the mechanical cable in the cable pulley in the pedal.

Fig. 18: Installing Cable Hook
Courtesy of VOLVO CARS CORPORATION

Applies to cars with pedals part number 30714010 or higher:

CAUTION: Remove the plastic spacer washer. Only a steel washer may be used as a spacer to prevent abnormal wear of the primary cable.

Press the mechanical cable into place in the pedal.

Secure the mechanical cable using the retaining clip.

Apply low-temperature grease, P/N 1161427-8, to the end piece of the mechanical cable.

Install the end piece of the mechanical cable in the cable pulley in the pedal.

INSTALLING THE BRAKE CABLE IN THE CENTER CONSOLE

Install:

- the outer casing for the cable in the console
- the power distributor for the front mechanical brake cable in the two rear mechanical brake cables.

INSTALLING THE PARKING BRAKE PEDAL

Install:

- the disengagement cable for the pedal
- the wiring for the switch before the pedal has been turned in
- the parking brake pedal using the 3 x M8 screws.

INSTALLING THE RELAY BOX IN THE PASSENGER COMPARTMENT

Install the relay box on the bracket.

Press the relay box forward so that the catches engage in the bracket and a "click" is heard.

INSTALLING THE OBDII BRACKET

Install:

- the OBDII bracket
- the 2 screws.

INSTALLING THE SOUNDPROOFING PANEL

Install:

- the soundproofing panel
- the 2 x screws

FINISHING

Adjust the parking brake. See: **PARKING BRAKE, ADJUSTING** .

NOTE: Activate the parking brake firmly for 10 minutes.

POST-ADJUSTING THE PARKING BRAKE

Post-adjust the parking brake if necessary.

REMOVAL

REMOVING THE CENTER CONSOLE

Remove the center console. See **CENTER CONSOLE, REPLACING** .

REMOVING THE BRAKE CABLE

Fig. 28: Securing A Wire In The Cable Eyelet.
Courtesy of VOLVO CARS CORPORATION

Remove the mechanical cable from its segment.

Take hold of the mechanical cable and bend it to the side so that it can be removed.

Secure a heavy wire to the end of the mechanical cable.

Bend a thick metal wire (welding rod) as illustrated.

Secure the wire in the cable eyelet. Bend the wire over the eyelet.

Fig. 29: Removing/Installing Heat Deflector Plate
Courtesy of VOLVO CARS CORPORATION

Raise the car.

Slacken off both screws for the heat shield on both sides.

Fold the heat deflector plate down.

Remove the rubber grommet for the mechanical cable.

REMOVING THE BRAKE CALIPER WITH THE HOLDER AND THE BRAKE DISC

Fig. 30: Brake Disc And Caliper Holder
Courtesy of VOLVO CARS CORPORATION

Remove the mounting screws for the brake caliper. Hang the caliper from the spring. Use a wire so as not to damage the brake pipe.

Remove the screw and the brake disc.

NOTE: Do not damage the ABS line.

REMOVING THE EXPANDER

Fig. 31: Identifying Return Spring And Expander
Courtesy of VOLVO CARS CORPORATION

Remove:

- the return spring at the expander
- the expander. Lift the brake shoe slightly. Grip the expander and pull it outwards to access the cable.

Unhook or pry apart the expander (1) by the mechanical cable to remove it.

REMOVING THE BRAKE CABLE, CONTINUED

Fig. 32: Applying Screwdriver Between Guide Sleeve Lug And Wheel Arch

Remove the clamp (1) by the tie rod.

Remove the mechanical cable from its mountings (2).

Pull the mechanical cable from the floor until the welding rod is visible (3).

Remove the mechanical cable from the welding rod.

INSTALLATION

NOTE: For tightening torques, see: TIGHTENING TORQUE .

INSTALLING THE MECHANICAL CABLE IN THE WHEEL UNIT

Fig. 34: Installing Brake Cable
Courtesy of VOLVO CARS CORPORATION

Lubricate the O-ring on the wheel unit lightly using petroleum jelly.

Install and press the guide lug for the cable sleeve into place in the wheel unit.

NOTE: This is important for the operation of the parking brake.

INSTALLING THE EXPANDER ON THE CABLE

Fig. 35: Identifying Expander Installed On Mechanical Cable
Courtesy of VOLVO CARS CORPORATION

Install:

- the expander on the cable. Press the mounting together to lock the cable in the expander
- the expander between the brake shoes
- the return spring.

Check the function.

INSTALLING THE MECHANICAL CABLE

Fig. 36: Identifying Brake Cable & Clamps
Courtesy of VOLVO CARS CORPORATION

Secure the cable in its clamps and on the welding rod.

Bend the welding rod over the end of the cable.

Install the cable in the hole in the floor.

Press the rubber grommet into the hole in the floor.

Press the mechanical cable into place in its mounting between the heat shield and the fuel tank.

Also press the mechanical cable between the fuel tank and the edge of the heat deflector.

Lower the vehicle.

Take hold of the welding rod. Pull the mechanical cable with the sleeve through the bodywork and up to the parking brake lever.

Remove the welding rod.

Install the cable end in the segment.

Install:

- the 1 M6 screw for the disc
- the screws for the caliper holder. Tighten. See **TIGHTENING TORQUE** .

Use new mounting screws.

FINISHING

If the car has manual adjustment to the parking brake, see the illustration and (1). Adjust the parking brake. See: **PARKING BRAKE, ADJUSTING** .

If the car has a self-adjusting parking brake. Reset the self adjuster for the parking brake. See: **PARKING BRAKE SELF-ADJUSTMENT, RESETTING** .

NOTE: Activate the parking brake firmly for 10 minutes.

Install:

- the center console. See **CENTER CONSOLE, REPLACING**

- the wheel. See **INSTALLING WHEELS** .

ONLY WITH MANUAL ADJUSTMENT OF THE PARKING BRAKE

Post-adjust the parking brake if necessary.

Remove:

- the 2 x screws
- the soundproofing panel.

REMOVING THE OBDII BRACKET

Remove the 2 screws. Allow the bracket to hang in the cable harness.

REMOVING THE RELAY BOX

Fig. 42: Removing Relay Box
Courtesy of VOLVO CARS CORPORATION

Insert a screwdriver between the bracket and the relay box. Turn the screwdriver so that the bracket opens out. At the same time, pull the relay box out of the bracket towards the underside of the dashboard. Lift the relay box off the bracket. Pull the relay box downward under the dashboard.

REMOVING THE PARKING BRAKE PEDAL

Fig. 43: Identifying Bolts, Connector And Cable
Courtesy of VOLVO CARS CORPORATION

Remove:

- the pedal (1) from the bodywork. Slacken off the 3 screws and pull / twist out the pedal diagonally backwards / inwards. Remove the pedal
- the cable harness (2) for the pedal switch

- the disengagement cable (3) for the pedal.

REMOVING THE MECHANICAL CABLE FOR THE PARKING BRAKE PEDAL

Fig. 44: Removing Mechanical Cable
Courtesy of VOLVO CARS CORPORATION

Remove:

- the mechanical cable from the cable pulley in the pedal
- the retaining clip
- the outer casing for the mechanical cable from the pedal using round-nose pliers.

INSTALLATION

NOTE: For tightening torques, see: TIGHTENING TORQUE .

INSTALLING THE CABLE FOR THE PARKING BRAKE PEDAL

Fig. 45: Installing Cable Hook
Courtesy of VOLVO CARS CORPORATION

Applies to cars with pedals up to part number 30666703:

NOTE: The wide edge of the spacer washer must point to the left in the vehicle.

Press the mechanical cable into place in the pedal.

Secure the mechanical cable using the retaining clip.

Apply low-temperature grease, P/N 1161427-8, to the end piece of the mechanical cable.

Install the end piece of the mechanical cable in the cable pulley in the pedal.

Fig. 46: Installing Cable Hook
Courtesy of VOLVO CARS CORPORATION

Applies to cars with pedals part number 30714010 or higher:

CAUTION: Remove the plastic spacer washer. Only a steel washer may be used as a spacer, this prevents abnormal wear of the primary cable.

Press the mechanical cable into place in the pedal.

Secure the cable using the retaining clip. Apply low-temperature grease, P/N 1161427-8, to the end piece of the mechanical cable.

Install the end piece of the mechanical cable in the cable pulley in the pedal.

INSTALLING THE BRAKE CABLE IN THE CENTER CONSOLE

Hook the power distributor for the front brake cable into place in the two rear brake cables.

INSTALLING THE PARKING BRAKE PEDAL

Install:

- the disengagement cable for the pedal
- the cable harness for the switch before the pedal has been turned in
- the parking brake pedal using the 3 x M8 screws.

INSTALLING THE RELAY BOX IN THE PASSENGER COMPARTMENT

Install the relay box on the bracket.

Press the relay box forward so that the catches engage in the bracket and "click".

INSTALLING THE OBDII BRACKET

Install:

- the OBDII bracket
- the 2 screws.

INSTALLING THE SOUNDPROOFING PANEL

Install:

- the soundproofing panel
- the 2 screws.

INSTALLING THE CENTER CONSOLE

Install the centre console. See: **CENTER CONSOLE, REPLACING** .

FINISHING

Adjust the parking brake. See **PARKING BRAKE, ADJUSTING** .

Remove:

- the cable from the cable pulley in the pedal
- the outer casing for the cable from the pedal using round-nose pliers.

INSTALLATION

NOTE: For tightening torques, see TIGHTENING TORQUE .

INSTALLING THE PARKING BRAKE CABLE

Press the cable into place in the pedal.

Install the cylindrical steel end piece for the cable in the cable pulley in the pedal.

Install the parking brake pedal. See **PARKING BRAKE SELF-ADJUSTMENT, RESETTING** .

NOTE: Press the pedal down so that the clip cracks.

INSTALLING THE BRAKE CABLE TO THE CENTER CONSOLE

Hook the power distributor for the front brake cable into place in the two rear brake cables.

INSTALLING THE CENTER CONSOLE

Install the center console. See: **CENTER CONSOLE, REPLACING** .

FINISHING

Install the parking brake pedal. See: **PARKING BRAKE SELF-ADJUSTMENT, RESETTING** .

NOTE: Press the pedal down so that the clip cracks.

- Remove and hang up the engine block heater (if applicable) on the left front mounting for the sub-frame
- Position a lifting table under the sub-frame
- Remove the screws holding the sub-frame brackets to the bodywork on both sides
- Remove the four screws from the sub-frame
- Carefully lower the sub-frame.

NOTE: Ensure that the steering gear screws release from the sub-frame.

Fig. 17: Hanging Steering Gear From Hook So That Lower Steering Shaft Does Not Come Apart

Transfer

- the control arms. Use new screws and new nut. Tighten the front screws. Tighten to **65 Nm** . Angle-tighten **90°** . Use bevel protractor see **9512050** . Tighten the rear screw. Tighten to **105 Nm** . Angle-tighten **90°**
- the anti-roll bar. Tighten to **60 Nm**
- the right-hand engine mounting. Tighten the screws. Tighten to **65 Nm** . Angle-tighten **60°**
- the mounting for the heated oxygen sensor (HO2S) wiring
- the engine pad.

Install new pipe / hose holders.

INSTALLING THE SUB-FRAME

- Position the sub-frame on a lifting table
- Carefully lift the sub-frame
- Locate the control arms on the ball joints and the steering gear on its mountings
- Remove the hook (999 5045) that is holding the steering gear
- Lift the sub-frame up completely

- Reinstall the engine block heater (if applicable).

Fig. 19: Identifying Bolts, Washers And Brackets In Sub-Frame
Courtesy of VOLVO CARS CORPORATION

- Install the engine block heater (if applicable) on the left front mounting for the sub-frame
- Install the four screws in the sub-frame together with the sub-frame brackets. Use **new screws** . Lubricate the screws
- First tighten the screws on the left side of the sub-frame. Tighten to **105 Nm** . Angle tighten to **120°** . Then tighten the right-hand side to the same value
- Finally tighten the screws for the brackets on both sides to **50 Nm** .

ANTI-LOCK/TRACTION CONTROL

CONNECTING THE BREAKOUT BOX, BRAKE CONTROL MODULE (BCM)

Special tools:

see **9511428**

see **9512958**

CONNECTING THE BREAKOUT BOX

Fig. 1: Identifying Catch & Connector
Courtesy of VOLVO CARS CORPORATION

- Ignition off
- Expose the brake control module. See **BRAKE CONTROL MODULE (BCM), REPLACING**
- Disconnect the control module by pressing in the catch on top of the connector and **carefully** work the cover up so that the connector lifts.

CAUTION: Do not bend the cover up by more than 90°.

- Check in particular that the male and female terminals on the control module and the control module connector are intact, secure and cannot be pressed in. Check that the female terminal cables are securely connected
- In particular, check the terminal pins relevant to the diagnostic trouble code (DTC) / symptom. See **SIGNAL SPECIFICATION, BRAKE CONTROL MODULE (BCM) WITH STC/ TRACS** **or** see **SIGNAL SPECIFICATION, BRAKE CONTROL MODULE (BCM) WITH DSTC (DYNAMIC STABILITY AND TRACTION CONTROL)**
- Connect adapter see **9512958** to the control module's connector (wiring side) and connect breakout box see **9511428** to the adapter.
- The breakout box is designed to facilitate reading off the control module input and output signals when the control module is connected; and the resistance of the cable and component when the control module is disconnected. The use of a breakout box reduces the risk of accidental short-circuits and damage to the connector pins.

BRAKE CONTROL MODULE (BCM), REPLACING

REMOVAL

PREPARATION

NOTE: **In week 35 year 2001 a new brake control module (BCM) was introduced along with a new sensor in the brake electronics.**

Fig. 1: ABS Control Module
Courtesy of VOLVO CARS CORPORATION

Remove the battery cable. See **BATTERY, DISCONNECTING** .

REMOVING THE AIR CLEANER (ACL) HOUSING

Remove the air cleaner (ACL) housing. See **BRAKE PIPE MASTER CYLINDER/ABS UNIT, REPLACING** .

REMOVING THE INTEGRATED RELAY / FUSEBOX

Remove the integrated relay / fusebox. Remove the connector for the ABS unit. See **REMOVING THE INTEGRATED RELAY / FUSEBOX** .

Remove the screw on the bracket.

Lift the box out of the bracket and put it to one side.

DISCONNECTING THE CONNECTOR

Fig. 2: Identifying Catch & Connector
Courtesy of VOLVO CARS CORPORATION

Disconnect the connector from the control module.

Press the catch and pull up the connector. Pull the connector up a maximum of **90** ° (any more and the connector will break).

Pull the connector up from the control module.

REMOVING THE CONTROL MODULE

Fig. 3: Brake Control Module And Screws
Courtesy of VOLVO CARS CORPORATION

- Remove the screws.

  Use a 6 mm Torx external socket

- Carefully pull the control module down so that the terminal pin on the control module comes loose inside the ABS modulator
- Continue pulling the control module down towards the brake lines and lift it out.

CHECKING THE NEW CONTROL MODULE

Fig. 4: ABS Control Module
Courtesy of VOLVO CARS CORPORATION

Check:

- the control module is correct (compare to the old one)
- that none of the pins on the connector are damaged
- that there are no contaminants on the mating surfaces between the control module and the ABS hydraulic modulator
- that no parts of the old control module seals remain on the old ABS hydraulic modulator valves.

INSTALLATION

INSTALLING THE CONTROL MODULE

Fig. 5: Identifying Brake Control Module
Courtesy of VOLVO CARS CORPORATION

Position the control module on the brake lines.

Center the control module with the ABS modulator valves so that the terminal pins are correctly positioned in the modulator.

Press the control module up so that the terminal pins connect.

Install:

- the screws.

  Tighten to **1.8 Nm**

- the connector on the control module. Lock the connector
- the integrated relay/fusebox and the connector for the ABS unit. See **INTEGRATED RELAY / FUSEBOX, INSTALLING**
- the integrated relay / fusebox.

  Tighten the screw. Tighten to **10 Nm**

- the air cleaner (ACL) housing. See **AIR CLEANER (ACL) HOUSING, INSTALLING** .

INSTALLING THE BATTERY LEAD

Install the battery cable. See **BATTERY, DISCONNECTING** .

LOADING SOFTWARE

NOTE: Switch on the ignition. Order software.

VISUAL CHECK

Fig. 6: Identifying Warning Light
Courtesy of VOLVO CARS CORPORATION

Turn on the ignition.

Wait five seconds and until the symbol for the brakes on the dashboard has gone out.

In the event of a fault (the symbol is lit).

Check that the connector is connected.

FUNCTION TEST

WARNING: No ABS, stability and traction control functions are available when there is communication with the Brake control module (BCM) (Volvo Diagnostics are activated). ABS warning lamp flashes for as long as the diagnostics are activated. To cancel the diagnostics before test driving the vehicle, the ignition must be switched off

See: **FUNCTION TEST** .

Use VIDA (Volvo scan tool) to calibrate the control module.

BRAKE FLUID RESERVOIR, REPLACING

REMOVAL

PREPARATIONS

Fig. 7: Identifying Pedal Secured In Depressed Position Using Pedal Jack
Courtesy of VOLVO CARS CORPORATION

Switch off the ignition.

Clean around filler cap at the connector between the reservoir and master cylinder and at any hose connector. This is to ensure that no contaminants enter the brake system.

Place paper under the master cylinder. This is to protect the paintwork from damage if brake fluid is spilled.

Secure the pedal in the depressed position. Use a pedal jack.

REMOVE THE UPPER ENGINE STABILIZER BRACE

Fig. 8: Identifying Engine Stabilizer Brace And Mounting Screws
Courtesy of VOLVO CARS CORPORATION

Remove:

- the mounting screws for the torque rod
- the screw and nut for the engine mounting and torque rod
- the screw for the oil hose clamp
- the engine stabilizer brace.

PREPARATIONS FOR REMOVING THE BRAKE FLUID RESERVOIR

Fig. 9: Hose To Clutch Cylinder

Block the hose to the clutch cylinder. **Applies to cars with manual transmissions** .

Remove the plastic cap and the cable holder

See **REMOVE THE PLASTIC CAP AND THE CABLE HOLDER**

Pull out the master cylinder

Remove the connector from the brake fluid level sensor.

Remove the mounting nuts from the master cylinder.

Pull out the cylinder slightly.

REMOVE THE BRAKE FLUID RESERVOIR

Fig. 10: Brake Fluid Reservoir From Master Cylinder
Courtesy of VOLVO CARS CORPORATION

Remove:

- the screw on the side of the brake fluid reservoir
- the brake fluid reservoir from the master cylinder. Pull the reservoir straight up
- the hose for the clutch cylinder. Applies to cars with manual transmissions.

CLEANING AND CHECKING

Fig. 11: Checking Brake Fluid Reservoir, Level Switch, Check Valves And Seals
Courtesy of VOLVO CARS CORPORATION

Check the brake fluid reservoir, the level switch, the check valves and seals.

Replace the seals if necessary.

Carefully clean the components that were not replaced. Clean off all contaminants and old brake fluid. Use new brake fluid.

INSTALLATION

INSTALL THE BRAKE FLUID RESERVOIR

Fig. 12: Brake Fluid Reservoir From Master Cylinder
Courtesy of VOLVO CARS CORPORATION

Check that all connections are free of contaminants.

Lubricate the O-rings and any hoses with brake fluid or glycerin.

NOTE: **Do not use a soap solution or mineral oil to lubricate the hoses. Use brake fluid or glycerin.**

Install:

- the hose for the clutch cylinder. Remove the hose clip
- the brake fluid reservoir from directly above
- the screw on side of the brake fluid reservoir. Tighten to **3.5 Nm** .

INSTALL THE MASTER CYLINDER

Fig. 13: Hose To Clutch Cylinder
Courtesy of VOLVO CARS CORPORATION

Tighten the mounting nuts. Tighten to **25 Nm** .

Connect the connector on the brake fluid reservoir.

Install the nut for the positive cable. Fold back the positive cable. Tighten the nut at the wheel arch. Tighten to **25 Nm** .

INSTALL THE UPPER TORQUE ROD

Fig. 14: Identifying Engine Stabilizer Brace And Mounting Screws
Courtesy of VOLVO CARS CORPORATION

Install:

- the engine stabilizer brace. Tighten the mounting screws. Tighten to **50 Nm**
- the screw and a new nut for the engine mounting. Tighten to **80 Nm**
- the screw for the oil hose clamp.

FINISHING WORK

Fig. 15: Bleeding Brake System
Courtesy of VOLVO CARS CORPORATION

Fill the brake fluid reservoir with new brake fluid. Use Volvo Genuine parts, DOT 4+.

Remove the pedal jack.

Cars with manual transmissions: Bleed the clutch

If necessary:

Bleed the brake system. See **BRAKE SYSTEM, BLEEDING (USING BLEEDING UNIT)**

Bleed the system again if the pedal travel is more than 40 mm.

Check for leakage.

The brake fluid level must not be above the maximum mark.

Slacken off the brake hose (4) half a turn.

Remove:

- the securing spring (3) carefully so that it does not deform
- the protective caps (1) from the two locating pins (2)
- the locating pins, use a hex socket 7 mm.

REMOVE THE BRAKE CALIPER AND BRAKE PADS

Fig. 4: Identifying Brake Caliper And Brake Pads
Courtesy of VOLVO CARS CORPORATION

Remove:

- the brake caliper from the holder
- the brake hose from the caliper
- the brake pads.

Drain any remaining brake fluid.

NOTE: Do not depress the brake pedal while the brake pads are removed.

SAFETY INFORMATION, BRAKE SYSTEM

WARNING: Brake fluid contains polyglycol ethers and polyglycols.

WARNING: Avoid contact with the eyes.

If the brake fluid comes into contact with the eyes, rinse the eyes with cold running water for 15 minutes. Seek medical attention if the irritation

persists.

Wash your hands thoroughly after handling.

WARNING: **If swallowed, drink water and induce vomiting.**

Seek medical attention immediately.

CAUTION: **If the brake fluid is spilled on a painted surface, the surface must be washed with cold water immediately.**

CLEANING AND CHECKING

Fig. 11: Checking Brake Fluid Reservoir, Level Switch, Check Valves And Seals
Courtesy of VOLVO CARS CORPORATION

Check the brake fluid reservoir, the level switch, the check valves and seals.

Replace the seals if necessary.

Carefully clean the components that were not replaced. Clean off all contaminants and old brake fluid. Use new brake fluid.

INSTALLATION

INSTALL THE BRAKE FLUID RESERVOIR

Fig. 12: Brake Fluid Reservoir From Master Cylinder
Courtesy of VOLVO CARS CORPORATION

Check that all connections are free of contaminants.

Lubricate the O-rings and any hoses with brake fluid or glycerin.

NOTE: **Do not use a soap solution or mineral oil to lubricate the hoses. Use brake fluid or glycerin.**

Install:

- the hose for the clutch cylinder. Remove the hose clip
- the brake fluid reservoir from directly above
- the screw on side of the brake fluid reservoir. Tighten to **3.5 Nm** .

INSTALL THE MASTER CYLINDER

Fig. 13: Hose To Clutch Cylinder
Courtesy of VOLVO CARS CORPORATION

Tighten the mounting nuts. Tighten to **25 Nm** .

Connect the connector on the brake fluid reservoir.

Install the nut for the positive cable. Fold back the positive cable. Tighten the nut at the wheel arch. Tighten to **25 Nm** .

INSTALL THE UPPER TORQUE ROD

Fig. 14: Identifying Engine Stabilizer Brace And Mounting Screws

Install:

- the engine stabilizer brace. Tighten the mounting screws. Tighten to **50 Nm**
- the screw and a new nut for the engine mounting. Tighten to **80 Nm**
- the screw for the oil hose clamp.

FINISHING WORK

Fig. 15: Bleeding Brake System
Courtesy of VOLVO CARS CORPORATION

Fill the brake fluid reservoir with new brake fluid. Use Volvo Genuine parts, DOT 4+.

Remove the pedal jack.

Cars with manual transmissions: Bleed the clutch

If necessary:

Bleed the brake system. See **BRAKE SYSTEM, BLEEDING (USING BLEEDING UNIT)**

Bleed the system again if the pedal travel is more than 40 mm.

Check for leakage.

The brake fluid level must not be above the maximum mark.

Clean the components in denatured alcohol.

Check the components for wear, damage, cracks and rust. Replace components if necessary.

Remove the sealing ring. Use weatherstrip tool see **9814071** or similar so as not to damage the edges of the groove.

Remove the rubber sleeves.

Check the rubber sleeves of the locating pins. Replace if necessary.

Always replace the sealing ring and dust boot when installing. Take particular care to clean the ducts and the grooves for the O-ring and dust boot.

If the cylinder is badly marked, scratched etc., replace the complete caliper.

Remove minor rust deposits using fine sandpaper.

Check the bleed nipple, replace as necessary.

INSTALL THE PISTON IN THE BRAKE CALIPER

Blow the ducts clean using compressed air.

Apply a thin layer of new brake fluid to the cylinders, the piston and the new sealing ring.

Install:

- the piston in the caliper. Carefully press the piston to the bottom
- the dust boot in the groove on the piston. Check that everything is positioned correctly
- the rubber sleeves in the caliper for the locating pins.

INSTALL THE BRAKE CALIPER

Lubricate the locating pins (2) using grease. P/N 1161325-4.

Insert the locating pins into the rubber sleeves. The pins should slide into the sleeves easily.

Secure the brake hose (4) loosely in the caliper.

Install:

- a brake pad in the piston
- the other pad in the caliper holder
- the brake caliper. Tighten the locating pins to **30 Nm**
- the securing springs (3)
- the protective caps (1).

Tighten the brake hose. Tighten to **16 Nm** .

BRAKE SYSTEM BLEEDING

BRAKE SYSTEM BLEEDING

NOTE: Bleeding an ABS brake system takes longer than bleeding a normal brake system.

GUIDELINES FOR BLEEDING

Fig. 1: Brake Fluid And Reservoir
Courtesy of VOLVO CARS CORPORATION

When reconditioning or replacing brake callipers bleed the relevant brake pipe as follows.

The brake pedal must be depressed throughout the operation. This is so that the brake system is not drained of brake fluid.

If the braking system has been completely or partly drained, bleed the whole system.

NOTE: **Use only genuine Volvo brake fluid with designation Volvo DOT 4+. Never reuse brake fluid. Always keep brake fluid in original packaging and well sealed.**

PREPARATIONS

Fig. 2: Brake Fluid Reservoir And Brake Fluid Collection Bottle
Courtesy of VOLVO CARS CORPORATION

Switch off the ignition.

Clean around the brake fluid reservoir filler cap.

Take out the container.

Remove the filler cap.

Fill the brake fluid reservoir completely.

Raise the car

BLEED LEFT FRONT WHEEL

Fig. 3: Identifying Wheel Bleeding Procedure
Courtesy of VOLVO CARS CORPORATION

NOTE: While bleeding, check that there is sufficient brake fluid in the reservoir. Top up if necessary.

Remove the protective cap from the bleed nipple. Connect the hose from the collection bottle.

Depress the brake pedal a few times. Maintain pressure.

Open the bleed nipple.

Depress the pedal fully. Keep it fully depressed for approximately 5 seconds. Release it again. Repeat this 3-5 times until there are no air bubbles in the fluid coming out of the hose.

Tighten the bleed nipple.

Remove the hose from the bleed nipple. Install the protective cap.

Continue bleeding the other wheels in the same way in the following order:

Right front wheel, left rear wheel and right rear wheel.

Checking for air in the brake system and for brake fluid leakage

BRAKE SYSTEM, BLEEDING (USING BLEEDING UNIT)

NOTE: Bleeding an ABS brake system takes longer than bleeding a normal brake system.

GUIDELINES FOR BLEEDING

Fig. 4: Brake Fluid And Reservoir
Courtesy of VOLVO CARS CORPORATION

When reconditioning or replacing brake calipers bleed the relevant brake pipe as follows.

The brake pedal must be depressed throughout the operation. This is so that the brake system is not drained of brake fluid.

If the braking system has been completely or partly drained, bleed the whole system. A bleeding unit that can pressurize the brake system to 0.2-0.3 Mpa must be used.

NOTE: Use only Volvo Genuine Parts brake fluid (Volvo DOT 4+). Never reuse brake

fluid. Always keep brake fluid well sealed in its original packaging.

PREPARATIONS

Fig. 5: Brake Fluid Reservoir And Brake Fluid Collection Bottle

Remove the protective cap from the bleed nipple. Connect the hose from the collection bottle.

Open the bleed nipple. Close it when there are no more air bubbles in the fluid coming out of the hose.

Tighten the bleed nipple.

Remove the hose from the bleed nipple. Reinstall the protective cap.

Bleeding other wheels

Continue to bleed the other wheels as for the left front wheel

Check for leakage from the bleed nipples.

NOTE: **If the dust boot is damaged, dirt may have penetrated into the cylinder. If this is the case, the caliper must be replaced.**

CHECKING THE BRAKE DISC

Fig. 11: Checking Brake Disc
Courtesy of VOLVO CARS CORPORATION

Check brake disc friction surfaces.

If the brake disc displays signs of out-of-true, check its lateral run out. See **BRAKE DISC FRONT, CALIBRATING** .

Replace the brake disc if it displays signs of heavy wear, variable thickness or similar. To replace, see **BRAKE DISC FRONT, REPLACING**.

NOTE: **Minimum disc thickness/replacement limit:**

Brake discs with an outer diameter of 316mm = 25.0 mm. Minimum recommended disc thickness when installing new brake pads = 25.8 mm.

Brake discs with an outer diameter of 336 mm = 27.0 mm. Minimum recommended disc thickness when installing new brake pads = 27.8 mm.

INSTALLATION

NOTE: **For tightening torques, see: TIGHTENING TORQUE .**

BRAKE FLUID (2003-2012)

BRAKE FLUID, REPLACING

GUIDELINES FOR BRAKE FLUID REPLACEMENT

Fig. 13: Brake Fluid And Reservoir
Courtesy of VOLVO CARS CORPORATION

Brake fluid should be changed every two years. If the car is driven in a manner that requires frequent and heavy braking, such as driving in mountainous terrain or in a tropical climate with high humidity, the fluid should be changed every year.

Background

The oil must be replaced because it is hygroscopic (the fluid absorbs water molecules from the air). This absorption of water occurs through the brake hoses and brake fluid reservoir. These components are rubber and plastic respectively and are not completely sealed against water molecules. An increased water content in the brake fluid dramatically reduces its boiling point and causes corrosion in the brake system components. This results in damage to the brake system. Braking performance deteriorates markedly.

NOTE: Use only Volvo Genuine brake fluid (Volvo DOT 4+). Never reuse brake fluid. Always keep brake fluid well sealed in its original packaging.

NOTE: Continually check that there is sufficient brake fluid in the brake fluid reservoir when replacing brake fluid.

PREPARATIONS FOR CHANGING, FRONT

Fig. 14: Collecting Bottle, Hose And G-Clamp
Courtesy of VOLVO CARS CORPORATION

Switch off the ignition.

Clean around the brake fluid reservoir filler cap.

Raise the car.

Take out:

- a collecting bottle and hose to collect brake fluid in
- a G-clamp.

Remove the protective cap from the bleed nipple.

Connect the collecting bottle hose.

CHANGING THE BRAKE FLUID, FRONT

Fig. 15: Bleeding Brake System
Courtesy of VOLVO CARS CORPORATION

Open the bleed nipple, approximately one turn.

Press in the brake caliper piston to the bottom of the caliper. Use G-clamp as illustrated. Leave the G-clamp in

pushed in position.

Press down the brake pedal to the limit position. Keep it pressed down for approximately 2 seconds before releasing it. Repeat this until new brake fluid enters.

Close the bleed nipple when the brake pedal is fully depressed.

Remove:

- the hose. Install the protective cap
- the G-clamp from the brake caliper.

Finishing work, front

See **FINISHING WORK**.

PREPARATIONS FOR REPLACEMENT, REAR

Switch off the ignition.

Clean around the brake fluid reservoir filler cap.

Raise the car

Take out:

- a collecting bottle and hose to collect brake fluid in
- a jimmy
- a large pipe spanner.

REMOVE THE BRAKE CALIPER

See **REMOVE THE RETAINING SPRINGS AND LOCATING PINS FOR THE BRAKE PADS.** .

Press the piston into the brake caliper

See **PRESS THE PISTON INTO THE BRAKE CALIPER**.

INSTALL A JIMMY BAR

Fig. 16: Identifying Jimmy Inserted Between Brake Pads
Courtesy of VOLVO CARS CORPORATION

Insert the jimmy between the brake pads (as a counterhold) to keep the piston in.

REPLACING BRAKE FLUID, REAR

Fig. 17: Bleeding Rear Brakes
Courtesy of VOLVO CARS CORPORATION

Remove the protective cap from the bleed nipple.

Connect the collecting bottle hose.

Press down the brake pedal fully. Keep it pressed down for approximately 2 seconds before releasing it. Repeat this until new brake fluid enters.

Close bleed nipple when the brake pedal is fully depressed.

Remove:

- the hose and install the protective cap
- the collecting bottle.

INSTALL THE BRAKE CALIPER

See **INSTALL THE LOCATING PINS IN THE BRAKE CALIPER** .

Finishing work

See **FINISHING WORK**.

REPLACING THE BRAKE FLUID (USING A BLEEDING UNIT)

GUIDELINES FOR BRAKE FLUID REPLACEMENT

Fig. 18: Brake Fluid And Reservoir
Courtesy of VOLVO CARS CORPORATION

It is recommended that the brake fluid is replaced every 45, 000 km (30, 000 miles), or every other year. The fluid must be replaced annually on cars driven in conditions requiring hard and frequent braking, such as driving in mountains or tropical climates with high humidity.

Background

The oil must be replaced because it is hygroscopic (the fluid absorbs water molecules from the air). This absorption of water occurs through the brake hoses and brake fluid reservoir. These components are rubber and plastic respectively and are not completely sealed against water molecules. An increased water content in the brake fluid dramatically reduces its boiling point and causes corrosion in the brake system components. This results in damage to the brake system. Braking performance deteriorates markedly.

NOTE: **Use only Volvo Genuine Parts brake fluid (Volvo DOT 4+). Never reuse brake fluid. Always keep brake fluid well sealed in its original packaging.**

PREPARATIONS FOR CHANGING, FRONT

Fig. 19: Collecting Bottle, Hose And G-Clamp

Switch off the ignition.

Clean around the brake fluid reservoir filler cap.

Connect the bleeding unit

See **CONNECT THE BLEEDING UNIT** .

Take out:

- a collecting bottle and hose to collect brake fluid in.
- a G-clamp.

Remove the protective cap from the bleed nipple on the brake calipers.

Connect the collecting bottle hose.

CHANGING THE BRAKE FLUID, FRONT

Fig. 20: Changing The Brake Fluid, Front
Courtesy of VOLVO CARS CORPORATION

Open the nipple, approximately one turn.

Push the brake caliper piston to bottom of the caliper using a G clamp. Leave the G-clamp in pushed in position.

Pressurize the braking system with the bleeding unit.

Leave the bleed nipple open until the new brake fluid enters.

Close the nipple. Remove the hose.

Install the protective cap.

Remove the G-clamp from the brake caliper.

REMOVE THE BLEEDING UNIT

Fig. 21: Bleeding Unit Connected to Brake Fluid Reservoir
Courtesy of VOLVO CARS CORPORATION

Shut off the bleeding unit.

Depressurize the brake system by opening and closing a bleed nipple.

Remove the collecting bottle.

Remove the bleed unit connector from the brake fluid reservoir.

FINISHING WORK

Fig. 22: Bleeding Brake System
Courtesy of VOLVO CARS CORPORATION

NOTE: Depress the brake pedal repeatedly until the brake pistons are in the normal position.

Check the brake fluid level. Install the cover.

Wash off any spilled brake fluid. Use warm water and car shampoo.

Install the wheel

See **INSTALLING WHEELS** .

PREPARATIONS FOR REPLACEMENT, REAR

Take out:

- a collecting bottle and hose to collect brake fluid in
- a large pipe wrench
- a jimmy
- the bleeding unit.

CONNECT THE BLEEDING UNIT

See **CONNECT THE BLEEDING UNIT** .

Raise the car

REMOVE THE REAR BRAKE CALIPER

See **REMOVE THE RETAINING SPRINGS AND LOCATING PINS FOR THE BRAKE PADS.** .

NOTE: **Do not remove the outer brake pad from the brake caliper. It is bonded to the caliper.**

PRESS THE PISTON INTO THE BRAKE CALIPER

Fig. 23: Identifying Piston Pressed Into Caliper Using Pipe Wrench
Courtesy of VOLVO CARS CORPORATION

Remove the brake pad from the piston.

Press the piston into the caliper using the pipe wrench.

Reinstall the brake pad on the piston.

Remove the protective cap from the bleed nipple. Connect the collecting bottle hose.

REPLACING BRAKE FLUID, REAR

Fig. 24: Identifying Jimmy Inserted Between Brake Pads

Insert the jimmy between the brake pads (as a counterhold) to keep the piston in.

Open the bleed nipple, approximately one turn.

Pressurize the braking system using the bleeding unit

Leave the bleed nipple open until the new brake fluid enters.

Close the nipple. Remove the hose.

Reinstall the protective cap on the bleed nipple.

Remove the jimmy between the brake pads.

Install the brake caliper

See **INSTALL THE LOCATING PINS IN THE BRAKE CALIPER** .

Remove the bleeding unit

See **REMOVE THE BLEEDING UNIT**.

Finishing work

See **FINISHING WORK**.

BLEEDING THE REAR BRAKE SYSTEM (WITH BLEEDING UNIT)

NOTE: Bleeding an ABS brake system takes longer than bleeding a normal brake system.

GUIDELINES FOR BLEEDING

Fig. 25: Brake Fluid And Reservoir
Courtesy of VOLVO CARS CORPORATION

When reconditioning or replacing brake calipers, it is generally sufficient to bleed the relevant brake line as follows.

The brake pedal must be depressed throughout the operation. This is so that the brake system is not drained of brake fluid.

If the braking system has been completely or partly drained, bleed the whole system. A bleeding unit must be used that can pressurize the brake system to 0.2-0.3 MPa (29.0 - 43.5 psi).

NOTE: Use only Volvo Genuine Parts brake fluid specification DOT 4+.Never reuse brake fluid. Always keep brake fluid well sealed in its original packaging.

PREPARATIONS

Fig. 26: Brake Fluid Reservoir And Brake Fluid Collection Bottle
Courtesy of VOLVO CARS CORPORATION

Switch off the ignition.

Clean around the brake fluid reservoir filler cap.

Take out the special brake fluid collection bottle.

CONNECT THE BLEEDING UNIT

Fig. 27: Bleeding Unit Connected to Brake Fluid Reservoir
Courtesy of VOLVO CARS CORPORATION

Connect the bleeding unit to the brake fluid reservoir. Follow the manufacturer's instructions for connecting and using bleeding unit.

Pressurize the brake system. Check the connection to the brake fluid reservoir.

Depressurize the system after the check.

Raise the car and remove the wheels

BLEEDING THE LEFT FRONT WHEEL (RIGHT WHEEL ON RIGHT-HAND DRIVE CARS)

Fig. 28: Collection Bottle Hose Connected to Bleed Nipple
Courtesy of VOLVO CARS CORPORATION

Remove the protective cap from the bleed nipple. Connect the hose from the collection bottle.

Open the bleed nipple. Close it when there are no more air bubbles in the fluid coming out.

Tighten the bleed nipple.

Remove the hose from the bleed nipple. Reinstall the protective cap.

Bleeding the other wheels

Continue bleeding according to above in the following order:

- right front wheel

- left rear wheel

- right rear wheel.

Check for any leakage from the bleed nipples.

DEPRESSURIZE THE BRAKE SYSTEM

Fig. 29: Bleeding Unit Connected to Brake Fluid Reservoir

BRAKE CALIPERS REAR, REPLACING

NOTE: **As the illustrations in this service information are used for different model years and / or models, some variation may occur. However, the essential information in the illustrations is always correct.**

PREPARATION

Fig. 30: Bleeding Brakes
Courtesy of VOLVO CARS CORPORATION

Remove the wheel.

Secure the pedal in the depressed position. Use a pedal jack.

Clean the brake caliper thoroughly.

Remove the protective cap from the bleed nipple.

Install a plastic hose on the nipple.

Open the bleed nipple. Collect the brake fluid in a container (bottle). Shut the bleed nipple.

Slacken the off brake hose approximately half a turn.

REMOVING THE BRAKE CALIPER

Fig. 31: Identifying Brake Caliper And Brake Pads
Courtesy of VOLVO CARS CORPORATION

Remove the brake caliper and brake pads. See: **BRAKE PADS REAR, REPLACING**.

Unscrew the brake caliper from the brake hose.

Drain the remaining brake fluid.

INSTALLING THE BRAKE CALIPER

NOTE: For tightening torques, see: TIGHTENING TORQUE .

Fig. 32: Installing Brake Hose To Brake Caliper
Courtesy of VOLVO CARS CORPORATION

Insert the brake caliper on the hose and hand tighten.

Clean and install the brake pads and brake calipers. See **BRAKE PADS REAR, REPLACING**.

Tighten the brake hose. Tighten. See: **TIGHTENING TORQUE** .

NOTE: The brake hose must not be twisted. If necessary alter the hose at the other end (brake pipe end).

BLEEDING BRAKE SYSTEMS

Fill and bleed the brake system.

NOTE: Use only Volvo Genuine parts brake fluid (Volvo DOT 4+).

To bleed the brake system, see **BRAKE SYSTEM, BLEEDING (USING BLEEDING UNIT)** .

FINISHING

Check:

- the function of the brakes after bleeding. Check that there is no leakage
- brake fluid level.

Depress the brake pedal a few times. Check the level of the brake fluid reservoir. Top up if necessary.

Install the wheel. See: **INSTALLING WHEELS** .

BRAKE DISC REAR, REPLACING

NOTE: The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.

PREPARATORY WORK

Fig. 33: Identifying Manual Adjustment For Parking Brake
Courtesy of VOLVO CARS CORPORATION

If the car has manual adjustment for the parking brake, see the illustration and (1). Reset the parking brake. See **PARKING BRAKE, ADJUSTING** .

If the car has a self-adjusting parking brake.

Reassemble and lock the self-adjuster unit for the parking brake. See: **PARKING BRAKE SELF-ADJUSTMENT, RESETTING** .

REMOVAL

Fig. 34: Brake Caliper, Mounting Screws, Holder And Brake Disc
Courtesy of VOLVO CARS CORPORATION

Remove:

- the wheel
- the 2 mounting screws for the brake caliper holder. Hang the brake caliper from the spring using a wire
- the locating pin and the brake disc.

CLEANING AND CHECKING

Fig. 35: Brake Pads
Courtesy of VOLVO CARS CORPORATION

NOTE: Cleaning is important to prevent lateral run out at the brake disc. Clean the hub flange before installing the new brake disc.

Check the hub. If it is damaged, measure the lateral run out. See: **REAR WHEEL HUB, MEASURING LATERAL RUNOUT** .

Check the brake pads. See: **BRAKE PADS REAR, REPLACING**.

INSTALLATION

NOTE: For tightening torques, see: TIGHTENING TORQUE .

INSTALLING THE BRAKE DISC AND CALIPER HOLDER

Fig. 36: Brake Disc And Caliper Holder
Courtesy of VOLVO CARS CORPORATION

Install the brake disc.

NOTE: **Be careful when handling the new brake disc. Careless handling can cause damage to the brake disc (out-of-true).**

Install:

- the new brake disc. Tighten the locating pin. Tighten. See: **TIGHTENING TORQUE**
- the brake caliper and the caliper holder. Use 2 **new** mounting screws. Tighten. See: **TIGHTENING TORQUE** .

FINISHING

Depress the brake pedal a few times.

Check the fluid level in the brake fluid reservoir.

Top up if necessary.

ADJUSTING THE PARKING BRAKE

Fig. 37: Identifying Manual Adjustment For Parking Brake
Courtesy of VOLVO CARS CORPORATION

If the car has manual adjustment for the parking brake, see the illustration and (1). Adjust the parking brake. See: **PARKING BRAKE, ADJUSTING** .

If the car has a self-adjusting parking brake.

Activate the self-adjustment for the parking brake. See: **PARKING BRAKE SELF-ADJUSTMENT, RESETTING** .

Install the wheel. See: **INSTALLING WHEELS** .

BRAKE PADS REAR, REPLACING

NOTE: The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.

PREPARATIONS

Remove the wheels on both sides.

REMOVING BRAKE PADS

Fig. 38: Identifying Retaining Springs And Brake Pad Pins
Courtesy of VOLVO CARS CORPORATION

NOTE: **Minimum recommended pad thickness/replacement limit when installing new brake pads = 2 mm.**

Remove the retaining spring and locating pins for the brake calipers.

Remove:

- the securing spring (3) carefully so that it does not deform
- the protective caps (1) from the two locating pins (2)
- the locating pins, use hex socket 7 mm.

Fig. 39: Brake Caliper And Brake Pads
Courtesy of VOLVO CARS CORPORATION

Remove:

- the brake caliper from the holder
- the brake pads.

Hang the brake caliper in a steel wire from the rear spring so as not to damage the brake hose.

NOTE: Do not depress the brake pedal while the brake pads are removed.

CLEANING THE BRAKE CALIPER

Fig. 40: Brake Caliper And Dust Cover
Courtesy of VOLVO CARS CORPORATION

Clean and check the brake caliper and dust cover.

Clean and check the brake pad mating surfaces in the brake caliper and caliper holder.

Clean the sliding pins using a steel brush.

Check piston dust boot.

NOTE: **If the dust boot is damaged dirt may have penetrated the cylinder. If this is the case the caliper must be replaced.**

CHECKING THE BRAKE DISC

Check brake disc friction surfaces.

If the brake disc displays signs of out-of-true, check its lateral run out. See **BRAKE DISC REAR, CALIBRATING** .

Replace the brake disc if it displays signs of heavy wear, variable thickness or similar. To replace, see **BRAKE DISC REAR, REPLACING**.

NOTE: **Minimum disc thickness/replacement limit = 18.0mm. Minimum recommended disc thickness when installing new brake pads = 18.7mm.**

INSTALLATION

NOTE: **For tightening torques, see: TIGHTENING TORQUE .**

LUBRICATING THE SLIDING SURFACES

Fig. 41: Identifying Sliding Surfaces
Courtesy of VOLVO CARS CORPORATION

Lubricate the contact surfaces of the brake pads using silicone grease, part no. 1161687 (12 ml) or part no. 1161688 (50 ml).

(Do not lubricate the sliding pins)

INSTALLING THE BRAKE PADS

Press piston back into cylinder on brake caliper.

Check that the dust cover is correctly positioned.

Install:

- new brake pads
- the brake caliper.

Fig. 44: Identifying Retaining Springs And Brake Pad Pins
Courtesy of VOLVO CARS CORPORATION

NOTE: Check the rubber sleeves of the locating pins. Replace if necessary.

Insert the locating pins in the rubber sleeves.

Tighten the locating pins. Tighten. See: **TIGHTENING TORQUE** .

Install protective caps (1).

Install the retaining spring (3).

FINISHING

Fig. 45: Bleeding Brake System
Courtesy of VOLVO CARS CORPORATION

Check the brake fluid level in the reservoir.

Depress the brake pedal a few times. Check the level of the brake fluid reservoir.

Top up if necessary.

Install the wheels. See **INSTALLING WHEELS** .

PROPELLER SHAFT, SPECIAL INFORMATION

Operation Number(s):

NOTE: Removal steps in this procedure may contain installation details.

When disconnecting the propeller shaft from the bevel gear, final drive, or when changing propeller shaft, it is important to follow the method steps to avoid damage on the rubber gaiter on the middle universal joint.

Fig. 1: Identifying Universal Joint Rubber Gaiter
Courtesy of VOLVO CARS CORPORATION

There is a raised part inside the universal joint that may damage the rubber gaiter if the propeller shaft is moved aside to max. when disconnecting at either end or removing the propeller shaft.

Fig. 2: Identifying Protected Rubber Gaiter
Courtesy of VOLVO CARS CORPORATION

If the whole propeller shaft is to be removed, the rubber gaiter must be protected.

Cut a 35 mm long piece of, e. g., radiator hose or similar that has been discarded.

Cut up the hose along its length.

Press in the hose into the universal joint and secure it with a cable tie.

Fig. 3: Identifying Protection Of Propeller Shaft & Rubber Gaiter
Courtesy of VOLVO CARS CORPORATION

CAUTION: The propeller shaft may not be lifted without first protecting the rubber gaiter.

Fig. 4: Identifying Propeller Shaft & Jack

If any part of the propeller shaft is to be disconnected, use a jack to support that part of the propeller shaft until it is suspended.

If the whole propeller shaft is to be removed, both parts must be supported.

REMOVAL

PREPARATORY WORK

Ignition off.

Wait 3-4 minutes after the ignition has been switched off to reduce oil leaks on removal.

REMOVING THE CONTROL MODULE

Fig. 1: Active On Demand Coupling Control Module Screws
Courtesy of VOLVO CARS CORPORATION

NOTE: Clean the area around the control module thoroughly before beginning removal.

Position a container underneath the Active on Demand Coupling. Disconnect the connectors for the control module and the oil pump.

Remove:

- the 2 screws for the control module

- the control module with the sealing plate and the cupped washer.

REMOVING COMPONENTS FROM THE ACTIVE ON DEMAND COUPLING

Fig. 2: Choke Valve And Temperature/Pressure Sensor
Courtesy of VOLVO CARS CORPORATION

Remove the throttle valve and the temperature/pressure sensor from the coupling.

A = Throttle valve.

B = Temperature/pressure sensor.

Use a large pair of pliers for removal. Grip the end of the throttle valve. Hold the pliers stable and pull the valve straight out.

NOTE: **Make sure that no damage is caused when removing the throttle valve. The valve cannot be replaced separately. The throttle valve is removed in order to be installed in the control module. This is done to minimize the risk of damage occurring to the contacts when installing.**

Remove:

- the temperature/pressure sensor as above
- the O-ring from the throttle valve seat in the coupling housing.

INSTALLATION

INSTALLING COMPONENTS

Fig. 3: Active On Demand Coupling Components

Install:

- control module
- the sealing plate
- washer
- the throttle valve with O-rings
- the temperature/pressure sensor with O-ring
- the O-ring for the throttle valve seat
- the screws.

COMPONENTS THAT ARE INCLUDED IN THE KIT AND MUST BE REPLACED

Fig. 4: Active On Demand Coupling Control Module Kit
Courtesy of VOLVO CARS CORPORATION

- the temperature/pressure sensor with O-ring

- washer
- the O-ring for the throttle valve seat.

Position the sealing plate in the control module

Press the throttle valve and temperature/pressure sensor into place on the control module contacts. Place the cupped washer with the convex side against the temperature/pressure sensor.

Lubricate the sealing rings on the valves with oil, P/N 116 1641-4 (0.3 liters).

INSTALLING THE O-RING

Fig. 5: Active On Demand Coupling Control Module O-Ring
Courtesy of VOLVO CARS CORPORATION

Carefully check that the sealing surface on the control module and valve seats in the Active on Demand Coupling is clean. Ensure that there is no trace of cloth or paper.

Lubricate the new O-ring with oil, P/N 116 1641-4 (0.3 liters). Press the O-ring into place in its seat.

INSTALLING THE CONTROL MODULE FOR THE ACTIVE ON DEMAND COUPLING

Fig. 6: Installing Control Module For Active On Demand Coupling
Courtesy of VOLVO CARS CORPORATION

Install the control module and the valves for the coupling. Press the control module against the coupling housing while loosely installing the screws alternately. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS** .

Connect the connectors to the control module and the oil pump.

Fill the Active on Demand Coupling with oil. Check the oil level. See **REAR AXLE, DRIVE SHAFTS - REMOVAL, REPLACEMENT AND INSTALLATION** .

Erase any diagnostic trouble codes (DTCs).

Pay attention to the following when removing propeller shaft

Follow instructions. See **PROPELLER SHAFT, SPECIAL INFORMATION**

Remove the screws from the propeller shaft.

Use counterhold see **9512940** and socket see **9512928** .

Leave one screw in place by a few threads for safety.

NOTE: Certain vehicles with 6 cylinder engines have a rear CV joint with 6 screws, in such cases use see 9997057 . See below for replacement parts.

Fig. 24: Active On Demand Coupling
Courtesy of VOLVO CARS CORPORATION

Replacement part propeller shafts only have 4 screw holes on the rear CV joint. The flange on the Active on Demand Coupling has 8 threaded holes to fit propeller shafts with both 4 and 6 screws.

Fig. 25: Flange With Hole Pattern For Both 4 And 6 Bolts

Remove:

- the screws for the bearing for the propeller shaft in the center bearing member
- the screws for the center bearing member. Let the member rest on the exhaust system.

REMOVING THE PROPELLER SHAFT

Press the propeller shaft joints together. Detach the front joint from the flange for the bevel gear and move it to the side.

Remove:

- the screw from the rear joint and detach it from the flange
- the propeller shaft.

NOTE: Only applies to vehicles with 6-cylinder engines and CV joint with 4 bolts.

Clean the joint using isopropanol P/N 1161 721 or similar.

Use 4 new screws.

Lubricate the threads and underneath the screw heads. Use normal lubricating oil. Wipe off any excess

lubricating oil to prevent it getting between the flange surfaces.

NOTE: When it is difficult to use a protractor to take the measurement, see SCREWED JOINT, TORQUE/ANGLE TIGHTENING .

Tighten according to **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**

NOTE: There are cast markings on the propeller shaft CV joint's flange and on the flange just beside the bolt holes. The markings should be opposite each other.

Use counterhold see **9512940** and socket see **9512928** .

HINT: To angle tighten, mark the material and then the screw 120° in front of the marking. Then tighten so that the markings are opposite each other.

TEST DRIVING

WARNING: Ensure that the car is safely raised. Check that no objects are caught in the tire treads.

CAUTION: Carry out the test with the car raised so that all four wheels can rotate freely with the mounting at the ends of the control arms to prevent damage to the drive shafts.

NOTE: If the car has STC or DSTC, these functions must be disengaged. Press in the STC/DSTC button on the center console. Hold the button in for at least 2 seconds. The LED on the button must go out.

If the car is equipped with TRACS (traction control system) the function must be deactivated. This is carried out by removing the fuse for the ABS modulator in the engine compartment fusebox. Note that diagnostic trouble codes (DTCs) will be stored in the brake control module (BCM). These must be erased before returning the car to the customer. For further information about the integrated relay/fusebox, see the appropriate Wiring Diagram.

- Ignition off
- Raise the car so that all the wheels are clear of the ground
- Depress the brake pedal
- Move the gear selector to position P
- Start the engine and release the parking brake
- Move the gear selector to position D
- Release the brake pedal when the car is idling. At least one wheel on each axle must rotate
- Depress the accelerator pedal (AP) and maintain a speed of approximately 60-80 km/h. All wheels rotate at the same speed
- Release the accelerator pedal (AP)
- Select N immediately after releasing the accelerator pedal (AP)
- Apply the parking brake when the wheels are still rotating at 60-80 km/h. Check that the rear wheels stop abruptly and that the front wheels continue to rotate
- Release the parking brake and depress the brake pedal. All wheels must stop

- Move the gear selector to position D
- Release the brake pedal. Check that at least one wheel on each axle rotates
- Depress the brake pedal
- Move the gear selector to position P
- Start the engine with the parking brake applied. The indicator lamp in the driver information module (DIM) must light - signal to the differential electronic module (DEM)
- Move the gear selector to position D
- Release the brake pedal when the car is idling. Check that the front wheels rotate slowly and the rear wheels do not rotate.

WARNING: Ensure that the vehicle is safely raised. Check that no objects are caught in the tire treads.

CAUTION: The test must be carried out on a raised vehicle so that all four wheels are free to turn, with attachment a long way out on the link arms, so as not to damage the drive shafts.

NOTE: If the vehicle has STC or DSTC, the function must be deactivated.

HINT: Read the oil pressure sensor signal using parameter readout, graphical display.

- Ignition off.

- Raise the vehicle so that all the wheels hang free.
- Depress the brake pedal.
- Move the gear selector lever to the P position.
- Start the engine.
- Move the gear selector lever to the D position.
- Release the brake pedal so that the vehicle idles. At least one wheel on each axle should rotate.

Read the oil pressure sensor signal to check functionality. Oil pressure must be between 0.5 and 1.0 MPa.

- Switch off the engine.
- Move the gear selector lever to the P position.
- Engage the parking brake.
- Start the engine.
- Move the gear selector lever to the D position.
- Release the brake pedal slowly when the car is idling ("simulating starting in reverse").
- The front wheels should now rotate slower than normal and the rear wheels should be stationary.

Read the oil pressure sensor signal to check functionality. Oil pressure should be between 1.0 and 1.5 MPa.

DRIVELINE/AXLES

Rear Axle, Drive Shafts - Diagnostic Trouble Codes And Associated Procedures

DEM-0006: FEED PUMP. FAULTY SIGNAL (4T65 AWD; AW50/51 AWD; 2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-0006

Condition

Fig. 1: Identifying Differential Electronic Module
Courtesy of VOLVO CARS CORPORATION

The differential electronic module (DEM) checks if the signal from the feed pump is within the permitted limits by comparing the signal with a calculated value.

Diagnostic trouble code (DTC) ECM-0006 is stored if the control module receives a signal from the feed pump corresponding to a current higher than 8191 mA. The control module interprets this as a fault.

Diagnostic trouble code (DTC) DEM 0006 can be diagnosed with the engine running and the engine speed (RPM) >500 rpm.

Substitute Value

- Four wheel drive is blocked.

Possible Source

- Defective feed pump.

Fault symptom[s]

- Four wheel drive is not functioning.

- Ignition on
- Disconnect the 2-pin connector for the feed pump.

  Disconnect the connector from the differential electronic module (DEM) to the feed pump. Take a reading using a voltmeter between terminals #1 and #2 on the connector for the pump motor. The voltmeter should read battery voltage.

  If the voltage was OK, check the connector. Check for bent or damaged pins.

  Remedy as necessary.

DEM-0006: FEED PUMP. FAULTY SIGNAL (4T65 AWD; 2005-2006)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-0006

Condition

Fig. 13: Active On Demand Coupling Control Module
Courtesy of VOLVO CARS CORPORATION

The differential electronic module (DEM) checks if the signal from the feed pump is within the permitted range by comparing the signal with predefined parameters.

The diagnostic trouble code (DTC) is stored if the control module registers a incorrect signal, i. e. a current value outside the predefined parameters.

The diagnostic trouble code (DTC) can be diagnosed with the engine running and the engine speed (RPM) greater than 500 rpm.

Substitute Value

- Four wheel drive is disengaged.

Possible Source

- Damaged feed pump

  Signal too high

- Short-circuit to ground.
- Damaged cable harness to the feed pump

Signal too high

- Short-circuit to ground.

Fault symptom[s]

DEM-000B: OIL PRESSURE. INCORRECT VALUE (4T65 AWD; 2006)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-000B

Condition

Fig. 22: Active On Demand Coupling Control Module
Courtesy of VOLVO CARS CORPORATION

Differential Electronic Module (DEM) calculates an expected oil pressure increase in the AOC-unit (the mechanical clutch) during driving. The control module checks how reasonable the oil pressure change is by comparing the calculated value with the signal from the oil pressure sensor.

If the signal deviates too much from the expected value the control module interprets this as a malfunction, and the diagnostic trouble code is generated.

The diagnostic trouble code (DTC) can be diagnosed when driving.

Substitute Value

- Four wheel drive is disengaged.

Possible Source

- Damaged temperature sensor.
- Damaged AOC unit (mechanic clutch).
- Oil leakage.
- Damaged Differential Electronic Module (DEM).

Fault symptom[s]

- Four wheel drive is not functioning.

   - Use VCT2000 (or appropriate scan tool).

     HINT: Correct pressure should be 0.00 +/- 0.08 MPa.

   - Engine idling
   - Use VCT2000 (or appropriate scan tool).

     HINT: Correct pressure should be 0.38 +/- 0.08 MPa.

2. Test of temperature sensor.
   - Ignition on.
   - Use VCT2000 (or appropriate scan tool).

     HINT: Normal value for ambient temperature when the vehicle is cold and (+20 to +50 °C) when the vehicle is driven.

If wrong value is read out, then diagnostic trouble code should be erased and the sensor changed. After changing sensor, repeat the test procedure again.

NOTE: **There are two types of sensors, an 80 bar and a 40 bar. Differential electronic module (DEM) has hardware number 30759701, 30785483, 30759682, 30783198, 30735844, or 30783018, an 80 bar pressure sensor should be installed. FAULTY VOLTAGE

CHECKING THE STATUS

Fig. 104: Identifying Ignition ON

- Ignition on.

  Read off the voltage for the differential electronic module (DEM) and the central electronic module (CEM).

  The voltage must be able to be compared with the power supply to the central electronic module (CEM) +/-2.5 V.

  HINT: Compare to the battery voltage.

  The fault is permanent if the power supply to the differential electronic module (DEM) deviates by more than 2.5 V from the central electronic module (CEM).

If the voltage is correct, this is an indication that the fault was present previously but is not active at the moment, i. e. an intermittent fault.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-0005

Condition

Fig. 127: Identifying Differential Electronic Module
Courtesy of VOLVO CARS CORPORATION

The differential electronic module (DEM) checks if the signal from the control valve is within the permitted limits by comparing the signal with a calculated value.

Diagnostic trouble code (DTC) ECM-0005 is stored if the control module receives a signal from the control valve corresponding to a current higher than 4095 mA. The control module interprets this as a fault.

Diagnostic trouble code (DTC) DEM 0005 can be diagnosed with the engine running and the engine speed (RPM) >500 rpm.

The differential electronic module (DEM) checks if the signal from the control valve is within the permitted range by comparing the signal with a predefined parameter.

The diagnostic trouble code (DTC) is stored if the control module registers a incorrect signal, i. e. a current value outside the predefined parameters.

The diagnostic trouble code (DTC) can be diagnosed with the engine running and the engine speed (RPM) greater than 500 rpm.

Substitute Value

- Four wheel drive is disengaged.

Possible Source

- Damaged control module.

Fault symptom[s]

DEM-0007: HYDRAULIC PRESSURE. INCORRECT VALUE (4T65 AWD; AW50/51 AWD; 2005)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-0007

Condition

Fig. 131: Active On Demand Coupling Control Module
Courtesy of VOLVO CARS CORPORATION

The Differential electronic module (DEM) checks the oil pressure in the Haldex clutch using an oil pressure sensor.

When the engine speed exceeds 500 rpm, an initial pressure builds up in the clutch via an electric feed pump.

The diagnostic trouble code (DTC) is stored if the control module detects that:

- Initial pressure not reached within 2-4 minutes.

The control module's test for the diagnostic trouble code (DTC) starts in the event of:

- Engine speed (RPM) higher than 500 rpm.

Substitute Value

- Four wheel drive is disengaged.

Possible Source

- Damaged pressure sensor.

- Damaged feed pump.
- Too low oil volume in clutch.
- Internal leak in the clutch.

Fault symptom[s]

- Four wheel drive is not functioning.

- Ignition on.

Read off the oil pressure in the Differential Electronic Module (DEM). The pressure must rise when the engine speed exceeds 500 rpm. Use **VIDA (Volvo scan tool)** .

First read off the oil pressure with the ignition on and then with the engine running. At read out, the oil pressure must rise when the engine rpm exceeds 500 rpm, the pressure must rise immediately after the engine's rpm increases.

If the pressure does not rise, this means that a fault has occurred.

DEM-0007: HYDRAULIC PRESSURE. INCORRECT VALUE (4T65 AWD; AW50/51 AWD; 2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-0007

Condition

Fig. 140: Identifying Differential Electronic Module
Courtesy of VOLVO CARS CORPORATION

The differential electronic module (DEM) checks the signal from the oil pressure sensor by comparing the signal with a calculated value.

When the engine speed (RPM) exceeds 500 rpm, the control module calculates the pressure theoretically. The calculated pressure is compared to the oil temperature sensor signal. Diagnostic trouble code (DTC) DEM-007 is stored if the calculated temperature deviates from the calculated value. The control module interprets this as a fault.

Diagnostic trouble code (DTC) DEM-0007 can be diagnosed with the engine running and the engine speed (RPM) >500 rpm.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION

Condition

Fig. 157: Identifying Differential Electronic Module
Courtesy of VOLVO CARS CORPORATION

The differential electronic module (DEM) checks the software calibration.

Diagnostic trouble code (DTC) DEM-0008 is stored if the control module registers a fault in the internal calibration software.

Diagnostic trouble code (DTC) DEM-0008 can be diagnosed with the engine running and the engine speed (RPM) >500 rpm.

Substitute Value

- Four wheel drive is blocked.

Possible Source

- Defective control module.

Fault symptom[s]

- Four wheel drive is not functioning.

INTERNAL FAULT

REPLACING THE CONTROL MODULE

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-0009

Condition

Fig. 159: Active On Demand Coupling Control Module
Courtesy of VOLVO CARS CORPORATION

The differential electronic module (DEM) checks the function at the Analog/Digital converter by comparing the analog power supply with the corresponding digital power supply (after Analog/Digital conversion).

The diagnostic trouble code (DTC) is stored if the signal from the Analog/Digital converter deviates from the power supply.

The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute Value

- Four wheel drive is disengaged.

Possible Source

- Internal fault (Analog/Digital converter not working).

Fault symptom[s]

- Four wheel drive is not functioning.

INTERNAL FAULT

INFORMATION

The differential electronic module (DEM) has registered an internal fault.

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the differential electronic module (DEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. Replace the differential electronic module (DEM) if the fault recurs.

Other information:

- For AW50AWD and 4T65AWD 2003-, see **DIFFERENTIAL ELECTRONIC MODULE (DEM), REPLACING**
- For TF-80SC 2005- see **DIFFERENTIAL ELECTRONIC MODULE (DEM), REPLACING (2005-2008)** .

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-000A

Condition

Fig. 163: Active On Demand Coupling Control Module
Courtesy of VOLVO CARS CORPORATION

The differential electronic module (DEM) continuously checks if the power supply to the control module is within its permitted range. The differential electronic module (DEM) compares the signal with the predefined parameter.

Diagnostic trouble code (DTC) DEM is stored if the control module registers a power supply lower than 8.5 V for 25 seconds or greater than 18.5 V for 3 seconds.

The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute Value

- Four wheel drive is disengaged.

Possible Source

Signal too high:

- Short-circuit to ground.

Signal too low:

- Open-circuit in the power supply.

Fault symptom[s]

- Four wheel drive is not functioning.

The differential electronic module (DEM) checks the configuration in the connector to the control module for the Active on Demand Coupling. This is to prevent a control module from another make of car being installed by accident.

NOTE: A control module from another make of car with the same four wheel drive system can be incorrectly installed in a Volvo.

The diagnostic trouble code (DTC) is stored if the control module does not recognize the configuration.

The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

The control modules transmit and receive information via a standardized serial communication method - CAN (Control Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference (CAN communication blocked).

NOTE: **In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the fault if it is intermittent.**

Substitute Value

- The control module shuts itself off ("bus-off")

  HINT: The control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

Possible Source

- Short-circuit between the control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Internal fault in the control module

- Internal fault in another control module in the same part of the control area network (CAN).

FAULT-TRACING

FAULT-TRACING INFORMATION

Use the following information and general checks during fault-tracing.

NOTE: Check that the fuses are intact. For locations, see the owner's manual, cover for fuse box, fuse ratings or similar.

1. Check, if possible, relevant functions in the vehicle using buttons/controls/test drives to determine the status of the fault.

   NOTE: If the vehicle does not show any of the given symptoms in the diagnostic trouble code information (DTC), this may mean that the fault is intermittent or that the control module is not detecting the fault at this moment.

2. Use the diagnostic trouble code's **frozen values** , **status identifiers** and **counter** to determine the operating conditions when the fault was detected, the fault's current status and any degree of intermittence

of the fault.

3. Check and fault-trace according to **the fault causes** that are specified in the **diagnostic trouble code (DTC) information** .
4. Use **VIDA (Volvo scan tool)** . Read off the parameters, activate components and functions, carry out quick tests and checking routines for the diagnostic trouble codes to identify the fault.
5. Check relevant components according to **Component specifications** .
6. Check relevant signals according to appropriate **signal specification** and **breakout box** service information.

Condition

Fig. 201: Active On Demand Coupling Control Module

The Differential Electronic Module (DEM) checks the function of the A/D converter by comparing the power supply with the predefined limits.

If the signal from the A/D converter is extreme and outside the limits, the control module interprets this as a fault and the trouble code is set.

The diagnostic trouble code can be diagnosed when the ignition is on.

Substitute Value

- Four wheel drive is disengaged.

Possible Source

- Damaged control module.

Fault symptom[s]

- Four wheel drive is not functioning.

FAULT TRACING DEM-P060749

INFORMATION

The Differential Electronic Module (DEM) has registered an internal fault.

If the fault is intermittent this means that it has been registered on an earlier occasion but that the fault is no longer present. Intermittent faults can depend upon disturbances during the start up of the Differential Electronic Module (DEM) or they can be other types of fault which can return on different occasions. An appraisal of the fault is made in each particular case. If the fault is persistent, replace the Differential Electronic Module (DEM).

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-P064F05

Condition

Information about the vehicle configuration is sent on the CAN network. Depending on the model and equipment, the vehicle can be configured in different ways. The central electronic module (CEM) sends the applicable signal ID for the vehicle. The differential electronic module (DEM) compares its configuration ID with the signal configuration transmitted on the network by the central electronic module (CEM).

The diagnostic trouble code (DTC) is stored if the control module detects that:

- These do not correspond, which means that the wrong software is programmed in Differential electronic module (DEM).

The control module's test for the diagnostic trouble code (DTC) starts in the event of:

- Ignition switch position II.

NOTE: **The control module can only detect the fault once the test has been started and the diagnostic trouble code (DTC) is stored when the conditions are met.**

FAULT-TRACING

GENERAL INFORMATION

The diagnostic trouble code (DTC) is stored when the communication between the central electronic module (CEM) and the relevant control module has been interrupted. There can be a number of causes for interruptions in the communication:

- Faulty signal configuration in the control module that stored the diagnostic trouble code (DTC). The fault can be due to a customer or workshop replacing a control module without downloading new software for the replacement
- Intermittent open-circuit in one or both CAN cables in part of the network
- Intermittent short-circuits between the CAN cables
- Intermittent short-circuits between one of the CAN cables and ground or supply voltage
- Internal fault in the control module that stored the diagnostic trouble code (DTC).

The fault can also be due to faulty software in a control module, a hardware problem in the CAN network (faulty cables) or a fault in a control module.

NOTE: **If there is a diagnostic trouble code (DTC) for a communication fault in a control module, check whether diagnostic trouble codes (DTCs) have been stored in the central electronic module (CEM). The central electronic module (CEM) monitors the voltage level in the CAN cables and is the only control module that can directly store a diagnostic trouble code (DTC) for a short-circuit in one of the cables for ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a CAN fault unless fault-tracing has indicated that the central electronic module (CEM) has an internal fault.**

Corrective actions

1. If this diagnostic trouble code (DTC) is the only communication diagnostic trouble code (DTC) stored in one of the control modules in the high speed network, try to remedy the fault by downloading new software for the control module that stored the diagnostic trouble code (DTC)
2. Check the cables in the CAN network according to the following fault-tracing
3. The control module should be replaced as a last resort.

Other information

- see **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK (2005-2012)**
- Go to the tab software and program the control module with the latest software.
- **Continue**

  Refer to **VERIFICATION**

VERIFICATION

Fig. 204: Identifying Ignition ON
Courtesy of VOLVO CARS CORPORATION

- Ignition on
- Wait for 20 seconds.

NOTE: **This first verification assumes that download of new software was required in the control module that generated the diagnostic trouble code. If download of new software was not required: read out diagnostic trouble codes and check if the code status is permanent or intermittent to learn how difficult it will be to find the fault.**

Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Check that the diagnostic trouble code (DTC) for faulty communication is not stored again.

Has the fault been remedied?

- **YES**

  OKAY: Troubleshooting has been completed.

- **NO**

  Refer to **TAKING READING ON CABLE IN THE CAN NETWORK (HS-CAN)**

TAKING READING ON CABLE IN THE CAN NETWORK (HS-CAN)

Fig. 205: Identifying Ignition OFF

- Ignition off

- Disconnect the battery negative lead.
- Remove the central electronic module (CEM)
- Connect the breakout box to the cable harness for the central electronic module (CEM). Do not connect the central electronic module (CEM).

HINT: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

Disconnect the CAN network to make it easier to locate a fault. A suitable point to disconnect the network is at the central electronic module (CEM). Fault-tracing therefore starts from the central electronic module (CEM).

Take resistance readings across the following terminals. Various readings will be obtained due to the structure of the network. Twist the cable harness and work the connectors at accessible points along the cable harness in order to check whether the resistance changes during each measurement. This method can be used to detect intermittent short-circuits or open-circuits.

NOTE: The following resistance readings only measure the main arteries in the high speed network, not the junctions that exist for some control modules. If an open-circuit is suspected in a cable, or a short-circuit is suspected in one of its junctions, the connector at the control module for this junction must be disconnected and the reading taken from there.

Take the following readings

- Resistance between C3:47 and C3:48. Resistance should be 120 ohms.

  NOTE: Measuring will only give value 120 ohms if the main circuit in the CAN-net is intact. If there is a short-circuit somewhere in the CAN-net (either main circuit or other branching) the resistance will be 0 ohms.

- The resistance between C3:48 and a connection to voltage as well as between C3:48 and a short-circuit to ground. The resistance should be very high (more than 1 Mohms).
- The resistance between C3:47 and a connection to voltage as well as between C3:47 and a short-circuit to ground. The resistance should be very high (more than 1 Mohms).

HINT: Any short-circuit detected on the CAN-net may be on the main circuit or on any branching running out to some control modules. If a fault is found, try to disconnect the junction with the fault at a point further forward. Try to locate the fault in this way.

Remedy as necessary.

Was a fault detected?

- **YES**

CHECKING THE TRAFFIC LOAD ON THE CAN CABLES

Fig. 206: Identifying Ignition ON

- Connect the central electronic module (CEM) to the breakout box
- Connect the battery.
- Ignition on

NOTE: **When the adapter cable harness and the central electronic module (CEM) have been connected, there is access to both sides of the CAN network (both LS-CAN and HS-CAN). There will also be traffic on both networks. Be careful to check the terminals between which the readings are to be taken so that the intended reading is not taken on the wrong network.**

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount

of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Check as follows:

- Measure the voltage between C3:48 and ground. The voltage should be approx. 2.3 V.
- Measure the voltage between C3:47 and ground. The voltage should be approx. 2.8 V.

Other information

- see **CONNECTING THE BREAKOUT BOX**
- see **BATTERY, DISCONNECTING**

Is the value OK?

- **YES**

  Refer to **INFORMATION**

- **NO**

  Refer to **IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK**

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Check communication/load on HS-CAN by measuring voltage between C3:48 and C3:47. The voltage's average value should be approx. 0.5 V (permitted is 0.4 to 0.6 V). In case of communication error, the voltage is approx. 0.7 V and higher.

In order to identify which control module is communicating incorrectly, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Continue until the voltage between the CAN cables drops to approximately 0.5 V.

HINT: When the suspected control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears. Ignition off between each check.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced.

NOTE: A faulty control module that disrupts communication can place other control modules in Limp-Home mode (i. e. they work but with limited functionality) even after switching the ignition off and on a number of times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

Remedy as necessary.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-P093215

Condition

Fig. 18: Control Module And Oil Temperature Sensor
Courtesy of VOLVO CARS CORPORATION

The Differential Electronic Module (DEM) checks that the signal from the oil pressure sensor is appropriate. If the signal from the oil pressure sensor is higher than the predefined upper limit, the control module interprets this as a fault and the trouble code is set.

The diagnostic trouble code can be diagnosed when the ignition is on.

Substitute Value

- Four wheel drive is disengaged.

Possible Source

- Connector resistance and oxidation in the connectors.
- Damaged oil pressure sensor.
- Damaged control module.

Fault symptom[s]

- Four wheel drive functions badly.

- Check the connector between the Differential Electronic Module (DEM) and the oil pressure sensor with respect to contact resistance and oxidation.
- Check connector A with respect to depressed or damaged pins, contact resistance and oxidation.
- Start the engine and read the value of the oil pressure sensor signal in order to check the function.

  HINT: The oil pressure should be 0.8 MPa when the engine is idling. The oil pressure sensor has a measurement range from 0 to 4 MPa.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-P096162

Condition

Differential Electronic Module (DEM) calculates an expected oil pressure increase in the AOC-unit (the mechanical clutch) during driving. The control module checks reasonableness of the oil pressure change.

The diagnostic trouble code (DTC) is stored if the control module detects that:

- The signal from the oil pressure sensor deviates too much from the predefined value.
- Incorrect value lasts longer than 5 minutes.

The control module's test for the diagnostic trouble code (DTC) starts when:

- The oil temperature is between -40 °C and 120 °C.
- 30 seconds since the test was run the last time.
- The torque transfer is below a certain level that can be calibrated.
- The lateral acceleration is below a certain level that can be calibrated.

- No ABS engagement.
- No antispin engagement.

NOTE: The control module can only detect the fault once the test has been started and the diagnostic trouble code (DTC) is stored when the conditions are met.

Substitute Value

- Four wheel drive is disengaged.

Possible Source

- Damaged control valve/axial solenoid.
- Damaged AOC unit (mechanic clutch).
- Oil leakage.
- Damaged Differential Electronic Module (DEM).

Condition

Fig. 85: Active On Demand Coupling Control Module

The Differential Electronic Module (DEM) calculates an expected oil pressure change in the AOC unit (mechanical clutch) during driving. The control module checks whether the oil pressure change is appropriate by comparing the calculated value with the signal from the oil pressure sensor.

If the signal has too great a divergence from the expected value, the control module interprets this as a fault and the trouble code is set.

The diagnostic trouble code (DTC) can be diagnosed when driving.

Substitute Value

- Four wheel drive is disengaged.

Possible Source

- Damaged Differential Electronic Module (DEM).
- Damaged AOC unit (mechanic clutch).
- Oil leak.

CHECKING THE FUNCTION

Fig. 86: Belt Routing / Engine Idling - Volvo
Courtesy of VOLVO CARS CORPORATION

CAUTION: Carry out the test with the vehicle raised so that all four wheels can rotate freely with the mounting at the ends of the control arms to prevent damage to the drive shafts.

WARNING: Ensure that the vehicle is safely raised. Check that no objects are caught in the tire treads.

NOTE: If the vehicle has TRACS or TC (STC, DSTC) this function must be deactivated. This is done by removing the fuse for the brake system pump motor from the engine compartment electrical center. Note that this will cause trouble codes to be set in the Brake Control Module (BCM). These codes must be erased before the vehicle is returned to the customer.

- Engine idling.
- Read off the oil pressure.

  Check that the function is OK by test running the vehicle on a lift (to increase the clutch oil pressure). Run the car in a low gear or in "Drive" with an automatic transmission. Apply the handbrake slightly and read the pressure value during the test. Check that the pressure is updated. Listen as well for abnormal noises from the clutch.

  HINT: The oil pressure sensor has a measurement range of 0 to 4 MPa.

  Also check the clutch for leakage.

  Remedy as necessary.

FAULT TRACING DEM-118854

INFORMATION

The Differential Electronic Module (DEM) has registered an internal fault.

If the fault is intermittent this means that it has been registered on an earlier occasion but that the fault is no longer present. Intermittent faults can depend upon disturbances during the start up of the Differential Electronic Module (DEM) or they can be other types of fault which can return on different occasions. An appraisal of the fault is made in each particular case. If the fault is persistent, replace the Differential Electronic Module (DEM).

NOTE: **This diagnostic trouble code (DTC) status is an event controlled diagnostic trouble code (DTC). An event controlled diagnostic trouble code (DTC) does not mean that there is a fault in the control module when it is active, but is designed as information.**

Differential electronic module (DEM) checks engagement and disengagement of four-wheel drive. The control module controls engagement and disengagement using a number of parameters, among others, by comparing speed of the wheels. If the vehicle's tires are worn unevenly (compared front and rear, or if a tire with incorrect dimension is installed (compared with the vehicle's other tires) on the vehicle's front or rear axle, this may result

in incorrect engagement of four-wheel drive.

The diagnostic trouble code (DTC) is stored if the control module detects that:

- Any of the wheels on the front or rear axle rotate faster than other wheels when driving on straight road with constant throttle application.

The control module's test for the diagnostic trouble code (DTC) starts in the event of:

- Constant vehicle speed (above 20 km/h).

The Differential Electronic Module (DEM) checks if the signal from the control valve is appropriate by comparing the signal with predefined limit values.

If the control unit registers a faulty signal, i. e. a current value (amperes) that is outside the predefined limits, the trouble code is set.

The diagnostic trouble code can be diagnosed when the engine is running.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-P16891D

Condition

The Differential electronic module (DEM) checks the performance of the control valve/the axial solenoid. The control module controls the solenoid by controlling the current via an internal control circuit. The control module checks the solenoid by comparing the current to the predefined parameters.

The diagnostic trouble code (DTC) is stored if the control module detects that:

- The amperage to the control valve/the axial solenoid deviates more than 0.2 A from the desired value.
- Incorrect value runs longer than 1 second.

The control module's test for the diagnostic trouble code (DTC) starts in the event of:

- Normal driving.

NOTE: The control module can only detect the fault once the test has been started and the diagnostic trouble code (DTC) is stored when the conditions are met.

TEST DRIVING

Fig. 165: Identifying Test Drive
Courtesy of VOLVO CARS CORPORATION

WARNING: **Observe all traffic regulations during the test drive.**

HINT: The test drive consists of two tests. The first test is at low engine speeds (RPM). The second is at higher engine speeds (RPM).

HINT: At low engine speeds (RPM), four wheel drive is normally disengaged. At high engine speeds, four wheel drive will be engaged. This will have a braking effect when the clutch is depressed and the accelerator pedal (AP) is released.

HINT: The stopping distance with four wheel drive engaged must be approximately half the distance of that when four wheel drive is disengaged.

The test drive

Drive the car in a circle at full lock (the smallest turning circle) at a speed of approximately 10 km/h. Press the clutch and release the accelerator pedal (AP). Let the car come to a standstill.

Note how long it took for the car to stop.

Repeat the test. Increase the engine speed to 3000-4000 RPM. Let the car come to a standstill.

The car will stop in half the distance it took to stop in the first test if the function is correct.

Drive the car while looking out for any faults in functions or noise from the rear suspension.

If there is a fault or noise, stop the test drive. Return to the workshops. Fault trace the symptoms.

- Ignition on.

Read off the oil pressure in the Differential Electronic Module (DEM). The pressure must rise when the engine speed exceeds 500 RPM. Use **VIDA Vehicle communication** .

First read off the oil pressure with the ignition on and then with the engine running. At read out, the oil pressure must rise when the engine RPM exceeds 500 RPM, the pressure must rise immediately after the engine's RPM increases.

If the pressure does not rise, this means that a fault has occurred.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-P18897A

Condition

The Differential electronic module (DEM) checks the performance of the oil pressure pump. The control module compares the current strength from the oil pressure pump to the predefined parameters.

The diagnostic trouble code (DTC) is stored if the control module detects that:

- The oil pressure pump runs for longer than 20 seconds.

The control module's test for the diagnostic trouble code (DTC) starts in the event of:

- Engine running.
- 1 second after the accumulator has been topped up. The test is performed during a four second period but is cancelled if the accumulator requires topping up.
- The oil temperature is between 0 - 80 °C.

NOTE: **The control module can only detect the fault once the test has been started and the diagnostic trouble code (DTC) is stored when the conditions are met.**

FAULT-TRACING

FAULT-TRACING INFORMATION

This malfunction is caused by a damaged non-return valve in the oil filter or by a clogged oil filter. Solved by changing oil filter as well as oil in AOC (active on demand coupling).

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-P188A68

Condition

NOTE: **This diagnostic trouble code (DTC) status is an event controlled diagnostic trouble code (DTC). An event controlled diagnostic trouble code (DTC) does not mean that there is a fault in the control module when it is active, but is designed as information.**

The Differential Electronic Module (DEM) has a temperature sensor fitted on the control module's circuit board. The sensor provides the Differential Electronic Module (DEM) with information about the temperature in the control module. If the temperature exceeds a preset value all wheel drive is disabled. This is to protect the components from a too high load, which can result in internal mechanical faults.

The diagnostic trouble code (DTC) is stored if the control module detects that:

- The temperature is higher than 110 °C.
- Incorrect value lasts longer than 3 seconds.

The control module's test for the diagnostic trouble code (DTC) starts in the event of:

- Ignition switch position II.

NOTE: **The control module can only detect the fault once the test has been started and the diagnostic trouble code (DTC) is stored when the conditions are met.**

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-U030000

Condition

The control modules communicate with each other for exchange of information in a network via a standardized serial communication procedure - CAN (Controller Area Network). The Central electronic module (CEM) regularly transmits messages on the CAN network. These messages contain information about which signal configuration ID applies to the vehicle. The control modules on the CAN network have the same signal configuration ID so that they can communicate with each other.

The control module compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM).

The diagnostic trouble code (DTC) is stored if the control module detects that:

- The control module's configuration ID differ from the ID that the Central electronic module (CEM)

transmits.

The control module's test for the diagnostic trouble code (DTC) starts in the event of:

- Starting the control module's CAN communication.

NOTE: The control module can only detect the fault once the test has been started and the diagnostic trouble code (DTC) is stored when the conditions are met.

Substitute Value

- Control module shuts itself off ("bus-off").

NOTE: When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic commands.

Possible Source

- Incorrect configuration ID (the control module is not intended for this vehicle, for example it is a used control module with different software/hardware).
- Open-circuit in the CAN cables between the control module and the Central Electronic Module (CEM).

Fault symptom[s]

- 4-wheel/all wheel drive/Does not work

FAULT-TRACING

GENERAL INFORMATION

The diagnostic trouble code (DTC) is stored when the communication between the central electronic module (CEM) and the relevant control module has been interrupted. There can be a number of causes for interruptions in the communication:

- Faulty signal configuration in the control module that stored the diagnostic trouble code (DTC). The fault can be due to a customer or workshop replacing a control module without downloading new software for the replacement
- Intermittent open-circuit in one or both CAN cables in part of the network
- Intermittent short-circuits between the CAN cables
- Intermittent short-circuits between one of the CAN cables and ground or supply voltage
- Internal fault in the control module that stored the diagnostic trouble code (DTC).

The fault can also be due to faulty software in a control module, a hardware problem in the CAN network (faulty cables) or a fault in a control module.

NOTE: **If there is a diagnostic trouble code (DTC) for a communication fault in a control module, check whether diagnostic trouble codes (DTCs) have been stored in the central electronic module (CEM). The central electronic module (CEM) monitors the voltage level in the CAN cables and is the only control module that can directly store a diagnostic trouble code (DTC) for a short-circuit in one of the cables for ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a CAN fault unless fault-tracing has indicated that the central electronic module (CEM) has an internal fault.**

Corrective actions

1. Check the cables in the CAN network according to the following fault-tracing
2. If this diagnostic trouble code (DTC) is the only communication diagnostic trouble code (DTC) stored in one of the control modules in the high speed network, try to remedy the fault by downloading new software for the control module that stored the diagnostic trouble code (DTC)
3. The control module should be replaced as a last resort.

Other information

- see **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK (2005-2012)**
- Go to the tab software and program the control module with the latest software.

- **Continue**

  Refer to **VERIFICATION**

VERIFICATION

Fig. 208: Identifying Ignition ON
Courtesy of VOLVO CARS CORPORATION

- Ignition on
- Wait for 20 seconds.

NOTE: **This first verification assumes that download of new software was required in the control module that generated the diagnostic trouble code. If download of new software was not required: read out diagnostic trouble codes and check if the code status is permanent or intermittent to learn how difficult it will be to find the fault.**

Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Check that the diagnostic trouble code (DTC) for faulty communication is not stored again.

Has the fault been remedied?

- **YES**

  OKAY: Troubleshooting has been completed.

- **NO**

  Refer to **TAKING READING ON CABLE IN THE CAN NETWORK (HS-CAN)**

TAKING READING ON CABLE IN THE CAN NETWORK (HS-CAN)

Fig. 209: Identifying Ignition OFF

- Ignition off

- Disconnect the battery negative lead.
- Remove the central electronic module (CEM)
- Connect the breakout box to the cable harness for the central electronic module (CEM). Do not connect the central electronic module (CEM).

HINT: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

Disconnect the CAN network to make it easier to locate a fault. A suitable point to disconnect the network is at the central electronic module (CEM). Fault-tracing therefore starts from the central electronic module (CEM).

Take resistance readings across the following terminals. Various readings will be obtained due to the structure of the network. Twist the cable harness and work the connectors at accessible points along the cable harness in order to check whether the resistance changes during each measurement. This method can be used to detect intermittent short-circuits or open-circuits.

NOTE: The following resistance readings only measure the main arteries in the high speed network, not the junctions that exist for some control modules. See the appropriate service information for the relevant car model. If an open-circuit is suspected in a cable, or a short-circuit is suspected in one of its junctions, the connector at the control module for this junction must be disconnected and the reading taken from there.

Take the following readings

- Resistance between C3:47 and C3:48. Resistance should be 120 ohms.

  NOTE: Measuring will only give value 120 ohms if the main circuit in the CAN-net is intact. If there is a short-circuit somewhere in the CAN-net (either main circuit or other branching) the resistance will be 0 ohms.

- The resistance between C3:48 and a connection to voltage as well as between C3:48 and a short-circuit to ground. The resistance shall be very high (more than 1 Mohms).
- The resistance between C3:47 and a connection to voltage as well as between C3:47 and a short-circuit to ground. The resistance shall be very high (more than 1 Mohms).

HINT: Any short-circuit detected on the CAN-net may be on the main circuit or on any branching running out to some control modules. If a fault is found, try to disconnect the junction with the fault at a point further forward. Try to locate the fault in this way.

Remedy as necessary.

Other information

- see **CHECKING WIRING AND TERMINALS**

Was a fault detected?

- **YES**

  Refer to **VERIFICATION**

- **NO**

  Refer to **CHECKING THE TRAFFIC LOAD ON THE CAN CABLES**

CHECKING THE TRAFFIC LOAD ON THE CAN CABLES

- Connect the central electronic module (CEM) to the breakout box
- Connect the battery.
- Ignition on

NOTE: **When the adapter cable harness and the central electronic module (CEM) have been connected, there is access to both sides of the CAN network (both LS-CAN and HS-CAN). There will also be traffic on both networks. Be careful to check the terminals between which the readings are to be taken so that the intended reading is not taken on the wrong network.**

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount

of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Check as follows:

- Measure the voltage between C3:48 and ground. The voltage shall be approx. 2.3 V.
- Measure the voltage between C3:47 and ground. The voltage shall be approx. 2.8 V.

Other information

- see **CONNECTING THE BREAKOUT BOX**
- see **BATTERY, DISCONNECTING**

Is the value OK?

- **YES**

  Refer to **INFORMATION**

- **NO**

  Refer to **IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK**

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Check communication/load on HS-CAN by measuring voltage between C3:48 and C3:47. The voltage's average value shall be approx. 0.5 V (permitted is 0.4 to 0.6 V). In case of communication error, the voltage is approx. 0.7 V and higher.

In order to identify which control module is communicating incorrectly, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Continue until the voltage between the CAN cables drops to approximately 0.5 V.

HINT: When the suspected control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears. Ignition off between each check.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced.

NOTE: A faulty control module that disrupts communication can place other control modules in Limp-Home mode (i. e. they work but with limited functionality) even after switching the ignition off and on a number of times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

Remedy as necessary.

- **Continue**

  Refer to **VERIFICATION**

HINT: Once a fault has been repaired, conduct a verification to check that the fault has been remedied.

The Control module compares its configuration ID with the signal configuration which the Central Electronic Module (CEM) transmits on the Control Area Network (CAN). If the two configurations do not agree the trouble code is set. The trouble code is also set if communication between the control module and the Central Electronic Module (CEM) is interrupted.

NOTE: **If communication is interrupted in both CAN leads it is not possible to communicate with the control module. Therefore it will only be possible to read the trouble code if the fault is intermittent. When the trouble code is set the control module will respond to a diagnostic command even though the normal CAN communication is not functioning (Expulsion mode).**

FAULT-TRACING

GENERAL INFORMATION

The diagnostic trouble code (DTC) is stored when the communication between the central electronic module (CEM) and the relevant control module has been interrupted. There can be a number of causes for interruptions in the communication:

- Faulty signal configuration in the control module that stored the diagnostic trouble code (DTC). The fault can be due to a customer or workshop replacing a control module without downloading new software for the replacement
- Intermittent open-circuit in one or both CAN cables in part of the network
- Intermittent short-circuits between the CAN cables
- Intermittent short-circuits between one of the CAN cables and ground or supply voltage
- Internal fault in the control module that stored the diagnostic trouble code (DTC).

The fault can also be due to faulty software in a control module, a hardware problem in the CAN network (faulty cables) or a fault in a control module.

NOTE: **If there is a diagnostic trouble code (DTC) for a communication fault in a control module, check whether diagnostic trouble codes (DTCs) have been stored in the central electronic module (CEM). The central electronic module (CEM) monitors the voltage level in the CAN cables and is the only control module that can directly store a diagnostic trouble code (DTC) for a short-circuit in one of the cables for ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a CAN fault unless fault-tracing has indicated that the central electronic module (CEM) has an internal fault.**

Corrective actions

1. Check the cables in the CAN network according to the following fault-tracing
2. If this diagnostic trouble code (DTC) is the only communication diagnostic trouble code (DTC) stored in one of the control modules in the high speed network, try to remedy the fault by downloading new software for the control module that stored the diagnostic trouble code (DTC)
3. The control module should be replaced as a last resort.

Other information

- see **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK (2005-2012)**
- Go to the tab software and program the control module with the latest software.

- **Continue**

  Refer to **VERIFICATION**

VERIFICATION

- Ignition on
- Wait for 20 seconds.

NOTE: **This first verification assumes that download of new software was required in the control module that generated the diagnostic trouble code. If download of new software was not required: read out diagnostic trouble codes and check if the code status is permanent or intermittent to learn how difficult it will be to find the fault.**

Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Check that the diagnostic trouble code (DTC) for faulty communication is not stored again.

Has the fault been remedied?

- **YES**

  Refer to **REPLACING THE CONTROL MODULE**

- **NO**

  Refer to **TAKING READING ON CABLE IN THE CAN NETWORK (HS-CAN)**

TAKING READING ON CABLE IN THE CAN NETWORK (HS-CAN)

Fig. 219: Identifying Ignition OFF

- Ignition off

- Disconnect the battery negative lead.
- Remove the central electronic module (CEM)
- Connect the breakout box to the cable harness for the central electronic module (CEM). Do not connect the central electronic module (CEM).

HINT: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

Disconnect the CAN network to make it easier to locate a fault. A suitable point to disconnect the network is at the central electronic module (CEM). Fault-tracing therefore starts from the central electronic module (CEM).

Take resistance readings across the following terminals. Various readings will be obtained due to the structure of the network. Twist the cable harness and work the connectors at accessible points along the cable harness in order to check whether the resistance changes during each measurement. This method can be used to detect intermittent short-circuits or open-circuits.

NOTE: The following resistance readings only measure the main arteries in the high speed network, not the junctions that exist for some control modules. See the appropriate service information for the relevant car model. If an open-circuit is suspected in a cable, or a short-circuit is suspected in one of its junctions, the connector at the control module for this junction must be disconnected and the reading taken from there.

Take the following readings

- Resistance between C3:47 and C3:48. Resistance should be 120 ohms.

  NOTE: Measuring will only give value 120 ohms if the main circuit in the CAN-net is intact. If there is a short-circuit somewhere in the CAN-net (either main circuit or other branching) the resistance will be 0 ohms.

- The resistance between C3:48 and a connection to voltage as well as between C3:48 and a short-circuit to ground. The resistance shall be very high (more than 1 Mohms).
- The resistance between C3:47 and a connection to voltage as well as between C3:47 and a short-circuit to ground. The resistance shall be very high (more than 1 Mohms).

HINT: Any short-circuit detected on the CAN-net may be on the main circuit or on any branching running out to some control modules. If a fault is found, try to disconnect the junction with the fault at a point further forward. Try to locate the fault in this way.

Remedy as necessary.

- Connect the central electronic module (CEM) to the breakout box
- Connect the battery.
- Ignition on

NOTE: **When the adapter cable harness and the central electronic module (CEM) have been connected, there is access to both sides of the CAN network (both LS-CAN and HS-CAN). There will also be traffic on both networks. Be careful to check the terminals between which the readings are to be taken so that the intended reading is not taken on the wrong network.**

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount

of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Check as follows:

- Measure the voltage between C3:48 and ground. The voltage shall be approx. 2.3 V.
- Measure the voltage between C3:47 and ground. The voltage shall be approx. 2.8 V.

Other information

- see **BATTERY, DISCONNECTING**

Is the value OK?

- **YES**

  Refer to **INFORMATION**

- **NO**

  Refer to **IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK**

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Check communication/load on HS-CAN by measuring voltage between C3:48 and C3:47. The voltage's average value shall be approx. 0.5 V (permitted is 0.4 to 0.6 V). In case of communication error, the voltage is approx. 0.7 V and higher.

In order to identify which control module is communicating incorrectly, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Continue until the voltage between the CAN cables drops to approximately 0.5 V.

HINT: When the suspected control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears. Ignition off between each check.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced.

NOTE: A faulty control module that disrupts communication can place other control modules in Limp-Home mode (i. e. they work but with limited functionality) even after switching the ignition off and on a number of times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

Remedy as necessary.

- **Continue**

  Refer to **VERIFICATION**

HINT: Once a fault has been repaired, conduct a verification to check that the fault has been remedied.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-U300362

Condition

NOTE: This trouble code is only relevant for troubleshooting and action in the following cases:

- The trouble code is active in the present driving cycle and has been active for a longer period of time.
- The customer experiences malfunction that can be attributed to the trouble code.

The Differential electronic module (DEM) continuously checks its power supply. The control module compares the power supply to the Central electronic module (CEM) to its own power supply. Information about the power supply to the Central electronic module (CEM) comes from the CAN network.

The diagnostic trouble code (DTC) is stored if the control module detects that:

- Voltage of differential electronic module (DEM) is 2 V lower than voltage to central electronic module (CEM).
- Incorrect value runs longer than 10 seconds.

The control module's test for the diagnostic trouble code (DTC) starts when:

- Data has been received from the central electronic module (CEM).

NOTE: The control module can only detect the fault once the test has been started and the diagnostic trouble code (DTC) is stored when the conditions are met.

FAULT-TRACING INFORMATION

Use the following information and general checks during fault-tracing.

NOTE: Check that the fuses are intact. For locations, see the instruction manual, cover for fuse box, fuse ratings or similar.

1. Check, if possible, relevant functions in the vehicle using buttons/controls/test drives to determine the status of the fault.

   NOTE: If the vehicle does not show any of the given symptoms in the diagnostic trouble code information (DTC), this may mean that the fault is intermittent or that the control module is not detecting the fault at this moment.

2. Use the diagnostic trouble code's **frozen values** , **status identifiers** and **counter** to determine the operating conditions when the fault was detected, the fault's current status and any degree of intermittence of the fault.
3. Check and fault-trace according to **the fault causes** that are specified in the **diagnostic trouble code (DTC) information** .
4. Use **VIDA (Volvo Scan Tool) Vehicle communication** . Read off the parameters, activate components and functions, carry out quick tests and checking routines for the diagnostic trouble codes to identify the fault.
5. Check relevant components according to **Component specifications** .
6. Check relevant signals using **wiring diagram** , **signal specification** and **breakout box** .

DESCRIPTION OF FROZEN VALUES

EXPLANATION

Frozen values are parameter values stored when a Diagnostic Trouble Code (DTC) is generated.

TOTAL MILEAGE, VALUE

The value indicates the total distance covered by the vehicle at the time the Diagnostic Trouble Code (DTC) was generated.

Measurement range: 0 -16, 777, 215 km.

MECU POWER SUPPLY, VALUE

The value indicates the voltage over the Central Electronic Module (CEM) when the Diagnostic Trouble Code (DTC) was generated.

Measurement range: 0 -64 V.

Normal range: 12.0 - 14.5 V.

OUTSIDE TEMPERATURE, VALUE

The value indicates the outside temperature at the time the Diagnostic Trouble Code (DTC) was generated.

Measurement range: -40 °C to +215 °C.

ENGINE STATUS

Indicates if the engine is running.

No = Engine off

Yes = Engine running

ENGINE START IN PROGRESS

Indicates if start attempt is in progress.

No = Engine not cranking

Yes = Engine cranking

ECU-TEMPERATURE

The value shows the temperature in Differential electronic module (DEM). The temperature sensor is located on the circuit board.

POWER SUPPLY, DIFFERENTIAL ELECTRONIC MODULE (DEM), VALUE

The value indicates the power supply to the Differential Electronic Module (DEM) when the Diagnostic Trouble Code (DTC) was generated.

Measurement range: 0 -25.5 V.

Normal range: 12.0 - 14.5 V.

WHEEL SPEED, VALUE

The value indicates the wheel speed when the Diagnostic Trouble Code (DTC) was generated.

Measurement range: 0 - 255 km/h.

POWER SUPPLY, PRESSURE REDUCING VALVE

The value displays the current through the pressure reducing valve.

Measurement range 0 - 4095 mA.

POWER SUPPLY, PUMP MOTOR

The value indicates the supply through the electrically driven feed pump when the Diagnostic Trouble Code (DTC) was generated.

Measurement range 0 - 8191 mA.

DEM STATUS

Indicates the status of the differential electronic module (DEM) (software related) when the diagnostic trouble code was stored.

OK = AOC unit (coupling) is operating normally.

Coupling fully open upon request = AOC unit (coupling) fully open (requested from Brake Control Module (BCM))

Coupling inactive or faulty (open) = AOC unit (coupling) is open due to a fault in the system.

Coupling closed = AOC unit (coupling) is closed due to a fault in the system.

AOC STATUS

Indicates the status of the Active on Demand Coupling when the diagnostic trouble code (DTC) was stored. The differential electronic module (DEM) obtains the signal from the brake control module (BCM). The signal is used to deactivate the Active on Demand Coupling during special driving conditions.

Normal operation = Request from the Brake Control Module (BCM) for the AOC unit (coupling) to operate normally.

Rapid opening = Request from the Brake Control Module (BCM) for the AOC unit (coupling) to open quickly.

Slow opening = Request from the Brake Control Module (BCM) for the AOC unit (coupling) to open slowly.

Error in BCM = An error has occurred in the Brake Control Module (BCM) which means that the Differential Electronic Module (DEM) opens the AOC unit (coupling).

Completely locked = Request from the brake control module (BCM) that the Active on Demand Coupling unit (clutch) should lock completely (maximum torque to the rear axle).

Torque limiting = Request from the brake control module (BCM) that the Active on Demand Coupling unit should limit the torque to the rear axle.

DIAGNOSTIC INFORMATION, STATUS

Indicates the diagnostic status of the differential electronic module (DEM) when the diagnostic trouble code (DTC) was stored.

No diagnostic trouble code (DTC) = No diagnostic trouble code (DTC) is stored in the control module.

At least one diagnostic trouble code (DTC) = At least one diagnostic trouble code (DTC) is stored in the control module.

All diagnostic tests have not been carried out = All diagnostic tests in the control module have not been carried out.

All diagnostic tests have been carried out = All diagnostic tests in the control module have been carried out

BRAKE PEDAL, STATUS

Indicates the stop lamp switch position, activated or not activated, when the diagnostic trouble code (DTC) was stored.

Active = Brake light switch actuated.

Not active = Stop lamp switch off.

PARKING BRAKE, STATUS

Indicates the parking brake position, activated or not activated, when the diagnostic trouble code (DTC) was stored.

Active = Parking brake actuated.

Not active = Parking brake not applied.

ABS STATUS

Indicates the status of ABS control when the diagnostic trouble code (DTC) was stored. The differential electronic module (DEM) obtains the value via the control area network (CAN) from the brake control module (BCM).

Active = ABS modulation.

Inactive = No ABS modulation.

GAUGE (HIGH OIL TEMPERATURE), VALUE.

The value indicates the number of times the Differential Electronic Module (DEM) has disengaged the all-wheel drive due to excessively high oil temperature.

Measurement range: 0-65, 534 times.

ENGINE SPEED, VALUE

The value indicates the engine speed when the Diagnostic Trouble Code (DTC) was generated.

Measurement range:0-8191 r/min.

Idle speed: approx. 750 r/min.

ENGINE TORQUE

The value indicates an engine control module (ECM)-calculated torque, supplied to the Active on Demand

Coupling input shaft (propeller shaft) when the diagnostic trouble code (DTC) was stored. Calculation includes the gear ratio of the transmission and the final drive. The differential electronic module (DEM) obtains the value via the controller area network (CAN) from the engine control module (ECM).

Measurement range: -16.376 Nm to +16.384 Nm.

REAR AXLE TORQUE, VALUE

The value indicates the torque transferred to the rear axle, calculated by the AOC unit (coupling) when the Diagnostic Trouble Code (DTC) was generated.

Measurement range: 0 -8191 Nm

REQUESTED ENGINE TORQUE

The value indicates the requested engine torque of the driver when the diagnostic trouble code (DTC) was stored. The differential electronic module (DEM) uses this information to correctly transfer torque to the rear axle.

Measurement range: -16.376 Nm to +16.375 Nm.

DESCRIPTION OF STATUS IDENTIFIER

Status identifier
There are different status identifiers that can be read out for each diagnostic trouble code (DTC). The control module tests each connection more or less continuously. By reading out the diagnostic trouble code (DTC) and the associated status identifier (which detects the malfunction and stores the DTC), information about the test is obtained. Not all status identifiers need to be implemented in one control module, this varies from system to system. All status identifiers are reset and start counting again each time the control module is powered up and when erasing diagnostic trouble codes (DTCs). The possible status identifiers are described below.

Status identifier	**Explanation**
SI#01	The malfunction is validated now. Shows if the control module detects the malfunction right now. It is only when the test is in progress that the control module can detect malfunction and generate diagnostic trouble code.
SI#02	The malfunction is validated in the current operating cycle. Shows if the control module has detected the malfunction any time during this operating cycle.
SI#03	Intermittent not yet confirmed diagnostic trouble code.
SI#04	Confirmed diagnostic trouble code.
SI#05	Test status in current and/or earlier operating cycle. Shows if control module has performed test for this diagnostic trouble code in current and/or earlier operating cycle.
SI#06	The malfunction is validated in an earlier operating cycle. Shows if the control module has detected the malfunction any time during an earlier operating cycle.
SI#07	Test status in current operating cycle. Shows if control module has performed test

	for this diagnostic trouble code in current operating cycle.
SI#08	Request activate warning light/text message. Information about the diagnostic trouble code activates a warning light or text message.

DESCRIPTION OF COUNTER

Counter
There are eight different counters that are stored individually for each diagnostic trouble code (DTC). For an intermittent malfunction, the values of the different counters can be studied to determine how intermittent the malfunction is. All counters do not need to be implemented in one control module, this varies from system to system. The possible counters are described below.

Counter	**Function**
C#1	Counts the number of operating cycles since the malfunction was *last* validated. This information can be used to determine whether the malfunction is active during the current operating cycle or not. The malfunction is present now if the value is zero.
C#2	Counts the number of operating cycles since the malfunction was *last* validated, where test for the diagnostic trouble code was performed without the malfunction being detected and validated. When a test is performed, no malfunction is detected, the counter will count up by 1 for each operating cycle.
C#3	Counts the number of operating cycles since the malfunction was validated *the first time* . For each completed operating cycle the counter will count up by 1.
C#4	Counts the number of operating cycles in which the malfunction was validated since it was first validated. Counts the number of times the malfunction has occurred since the first time.
C#5	Counts the number of warm-up cycles since the MIL-light has gone off.
C#6	The counter counts the number of internal detections of the malfunction that have been performed for the diagnostic trouble code. When this counter reaches + 127, the control module considers that the malfunction is active right now. When counter is at value -127 the malfunction is not active. The value is reset to zero at each new operating cycle. If the value increases toward +127 the control module has detected a malfunction and, for each internal test, the value counts up. When the malfunction is not active, the control module counts down to minimum -127. Value can only be changed when the control module has started the test for the diagnostic trouble code. The increments with which the control module counts up or down the value may vary between control modules.
C#7	Shows maximum value for current operating cycle.
C#8	Shows maximum value for current and/or earlier operating cycle.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION DEM-U300362

Condition

NOTE: **This trouble code is only relevant for troubleshooting and action in the following cases:**

- The trouble code is active in the present driving cycle and has been active for a longer period of time.
- The customer experiences malfunction that can be attributed to the trouble code.

Fig. 231: Active On Demand Coupling Control Module
Courtesy of VOLVO CARS CORPORATION

The Differential Electronic Module (DEM) checks its power supply by comparing the voltage of the Differential Electronic Module (DEM) with that of the Central Electronic Module (CEM). If the control module registers a difference which exceeds 2.0 V, the fault code is set.

The trouble code may be diagnosed after 10 seconds with the ignition on.

Substitute Value

- Four wheel drive is disengaged.

Possible Source

Signal too high:

- Faulty power supply to the Central Electronic Module (CEM).

Signal too low:

- Connector resistance and oxidation in the connectors.

Fault symptom[s]

- Four wheel drive is not functioning.

FAULT TRACING

FAULT-TRACING INFORMATION

NOTE: This trouble code is only relevant for troubleshooting and action in the following cases:

- The trouble code is active in the present driving cycle and has been active for a longer period of time.
- The customer experiences malfunction that can be attributed to the trouble code.

In other cases, the DTC does not indicate a fault and must therefore be ignored and only erased.

Do you want to continue fault-tracing?

- **YES**

  Refer to **CHECKING THE STATUS**

CHECKING THE STATUS

Fig. 232: Identifying Ignition ON
Courtesy of VOLVO CARS CORPORATION

- Ignition on

  Read the values of voltage supply to the Differential Electronic Module (DEM) and the Central Electronic Module (CEM).

  The two voltage levels should not differ by more than +/- 2.0 V.

  HINT: Compare with the battery voltage.

  If the voltage supply to the Differential electronic module (DEM) differs by more than 2.0 V from that of the Central Electronic Module (CEM), a permanent fault is indicated.

  If the voltage is correct, this indicates that the fault has existed previously but is not active just now (an

intermittent fault).

- Ignition off
- Reinstall the connectors, components etc.
- Ignition on

  Read the value of the supply voltage to the Differential Electronic Module (DEM).

  Check that the value is appropriate. The voltage should not differ by more than +/- 2.0 V from that of the Central Electronic Module (CEM).

see **9985972**

see **9997057**

NOTE: **As the illustrations in this service information are used for different model years and / or models, some variation may occur. However, the essential information is always correct.**

REMOVAL

PREPARATIONS

NOTE: **Check that the parking brake is not applied and that the gear selector is in position P or in gear.**

Ignition off

Position the rear lifting arms so that they do not obstruct the front brackets securing the rear axle arms to the body.

REMOVING DRIVE SHAFTS

Remove the drive shafts on both sides according to: **DRIVE SHAFT REAR, REPLACING**.

REMOVING THE SPARE WHEEL AND REAR SECTION OF THE EXHAUST SYSTEM

Fig. 54: Identifying Rear Section Of Exhaust System & Spare Wheel
Courtesy of VOLVO CARS CORPORATION

Remove the rear section of the exhaust system and the spare wheel.

Support the rear edge of the three-way catalytic converter (TWC) so as not to put strain on the exhaust manifold.

Remove the propeller shaft from the final drive and the member for the center bearing. See **PROPELLER SHAFT** .

REMOVING THE SCREWS FOR THE CENTER BEARING MEMBER AND PROPELLER SHAFT

Tie up the shaft.

Use the rear cross member as support.

Remove one screw and slacken off the other. Turn out the member.

REMOVING THE CABLE HARNESS

Fig. 55: Active On Demand Coupling Control Module Cable Harness
Courtesy of VOLVO CARS CORPORATION

Remove the connector from the Differential Electronic Module (DEM).

Detach the cable harness from the final drive housing and the mounting in the rear axle member.

Fold the cable harness to one side to prevent damage when removing the final drive.

REMOVING THE FINAL DRIVE

Fig. 56: Identifying Rear Axle Member Cover, Front Mounting Screws & Final Drive Housing Screws
Courtesy of VOLVO CARS CORPORATION

Remove:

- the cover for the rear axle member
- the screw for the front mounting for the final drive housing.

Slacken off the 2 rear screws for the rear axle member/final drive housing. Leave the screws in place by a few threads.

REMOVING THE REAR AXLE MEMBER

Fig. 57: Identifying Front Mounting Screws & Portable Jack Tool Attachment (998 5972)
Courtesy of VOLVO CARS CORPORATION

Bring see **9985972** into light contact with the front section of the rear axle member.

Remove the screws from the front mounting in the body for the rear axle member, on both sides.

Carefully lower the frame. Remove the jack.

REMOVING THE FINAL DRIVE HOUSING

Fig. 58: Identifying Final Drive Housing & Screws
Courtesy of VOLVO CARS CORPORATION

Support the final drive housing. Remove the two loose screws.

Lift out the final drive housing from the rear axle member. Position the final drive housing on a workbench.

INSTALLATION

NOTE: For tightening torques, see: TIGHTENING TORQUE.

NOTE: To ensure that there is no exhaust leakage, see: FLANGED JOINT, ASSEMBLING .

INSTALLING THE REAR AXLE MEMBER

Fig. 59: Identifying Front Mounting Screws & Portable Jack Tool Attachment (998 5972)
Courtesy of VOLVO CARS CORPORATION

Install the final drive housing in the rear axle member. Loosely secure the final drive housing to the rear bushings in the frame using screws.

Bring see **9985972** into light contact with the front section of the rear axle member.

Install:

- the screws for the front mounting in the body for the rear axle member, on both sides.
- the 2 x M12 screws for the bracket/body. Tighten.
- the M14 screw for the bracket, the rear axle frame and body. Tighten. See: **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS** .

Remove see **9985972** .

INSTALLING THE FINAL DRIVE HOUSING

Fig. 60: Identifying Rear Axle Member Cover, Front Mounting Screws & Final Drive Housing Screws
Courtesy of VOLVO CARS CORPORATION

Install:

- 1 M12 front screw for the final drive housing. Tighten
- the cover for the rear axle member using 4 M12 screws. Tighten
- the 2 x rear M12 screws for the subframe/final drive housing. Tighten.

INSTALLING THE CABLE HARNESS

Fig. 61: Active On Demand Coupling Control Module Cable Harness
Courtesy of VOLVO CARS CORPORATION

Connect the connector for the differential electronic module (DEM). Install the cable harness in the mounting in the rear axle member.

Install the propeller shaft on the final drive. Install the member for the center bearing. See: **PROPELLER SHAFT** .

INSTALLING DRIVE SHAFTS

Install the drive shafts on both sides according to: **DRIVE SHAFT REAR, REPLACING**.

INSTALLING THE SPARE WHEEL AND REAR SECTION OF THE EXHAUST SYSTEM

Fig. 62: Identifying Rear Section Of Exhaust System & Spare Wheel
Courtesy of VOLVO CARS CORPORATION

Check that the gasket for the flanged joint between the front and rear exhaust pipe is not damaged. Replace if necessary.

Install the rear cross member. Use 2 x M8 screws. Tighten.

FILLING AND CHECKING THE OIL LEVEL

Fig. 63: Filling And Checking The Oil Level
Courtesy of VOLVO CARS CORPORATION

Top up and check the oil level in the active on demand coupling (AOC).

Use oils, see: **LUBRICANT TRANSMISSION**

Tighten both the level plugs. See: **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**.

Top up and check the oil level in the rear axle gear.

Use oils, see: **LUBRICANT TRANSMISSION**

Tighten both the level plugs. See: **TIGHTENING TORQUE**.

OIL PUMP, FOUR WHEEL DRIVE COUPLING

PREPARATORY WORK

REMOVING COMPONENTS

Remove the following items:

- the propeller shaft. See **PROPELLER SHAFT**
- the flange from the four wheel drive coupling. See **ACTIVE ON-DEMAND COUPLING SEAL**.

REMOVING THE OIL PUMP

Ignition off

NOTE: Thoroughly clean around the oil pump before beginning removal.

Fig. 64: Locating Oil Pump Connector And Screws
Courtesy of VOLVO CARS CORPORATION

Place a container under the active on demand coupling (AOC).

Remove:

- the connector from the Differential Electronic Module (DEM) to the active on demand coupling (AOC)
- the cable harness mountings.

Remove the two screws from the oil pump. Pull the pump straight out from the active on demand coupling (AOC).

NOTE: Later versions of the oil pump have the socket for the cable harness on the side of the oil pump housing. The cable harness is shorter. This version supersedes all previous versions, including as a replacement part.

INSTALLING

NOTE: For tightening torques, see TIGHTENING TORQUE.

INSTALLING OIL PUMP

Fig. 65: Identifying Oil Pump Seat
Courtesy of VOLVO CARS CORPORATION

Thoroughly check that the oil pump seat in the active on demand coupling (AOC) is clean. There must be no residue left from cloths or paper.

Fig. 66: Identifying Oil Pump And O-Rings
Courtesy of VOLVO CARS CORPORATION

Check that the new O-rings are in position. Lubricate the O-rings. Use oil for the active on demand coupling (AOC). See: **LUBRICATION TRANSMISSION** .

Fig. 67: Locating Oil Pump Connector And Screws
Courtesy of VOLVO CARS CORPORATION

Install the oil pump. Press the pump in as far as possible. Lightly tighten the 2 M5 screws alternately. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**.

Connect the connector.

FILLING AND CHECKING THE OIL LEVEL

Top up and check the oil level in the active on demand coupling (AOC), the front level plug.

Use oil. See: **LUBRICATION TRANSMISSION** .

Tighten the level plug according to: **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC**

COMPONENTS.

Install the propeller shaft and the exhaust system. See **FINAL DRIVE, REPLACING**.

TEMPERATURE AND PRESSURE SENSOR, FOUR-WHEEL DRIVE CLUTCH

PREPARATORY WORK

Ignition off

Wait 3-4 minutes after switching the ignition off to reduce oil leakage at removal.

REMOVING THE DIFFERENTIAL ELECTRONIC MODULE (DEM)

Fig. 68: Active On Demand Coupling Control Module Screws
Courtesy of VOLVO CARS CORPORATION

CAUTION: Clean the area around the control module thoroughly before beginning removal.

Place a container under the active on demand coupling (AOC). Disconnect the connectors to the control module and the oil pump.

Remove:

- the 2 x screws for the control module
- the control module together with the seal plate and the cupped washer.

REMOVING THE COMPONENTS FROM THE ACTIVE ON DEMAND COUPLING (AOC)

Fig. 69: Choke Valve And Temperature/Pressure Sensor
Courtesy of VOLVO CARS CORPORATION

CAUTION: Make sure that no damage is caused when removing the throttle valve. The valve cannot be replaced separately. The throttle valve is removed in order to be installed in the control module. This is done to minimize the risk of damage occurring to the contacts when installing.

Remove the throttle valve and temperature/pressure sensor from the coupling.

A = Throttle valve.

B = Temperature / pressure sensor.

To remove, use large pliers. Grasp the end of the throttle valve, hold the pliers steady and pull the valve straight out.

Remove:

- temperature-/pressure sensor as above
- The O-ring from the throttle valve seat in the coupling housing.

NOTE: For tightening torques. See TIGHTENING TORQUE.

Install:

- Differential electronic module (DEM)
- the seal plate
- the washer
- the throttle plate with the O-rings

- temperature-/pressure sensor with the O-rings
- the screws.

The O-ring for the throttle valve seat is installed separately.

PLACING THE SEALING PLATE IN THE CONTROL MODULE

Fig. 72: Active On Demand Coupling Control Module Kit
Courtesy of VOLVO CARS CORPORATION

Place the sealing plate in the control module

Press the throttle valve and the temperature-/pressure sensor into place on the control module connector. Place the cupped washer with the convex side against the temperature-/pressure sensor.

Lubricate the sealing rings on the valves. Use oil. See: **LUBRICATION TRANSMISSION** .

INSTALLING THE O-RING

Fig. 73: Active On Demand Coupling Control Module O-Ring
Courtesy of VOLVO CARS CORPORATION

Carefully check that the control module sealing surface and the valve seats in the Active on Demand Coupling (AOC) are clean, there must be no residue left from cloths or paper.

Lubricate the new O-ring using oil. See: **LUBRICATION TRANSMISSION** and securely press into its seat.

INSTALLING THE ACTIVE ON DEMAND COUPLING (AOC)

Fig. 74: Installing Control Module For Active On Demand Coupling
Courtesy of VOLVO CARS CORPORATION

Install the control module with the valves for the coupling, hold it pressed against the coupling housing while installing the 2 x screws. Lightly tighten alternately.

Fig. 75: Active On Demand Coupling Control Module Screws
Courtesy of VOLVO CARS CORPORATION

Tighten, see: **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**.

Connect the connectors for the control module and the oil pump.

Top up and check the oil level in the active on demand coupling (AOC). See: **FINAL DRIVE, REPLACING**.

Erase any diagnostic trouble codes (DTCs).

Push forward the final drive slightly, to create space at the front of the bushing.

Mark up the bushing with a line as illustrated, it is extremely important that the bushing is install in the right position.

Place the bushing and tool as illustrated

Exercise care to center the tool, tighten the nut on the puller rod and press in the bushing.

Check that the threaded rod goes through the front punch completely, so that a full thread is obtained.

Centre the tools against the bushing and sub-frame and tighten the nut on the puller rod.

NOTE: The marking on the bushing should face downward.

The bushing is in the correct position when the flange on see **9997334** rests on see **9997333** when the tool is pressed together.

Install:

- Differential electronic module (DEM)
- the seal plate
- the washer
- the throttle plate with the O-rings

- temperature-/pressure sensor with the O-rings
- the screws.

The O-ring for the throttle valve seat is installed separately.

PLACING THE SEALING PLATE IN THE CONTROL MODULE

Fig. 101: Active On Demand Coupling Control Module Kit
Courtesy of VOLVO CARS CORPORATION

Place the sealing plate in the control module

Press the throttle valve and the temperature-/pressure sensor into place on the control module connector. Place the cupped washer with the convex side against the temperature-/pressure sensor.

Lubricate the sealing rings on the valves. Use oil. See: **LUBRICANT TRANSMISSION** .

INSTALLING THE O-RING

Fig. 102: Active On Demand Coupling Control Module O-Ring
Courtesy of VOLVO CARS CORPORATION

Carefully check that the control module sealing surface and the valve seats in the Active on Demand Coupling (AOC) are clean, there must be no residue left from cloths or paper.

Lubricate the new O-ring using oil. See: **LUBRICANT TRANSMISSION** and securely press into its seat.

INSTALLING THE ACTIVE ON DEMAND COUPLING (AOC)

Fig. 103: Installing Control Module For Active On Demand Coupling
Courtesy of VOLVO CARS CORPORATION

Install the control module with the valves for the coupling, hold it pressed against the coupling housing while installing the 2 x screws. Lightly tighten alternately.

Fig. 104: Active On Demand Coupling Control Module Screws

REMOVAL

PREPARATORY WORK

Remove the final drive. See: **FINAL DRIVE, REPLACING** .

REMOVING THE BUSHING

Fig. 105: Removing The Bushing
Courtesy of VOLVO CARS CORPORATION

Position the final drive in stand see **9992250** and fixture see **9995297** with corresponding screws, marked with 1 on the screw head.

When removing the bushing use puller cylinder see **9512564** or see **9995575** with corresponding pump see **9995576** .

Position connecting rod see **9995588** in the puller cylinder and sleeve 7078-2 against the puller cylinder and the bushing. Position counterhold see **9997078** with washer 7078-1. Turn the counterhold so that the cut out is against the radius on the final drive housing and so that it is supported on the cast surrounding surface.

Press out the bushing

INSTALLATION

MARKING THE BUSHING AND THE FINAL DRIVE HOUSING

Fig. 106: Identifying Bushing And Final Drive Housing Marks
Courtesy of VOLVO CARS CORPORATION

In order to obtain the correct position of the bushing during installation, make a mark opposite the cut out in the edge of the bushing and straight down the side.

Make a mark opposite the edge, between the cast surface and the machined surface on the final drive housing, as illustrated.

Place the bushing marking opposite the marking on the final drive housing.

INSTALLING THE FINAL DRIVE HOUSING

Fig. 107: Installing The Final Drive Housing
Courtesy of VOLVO CARS CORPORATION

Use puller cylinder see **9512564** alternatively see **9995575** with corresponding pump see **9995576** .

Position connecting rod see **9995589** in the puller cylinder and counterhold see **9997078** against the puller cylinder and the bushing final drive housing. Turn the counterhold so that cut out is against the radius on the final drive housing and so that it is supported on the cast surrounding surface.

Lubricate the end of the bushing and outer sleeve. Use a small amount of petroleum jelly. Position washer 7078-1 with the flat side against the bushing and lightly install the connecting rod. Turn the bushing to the correct position, as above. Press the bushing so that the flange on the bushing is against the final drive housing.

FINISHING

Install the final drive. See: **FINAL DRIVE, REPLACING** .

OIL PUMP ACTIVE ON DEMAND COUPLING (AOC), REPLACING

NOTE: As the illustrations in this service information are used for different model years and / or models, some variation may occur. However, the essential information is always correct.

PREPARATORY WORK

REMOVING COMPONENTS

Remove:

- the propeller shaft and the exhaust system. See: **FINAL DRIVE, REPLACING**
- the flange from the active on demand coupling (AOC). See: **PINION SEAL COUPLING (AOC), REPLACING**.

REMOVAL

REMOVING THE OIL PUMP

Ignition off

NOTE: Thoroughly clean around the oil pump before beginning removal.

Fig. 108: Locating Oil Pump Connector And Screws
Courtesy of VOLVO CARS CORPORATION

Place a container under the active on demand coupling (AOC).

Remove:

- the connector from the Differential Electronic Module (DEM) to the active on demand coupling (AOC)
- the cable harness mountings.

Remove the two screws from the oil pump. Pull the pump straight out from the active on demand coupling (AOC).

NOTE: Later versions of the oil pump have the socket for the cable harness on the side of the oil pump housing. The cable harness is shorter. This version supersedes all previous versions, including as a replacement part.

INSTALLATION

NOTE: For tightening torques, see TIGHTENING TORQUE.

INSTALLING OIL PUMP

Fig. 109: Identifying Oil Pump Seat
Courtesy of VOLVO CARS CORPORATION

Thoroughly check that the oil pump seat in the active on demand coupling (AOC) is clean. There must be no residue left from cloths or paper.

Fig. 110: Identifying Oil Pump And O-Rings
Courtesy of VOLVO CARS CORPORATION

Check that the new O-rings are in position. Lubricate the O-rings. Use oil for the active on demand coupling (AOC). See: **LUBRICATION TRANSMISSION** .

Fig. 111: Locating Oil Pump Connector And Screws
Courtesy of VOLVO CARS CORPORATION

Install the oil pump. Press the pump in as far as possible. Lightly install the 2 x M5 screws for the pump alternately. Tighten. See: **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**.

Connect the connector.

FILLING AND CHECKING THE OIL LEVEL

Top up and check the oil level in the active on demand coupling (AOC), the front level plug.

Use oil. See: **LUBRICATION TRANSMISSION** .

Tighten the level plug according to: **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC**

COMPONENTS.

Install the propeller shaft and the exhaust system. See: **FINAL DRIVE, REPLACING**.

REMOVING THE FLANGE

Fig. 112: Identifying Removal Of Flange Nut With Counterhold 999 5652 And Adapter 999 7058
Courtesy of VOLVO CARS CORPORATION

Remove the flange nut. Use counterhold see **9995652** together with adapter see **9997058** . Mark up the flange in

relation to the end of the shaft.

Place a container under the active on demand coupling (AOC).

Fig. 113: Identifying Removal Of Flange With 999 5893
Courtesy of VOLVO CARS CORPORATION

Remove the flange. If the flange is stuck, use puller see **9995893** .

Fig. 114: Removing Flange Using 999 5893 (2 Of 2)
Courtesy of VOLVO CARS CORPORATION

NOTE: **For cars with a vibration damper on the Active on Demand Coupling (AOC) flange.**

Use 55 mm long screws for the puller. The oil pump may be damaged if too long screws are used.

Check that the sealing surfaces of the flange are free of faults. Replace the flange with a new one if there is a fault.

REMOVING THE SEAL

Fig. 115: Identifying Removal Of Seal From Active On Demand Coupling Using Extractor 999 5069
Courtesy of VOLVO CARS CORPORATION

Remove the Active on Demand Coupling (AOC). Use puller see **9995069** .

Thoroughly check that no seal residue remains.

INSTALLATION

INSTALLING THE SEAL

Fig. 116: Identifying Installation Of Seal Using Drift 999 7025
Courtesy of VOLVO CARS CORPORATION

Lubricate the new seal. Use oil for the active on demand coupling (AOC). See: **LUBRICATION TRANSMISSION**

Use drift see **9997025** when installing. Tap in the seal until the head of the drift is against the active on demand coupling (AOC) housing.

INSTALLING THE FLANGE

Fig. 117: Identifying Installation Of Flange Using 999 5652 And 999 7058
Courtesy of VOLVO CARS CORPORATION

Install the flange for the active on demand coupling (AOC) according to the previous mark (if the old flange is used).

Install a new nut for the shaft/flange. Use counterhold see **9995652** with adapter see **9997058** .

Tighten the nut. See: **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**.

INSTALLING THE PROPELLER SHAFT AND EXHAUST SYSTEM

Install the propeller shaft and the exhaust system. See: **FINAL DRIVE, REPLACING** .

FILLING AND CHECKING THE OIL LEVEL

Fig. 118: Identifying Final Drive (Front & Rear) Level Plugs
Courtesy of VOLVO CARS CORPORATION

Top up and check the oil level in the active on demand coupling (AOC), the front level plug.

Use oil. See: **LUBRICATION TRANSMISSION** .

Tighten the level plug according to: **TIGHTENING TORQUE**.

PINION SEAL FINAL DRIVE, REPLACING

Special tools:

see **9997023**

see **9997024**

NOTE: As the illustrations in this service information are used for different model years and / or models, some variation may occur. However, the essential information is always correct.

REMOVAL

REMOVING THE EXHAUST SYSTEM AND PROPELLER SHAFT

Remove the propeller shaft and the exhaust system. See: **FINAL DRIVE, REPLACING** .

REMOVING THE ACTIVE ON DEMAND COUPLING

Remove the Active on Demand Coupling (AOC). See **REMOVING THE ACTIVE ON DEMAND COUPLING**.

REMOVING THE PINION SEAL

Fig. 119: Identifying Removal Of Pinion Seal Using Extractor 999 7023
Courtesy of VOLVO CARS CORPORATION

The seal consists of two parts.

Use extractor see **9997023** .

NOTE: The screw and inner socket in the extractor must be unscrewed when tapping on the extractor.

Tap the tool onto the seal so that the flat end is against the seal. Tighten the inner socket. Counter hold the outer part at the same time so that the tool expands against the seal.

Remove the seals using the screw in the extractor.

Check that no seal residue is left in the final drive.

If the inner section of the seal remains in place, tap in the extractor again and pull out the inner section.

NOTE: Do not knock in the extractor too hard. This can damage in the extractor, which in turn can scratch the mating surface on the pinion shaft.

NOTE: Check that no seal residue is left in the final drive.

INSTALLATION

INSTALLING THE PINION SEAL

Fig. 120: Identifying Installation Of Pinion Seal Using Drift 999 7024
Courtesy of VOLVO CARS CORPORATION

The seal consists of two sections but is installed as one unit.

Lubricate the edge of the seal. Use oil for the (AOC). See: **LUBRICATION TRANSMISSION** .

Use drift see **9997024** for installation. Position the section of the seal with the largest outer diameter against the

drift. Tap in the seal until the head of the drift is against the final drive housing.

INSTALLING THE ACTIVE ON DEMAND COUPLING (AOC)

Install the active on demand coupling (AOC). See: **INSTALLING THE ACTIVE ON DEMAND COUPLING (AOC)**.

INSTALLING THE PROPELLER SHAFT AND EXHAUST SYSTEM

Install the propeller shaft and the exhaust system. See: **FINAL DRIVE, REPLACING** .

REFILLING THE OIL IN THE FINAL DRIVE

Fig. 121: Identifying Final Drive (Front & Rear) Level Plugs
Courtesy of VOLVO CARS CORPORATION

Top up and check the oil level in the active on demand coupling (AOC) (the front level plug) and in the final drive (the rear level plug).

Use oils, see: **LUBRICATION TRANSMISSION** .

Tighten the level plugs according to: **TIGHTENING TORQUE**.

When removing the bushing, use puller cylinder see **9512564** or see **9995575** and associated pump see **9995576** .

Place connecting rod see **9995588** in the puller cylinder and sleeve 7078-2 against the puller cylinder and the bushing. Position counterhold see **9997078** and washer 7078-1, turn the counterhold so that the cut-out is facing the radius of the final drive housing and so that it is supported on the surrounding cast surface.

Press out the bushing

INSTALLATION

MARKING THE BUSHING AND FINAL DRIVE HOUSING

Fig. 131: Identifying Bushing And Final Drive Housing Marks

To achieve the correct position of the bushing when installing.

Make a mark directly opposite the cut-out in the edge of the bushing and straight down the side.

Make a mark directly opposite the edge that is formed between the cast surface and the machined surface on the final drive housing, as illustrated.

Position the mark on the bushing directly opposite the mark on the final drive housing.

INSTALLING THE FINAL DRIVE HOUSING

Fig. 132: Installing The Final Drive Housing

Courtesy of VOLVO CARS CORPORATION

Use puller cylinder see **9512564** or see **9995575** and associated pump see **9995576** .

Position connecting rod see **9995589** in the puller cylinder and counterhold see **9997078** against the puller cylinder and final drive housing, turn the counterhold so that the cut-out is facing the radius of the final drive housing and so that it is supported on the surrounding cast surface.

Lubricate the end of the bushing and the outer sleeve with a little petroleum jelly, position washer 7078-1 with the flat side against the bushing and gently apply the nut for the connecting rod. Turn the bushing to the correct position as above. Press the bushing into place so that the flange on the bushing is against the final drive housing.

FINISHING

Install the final drive. See **FINAL DRIVE, REPLACING**.

DIFFERENTIAL ELECTRONIC MODULE (DEM), REPLACING

NOTE: As the illustrations in this service information are used for different model years and / or models, some variation may occur. However, the essential information is always correct.

PREPARATORY WORK

Ignition off.

Wait 3-4 minutes after the ignition is switched off to minimize oil leakage on removal.

REMOVAL

REMOVING THE DIFFERENTIAL ELECTRONIC MODULE (DEM)

NOTE: Clean the area around the control module thoroughly before beginning removal.

Fig. 133: Active On Demand Coupling Control Module Screws

Position a container underneath the Active on Demand Coupling.

Disconnect the connectors for the control module and the oil pump.

Remove:

- the 2 screws for the control module
- the control module with the sealing plate and the cupped washer.

REMOVING COMPONENTS FROM THE ACTIVE ON DEMAND COUPLING

Fig. 134: Choke Valve And Temperature/Pressure Sensor
Courtesy of VOLVO CARS CORPORATION

Remove the choke valve and the temperature/pressure sensor from the coupling.

A = choke valve.

B = temperature/pressure sensor.

To remove, grasp the end of the choke valve. Use a large pliers. Hold the pliers steady. Pull the valve straight out.

Remove:

- the temperature/pressure sensor as above
- The O-ring from the choke valve seat in the Active on Demand Coupling housing.

INSTALLATION

INSTALLING RELEVANT COMPONENTS

Fig. 135: Active On Demand Coupling Components

Press the choke valve and temperature/pressure sensor into place on the control module contacts.

Place the cupped washer with the convex side against the temperature/pressure sensor.

Lubricate the sealing rings on the valves with oil, P/N 116 1641-4 (0.3 liters).

INSTALLING THE O-RING

Fig. 137: Active On Demand Coupling Control Module O-Ring
Courtesy of VOLVO CARS CORPORATION

Carefully check that the mating surface for the control module and the valve seats in the Active on Demand Coupling are clean. There must be no lint or traces of paper or rags.

Lubricate the new O-ring with oil, P/N 116 1641-4 (0.3 liters). Press the O-ring into place in its seat.

INSTALLING THE CONTROL MODULE FOR THE ACTIVE ON DEMAND COUPLING

Remove the rear section of the exhaust system and the spare wheel.

Support the rear edge of the three-way catalytic converter (TWC) so as not to put strain on the exhaust manifold.

Pay attention to the following when removing propeller shaft

NOTE: Applies to 6-cylinder engines only.

Follow instructions. See **PROPELLER SHAFT, SPECIAL INFORMATION**

Remove the propeller shaft from the final drive. Remove the member for the center bearing. See **PROPELLER SHAFT, REPLACING** .

REMOVING THE SCREWS FOR THE PROPELLER SHAFT/CENTER BEARING MEMBER

Tie up the shaft.

Use the rear cross member as support.

Remove one screw and slacken off the other. Turn out the member.

REMOVING THE CABLE HARNESS

Install the final drive housing in the rear axle member. Loosely secure the final drive housing to the rear bushings in the frame using screws.

Bring the jack into light see **9985972** contact under the front section of the rear axle member.

Install the screws in the front mounting for the rear axle member in the body on both sides.

Install the 2 M12 screws for the bracket/body.

Tighten.

Install the screw for the bracket/rear axle member/body, 1 x M12 or 1 x M14 (2005-). Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS** .

Remove the mobile jack.

INSTALLING THE FINAL DRIVE HOUSING

Fig. 146: Identifying Rear Axle Member Cover, Front Mounting Screws & Final Drive Housing Screws
Courtesy of VOLVO CARS CORPORATION

Install:

- 1 M12 front screw for the final drive housing. Tighten
- the cover for the rear axle member using 4 M12 screws. Tighten
- the 2 rear M12 screws for the sub-frame/final drive housing. Tighten.

INSTALLING THE CABLE HARNESS

Fig. 147: Active On Demand Coupling Control Module Cable Harness
Courtesy of VOLVO CARS CORPORATION

Connect the connector to the control module for the differential electronic module (DEM). Install the cable harness in the mounting in the rear axle member.

Install the propeller shaft on the final drive. Install the member for the center bearing. See **PROPELLER SHAFT, REPLACING** .

INSTALLING DRIVE SHAFTS

FILLING AND CHECKING THE OIL LEVEL

Fig. 149: Identifying Final Drive (Front & Rear) Level Plugs
Courtesy of VOLVO CARS CORPORATION

Fill and check oil in the clutch (AOC). The front level plug is for the clutch (AOC). Only use oil with part number 116 1641 (0.3 liter container)

Fill the final drive with oil. Check the oil level. The rear level plug is for the final drive. Only oil P/N 116 1620-

8 (1 liter containers) may be used

Tighten both level plugs. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**.

Position a container underneath the Active on Demand Coupling.

Remove:

- the connector from the Differential Electronic Module (DEM) for the oil pump for the Active on Demand Coupling
- the cable harness mountings.

Remove the 2 screws for the oil pump. Pull the pump straight out of the Active on Demand Coupling.

NOTE: Later versions of the oil pump have the socket for the cable harness on the side of the oil pump housing. The cable harness is shorter. This version supersedes all previous versions, including as a replacement part.

INSTALLATION

NOTE: For tightening torques, see TIGHTENING TORQUE.

INSTALLING THE OIL PUMP

Fig. 151: Identifying Oil Pump Seat
Courtesy of VOLVO CARS CORPORATION

Thoroughly check that the oil pump seat in the Active on Demand Coupling is clean. There must not be any lint from paper or cloths.

Fig. 152: Identifying Oil Pump And O-Rings
Courtesy of VOLVO CARS CORPORATION

Check that the new O-rings are in position. Lubricate the O-rings using oil for the Active on Demand Coupling, P/N 116 1641 (1 liter container).

Fig. 153: Locating Oil Pump Connector And Screws
Courtesy of VOLVO CARS CORPORATION

Install the oil pump. Press the pump in as far as possible. Lightly tighten the 2 M5 screws alternately. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**.

Connect the connector.

FINISHING

Fill the AOC (Active on Demand Coupling) with oil. Check the oil level. See **ACTIVE ON DEMAND COUPLING (AOC), REPLACING**.

Install the propeller shaft and the exhaust system. See **FINAL DRIVE, REPLACING**.

REMOVAL

REMOVING THE EXHAUST SYSTEM

Remove the exhaust system. See **FINAL DRIVE, REPLACING** .

REMOVING THE PROPELLER SHAFT

Remove the propeller shaft from the flange for Active on Demand Coupling. See **FINAL DRIVE, REPLACING** .

REMOVING THE FLANGE

Fig. 154: Identifying Removal Of Flange Nut With Counterhold 999 5652 And Adapter 999 7058
Courtesy of VOLVO CARS CORPORATION

Remove the nut for the flange. Use counterhold see **9995652** with adapter see **9997058** . Mark the flange in relation to the end of the shaft.

Position a container underneath the Active on Demand Coupling.

Remove the flange. If the flange is stuck on the shaft, use puller see **9995893** .

Fig. 155: Identifying Removal Of Flange With 999 5893
Courtesy of VOLVO CARS CORPORATION

Check that the flange mating surface is free of defects. If not, replace the flange.

REMOVING THE SEAL

Fig. 156: Identifying Removal Of Seal From Active On Demand Coupling Using Extractor 999 5069
Courtesy of VOLVO CARS CORPORATION

Remove the seals from the Active on Demand Coupling. Use extractor see **9995069** .

Check thoroughly that no seal residue remains.

INSTALLATION

NOTE: For tightening torques, see TIGHTENING TORQUE.

INSTALLING THE SEAL

Fig. 157: Identifying Installation Of Seal Using Drift 999 7025
Courtesy of VOLVO CARS CORPORATION

Lubricate the new seal using oil for the Active on Demand Coupling, P/N 116 1641 (1 liter pack).

Use drift see **9997025** for installation. Tap the seal into place until the surface of the drift is against the housing for Active on Demand Coupling.

INSTALLING THE FLANGE

Fig. 158: Identifying Installation Of Flange Using 999 5652 And 999 7058
Courtesy of VOLVO CARS CORPORATION

Install the flange on the AOC (Active on Demand Coupling) using the previous markings (if using the old flange).

Install a new nut on the shaft - flange. Use counterhold see **9995652** with adapter see **9997058** .

Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**.

Fill the AOC (Active on Demand Coupling) with oil. Check the oil level.

- For AW50AWD and 4T65AWD 2003-, see **ACTIVE ON DEMAND COUPLING (AOC), REPLACING**
- For M66AWD 2004-, see **ACTIVE ON DEMAND COUPLING (AOC), REPLACING** .

INSTALLING THE PROPELLER SHAFT

Install the propeller shaft. See **FINAL DRIVE, REPLACING** .

INSTALLING THE EXHAUST SYSTEM

Install the exhaust system. See **FINAL DRIVE, REPLACING** .

PINION SEAL FINAL DRIVE, REPLACING

Special tools:

see **9997023**

see **9997024**

NOTE: **As the illustrations in this service information are used for different model years and / or models, some variation may occur. However, the essential information is always correct.**

REMOVAL

REMOVING THE ACTIVE ON DEMAND COUPLING

Remove the Active on Demand Coupling.

- For AW50AWD and 4T65AWD 2003-, see **ACTIVE ON DEMAND COUPLING (AOC), REPLACING** .
- For M66AWD 2004-, see **ACTIVE ON DEMAND COUPLING (AOC), REPLACING** .

REMOVING THE PINION SEAL

Fig. 159: Identifying Removal Of Pinion Seal Using Extractor 999 7023
Courtesy of VOLVO CARS CORPORATION

The seal consists of two parts.

Use extractor see **9997023** .

NOTE: The screw and inner socket in the extractor must be unscrewed when tapping on the extractor.

Tap the tool onto the seal so that the flat end is against the seal. Tighten the inner socket. Counter hold the outer part at the same time so that the tool expands against the seal.

Remove the seals using the screw in the extractor.

Check that no seal residue is left in the final drive.

If the inner part of the seal remains in place, tap in the extractor again and pull out the inner part.

NOTE: Do not knock in the extractor too hard. This can damage in the extractor, which in turn can scratch the mating surface on the pinion shaft.

Check that no seal residue is left in the final drive.

INSTALLATION

INSTALLING THE PINION SEAL

Fig. 160: Identifying Installation Of Pinion Seal Using Drift 999 7024
Courtesy of VOLVO CARS CORPORATION

The seal consists of 2 sections but is installed as one unit.

Lubricate the lip of the seal using oil for the Active on Demand Coupling, P/N 116 1641 (1 liter pack).

Use drift see **9997024** for installation. Position the section of the seal with the largest outer diameter against the drift. Tap in the seal until the head of the drift is against the final drive housing.

Install the Active on Demand coupling.

- For AW50AWD and 4T65AWD 2003-, see **ACTIVE ON DEMAND COUPLING (AOC), REPLACING**
- For M66AWD 2004-, see **ACTIVE ON DEMAND COUPLING (AOC), REPLACING** .

Fill with oil and check the level.

REFILLING THE OIL IN THE FINAL DRIVE

Top up the oil in the final drive and check the level. See **FINAL DRIVE, REPLACING** .

DRIVE SHAFT, CV JOINT (B5254T2, AW55-50/51SN; 2004-2007)

BOOT CV JOINT HOUSING, REPLACING

Special tools:

see **9512619**

DISASSEMBLY

NOTE: **Preparatory work, left-hand side: See REPLACING THE FRONT LEFT DRIVE SHAFT. Preparatory work, right-hand side: See REPLACING THE FRONT RIGHT DRIVE SHAFT.**

NOTE: **The inner constant velocity joint must not be split.**

REMOVING THE BOOT

Fig. 161: Identifying Drive Shaft Held In Soft Jawed Vice
Courtesy of VOLVO CARS CORPORATION

Secure the drive shaft in a vice with soft jaws.

Remove the clamps from the boots.

Cut the boot and remove it from the shaft.

CHECKING THE MEASUREMENTS

Fig. 162: Identifying Distance From Inner Ring To Inner Groove On Shaft
Courtesy of VOLVO CARS CORPORATION

Wipe off the grease from the constant velocity joint housing.

Measure the distance from the inner ring to the inner groove on the shaft. Note the measurement.

REMOVING THE CONSTANT VELOCITY JOINT HOUSING

Fig. 163: Identifying Brass Drift & Constant Velocity Joint Housing
Courtesy of VOLVO CARS CORPORATION

Tap off the constant velocity joint housing.

Use a brass drift.

NOTE: Only tap the inner ring. Take care not to damage the bearing race or outer ring.

CLEANING THE CONSTANT VELOCITY JOINT HOUSING

The joint can be cleaned when assembled. See **CLEANING THE CONSTANT VELOCITY JOINT HOUSING - CONTINUED**.

If the joint needs to be disassembled, see **CLEANING / CHECKING THE OUTER CONSTANT VELOCITY JOINT**.

CLEANING THE CONSTANT VELOCITY JOINT HOUSING - CONTINUED

Fig. 164: Clamp From Inner Gaiter

Thoroughly clean off any dirt and grease from the joint. Blow the joint dry.

For greasing/assembling, see **ASSEMBLY**.

WHEN REPLACING THE INNER BOOT

Remove the clamps from the inner boot. Cut the boot and remove it from the shaft.

NOTE: Clean and blow the inner constant velocity joint dry while assembled.

For greasing/assembling, see **ASSEMBLY**.

CLEANING / CHECKING THE OUTER CONSTANT VELOCITY JOINT

MARKING THE CONSTANT VELOCITY JOINT

Fig. 165: Identifying Mark On Outer Ring Of Outer Constant Velocity Joint, Ball Holder And Inner Ring
Courtesy of VOLVO CARS CORPORATION

Mark the outer ring, bearing race and inner ring on the outer constant velocity joint.

Mark components in relation to each other.

Use an electric scriber.

REMOVING THE CONSTANT VELOCITY JOINT BALL BEARINGS

Fig. 166: Identifying Inner Joint Ring And Ball Holder
Courtesy of VOLVO CARS CORPORATION

Remove the ball bearings.

Turn the constant velocity joint inner ring and bearing race. Remove the ball bearings clockwise one by one.

Use the marking as the starting point when removing. See **MARKING THE CONSTANT VELOCITY JOINT**.

Place the ball bearings in order so that they can be reinstalled in the same positions.

REMOVING THE BEARING RACE AND INNER RING

Fig. 167: Identifying Ball Holder And Inner Ring From Shaft
Courtesy of VOLVO CARS CORPORATION

Remove the bearing race and the inner ring from the shaft.

Turn the inner ring 90 degrees in relation to the bearing race.

Remove the inner ring.

CLEANING CONSTANT VELOCITY JOINT COMPONENTS

Fig. 168: Constant Velocity Joint Components
Courtesy of VOLVO CARS CORPORATION

Wash the constant velocity joint components thoroughly.

NOTE: Replace the drive shaft assembly if any component has cracking or wear damage. Scratches and minor pitting of the bearing races are permitted.

INSTALLING THE INNER RING

Fig. 169: Identifying Inner Ring & Ball Holder
Courtesy of VOLVO CARS CORPORATION

Install the inner ring in the bearing race.

Line up the markings with each other. Install a ball bearing.

NOTE: Note the position of the ball bearings.

Turn the inner ring and the bearing race.

Install the balls one by one in the same positions as before. See **REMOVING THE CONSTANT VELOCITY JOINT BALL BEARINGS**.

ASSEMBLY

LUBRICATING THE CONSTANT VELOCITY JOINT

Fig. 170: Identifying Constant Velocity Joint
Courtesy of VOLVO CARS CORPORATION

Lubricate the constant velocity joint thoroughly.

Apply grease behind the joint via the shaft hole in the inner ring.

Use half of the grease packet. The remainder will be used later in the gaiter. See **ASSEMBLING THE DRIVE SHAFT BOOT**.

INSTALLING THE SNAP RING

Fig. 171: Installing New Lock Ring
Courtesy of VOLVO CARS CORPORATION

Replace the snap ring.

Install the new snap ring included in the boot kit.

INSTALLING BOOTS AND THE CONSTANT VELOCITY JOINT

Fig. 172: Installing New Gaiters On Drive Shaft
Courtesy of VOLVO CARS CORPORATION

Install:

- the new boot(s) on the drive shaft
- the constant velocity joint on the drive shaft.

Ensure that inner ring is straight in the constant velocity joint.

Tap on the constant velocity joint. Use a rubber mallet.

Check that the lock ring is seated in its groove. Do this by measuring the distance. See **CHECKING THE MEASUREMENTS**.

ASSEMBLING THE DRIVE SHAFT BOOT

Fig. 173: Applying Grease In Boot
Courtesy of VOLVO CARS CORPORATION

Apply grease in the boot.

Apply the remaining grease from, see **LUBRICATING THE CONSTANT VELOCITY JOINT**.

NOTE: Ensure that there is no grease on the mating surfaces between the boot and the constant velocity joint and the shaft.

Remove excess grease. Use methylated spirit.

Ensure that the boot is in position on the constant velocity joint housing.

Install a new clamp. Use pliers see **9512619** .

VENTING THE BOOT

Fig. 174: Inserting Screwdriver Between Drive Shaft And Gaiter
Courtesy of VOLVO CARS CORPORATION

Venting is carried out to remove any over pressure in the boot. Use a rounded screwdriver.

Carefully insert the screwdriver between the drive shaft and boot. Ensure that the boot is in position on the drive shaft.

Ensure that the boot is aligned against the inner rib on the drive shaft.

Install a new clamp. Use pliers see **9512619** .

Install the drive shafts

For the left-hand side , see **REPLACING THE FRONT LEFT DRIVE SHAFT**.

For the right-hand side , see **REPLACING THE FRONT RIGHT DRIVE SHAFT**.

Fig. 175: Spraying Wax On Outer Gaiter

WARNING: **Do not use magnets or magnetic tools close to tooth wheels, drive shafts or wheel hubs. A magnetized tooth wheel will lose its function and generate incorrect signals resulting in fault codes.**

NOTE: **Any magnetized tooth wheel, drive shaft or wheel hub must be replaced with a new component.**

PREPARATORY WORK

DRAINING OIL

NOTE: Only applies to cars with 4T65AWD transmissions.

Drain the transmission fluid. See **REPLACING THE BEVEL GEAR/CHAIN HOUSING** .

Drain the transmission fluid, for 4T65AWD, see **REPLACING THE PINION SEAL FOR THE BEVEL GEAR** .

REMOVAL

REMOVING THE BALL JOINT FROM THE CONTROL ARM

Fig. 176: Locating Drive Shaft Nut And Lower Ball Joint Nut
Courtesy of VOLVO CARS CORPORATION

Remove:

- the wheel
- the screw for the drive shaft. Counterhold using a screwdriver in the brake disc vents. Tap/press the end of the drive shaft into the hub approximately 20-25 mm
- the nut for the ball joint / control arm. If the ball joint pinion moves, counterhold the end of the lug. Use a torx wrench.

REMOVING THE BALL JOINT FROM THE CONTROL ARM, CONTINUED

Fig. 177: Disconnecting Ball Joint Pinion From Control Arm Using 999 7062
Courtesy of VOLVO CARS CORPORATION

Disconnect the ball joint pinion from the control arm. Use tool see **9997062** .

Install cap nut 7062-1 on the ball joint pinion. Tighten the nut against the control arm. Then turn back one turn to form a gap between the cap nut and the control arm.

Position the extractor on the control arm. Detach the ball joint from the control arm.

REMOVING THE DRIVE SHAFT FROM THE WHEEL HUB

Fig. 178: Identifying Wheel Knuckle, Special Tools 999 7076 And 999 5562
Courtesy of VOLVO CARS CORPORATION

Unhook the control arm from the ball joint pinion.

Pull the control arm down. Use lever see **9997076** to move the wheel spindle to the side. At the same time, install protective sleeve see **9995562** on the ball joint pinion. Hold the sleeve in place using the nut for the ball joint.

Remove the drive shaft from the hub.

NOTE: Only applies to cars with M66AWD transmissions.

Remove the splash guard under the engine.

DRAINING TRANSMISSION FLUID

Fig. 181: Identifying Transmission Drain Plug
Courtesy of VOLVO CARS CORPORATION

NOTE: Only applies to cars with M66AWD transmissions.

Collect the oil in a container.

Remove the drain plug. Drain the oil. Install the plug with a new gasket. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**.

REMOVING THE DRIVE SHAFT FROM THE TRANSMISSION

Fig. 182: Identifying Drive Shaft & Transmission
Courtesy of VOLVO CARS CORPORATION

NOTE: Only applies to cars with AW55-50 or AW50AWD transmissions.

Use jimmy bar see **9995462** B.

Turn the constant velocity joint housing so that the jimmy bar is as far into the joint as possible.

Remove the drive shaft from the transmission. Ensure that the end of the drive shaft does not damage the seal.

REMOVING THE DRIVE SHAFT FROM THE TRANSMISSION, CONTINUED

Fig. 183: Identifying Drive Shaft, Transmission & Tool 999 5462

NOTE: Applies only to vehicles with M66AWD transmissions and drive shafts with a tripod joint.

Position the two tools opposite each other. Detach the drive shaft.

NOTE: Cars with Cross-grove drive shaft joints and M66AWD transmissions. Use jimmy bar see 9995462 B as above.

Remove the drive shaft from the transmission. Ensure that the end of the drive shaft does not damage the seal.

INSTALLATION

INSTALLING THE DRIVE SHAFT IN THE TRANSMISSION

Fig. 184: Drive Shaft Mating Surface
Courtesy of VOLVO CARS CORPORATION

NOTE: Only applies to cars with 4T65AWD transmissions.

Lubricate the drive shaft mating surface.

Use oil P/N 116 1521-8 (1 liter container).

Press the drive shaft into the transmission. Check that the snap ring is in the groove on the transmission by pulling the constant velocity joint.

NOTE: Only applies to cars with M66AWD transmissions.

Lubricate the drive shaft mating surface.

Use oil P/N 116 1745 (1 liter container).

Press the drive shaft into the transmission. Check that the snap ring is in the groove on the transmission by pulling the constant velocity joint.

NOTE: Do not pull the drive shaft as the axial pinions cannot support large loads.

INSTALLING THE DRIVE SHAFT ON THE WHEEL HUB

Fig. 185: Locating Drive Shaft Nut And Lower Ball Joint Nut
Courtesy of VOLVO CARS CORPORATION

Lubricate the drive shaft splines for the wheel hub. Use a small amount of oil.

Hold down the control arm as when removing. Align the drive shaft in the hub.

Remove the guard from the ball joint. Align the ball joint lug in the control arm.

Install a new lock nut on the ball joint. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS** .

NOTE: Counterhold the end of the ball joint whilst tightening so that the boot does not twist. Use a Torx wrench.

Install a new screw for the drive shaft/wheel hub. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS** .

FILLING WITH OIL

NOTE: Only applies to cars with M66AWD transmissions.

Top up with new oil. See **TRANSMISSION FLUID, REPLACING**.

INSTALLING THE SPLASH GUARD

Lubricate the lip of the new seal using wheel bearing grease, P/N 116 1251 (400 g).

Use tool see **9995591** .

NOTE: **It is important that the seal is positioned correctly. The positions differ between the left and right-hand sides. See below.**

POSITIONING THE SEALS

Fig. 205: Positioning The Seals
Courtesy of VOLVO CARS CORPORATION

Tap in the seals to the correct depth between the drift and the final drive housing.

NOTE: **There are different depths for the left and right-hand sides between the flange of the drift and the final drive housing.**

Left side: the measurement (A) must be **0.5 mm** ; measured from the surface of the hooks on the nut.

Right-hand side: the dimension (B) must be **6 mm** . The seal must be flush with the housing surface.

INSTALLING THE DRIVE SHAFT

To install drive shafts, see **DRIVE SHAFT REAR, REPLACING**.

FILLING AND CHECKING THE OIL LEVEL

Top up and check the oil level in the final drive. See **FINAL DRIVE, REPLACING**.

PREPARATIONS

Fig. 206: Identifying Dip Stick Pipe & Oil Suction Device
Courtesy of VOLVO CARS CORPORATION

Drain approximately 4 liters of fluid from the transmission. Use an oil suction unit.

Remove the dip stick. Ensure that the suction pipe reaches down into the transmission.

Extract approximately 4 liters of oil.

REMOVING THE DRIVE SHAFT

Remove the drive shaft. See **REPLACING THE FRONT LEFT DRIVE SHAFT**.

REMOVING THE DRIVE SHAFT SEAL

Fig. 207: Removing Drive Shaft Seal Using Puller 999 5731
Courtesy of VOLVO CARS CORPORATION

Use puller see **9995731** .

Unscrew the puller. Install a hook gradually between the shaft and sealing ring.

Secure the hooks to the puller. Tighten them using the screws.

Install the mounting bracket and the nut.

Extract the sealing ring.

NOTE: Check carefully that no residue from the old seal is left in the transmission.

INSTALLING THE DRIVE SHAFT SEAL

Fig. 208: Installing Drive Shaft Seal Using Drift 999 5730 And Shaft 999 1801
Courtesy of VOLVO CARS CORPORATION

NOTE: Clean thoroughly before installing the new seal.

Lubricate the seal lip using ATF oil, P/N 116 1521, (1 liter containers).

Use drift see **9995730** and shaft see **9991801** .

Carefully tap the drive shaft seal in until the drift is in contact with the transmission housing.

INSTALLING THE DRIVE SHAFT

Install the drive shaft according to **REPLACING THE FRONT LEFT DRIVE SHAFT**.

FILLING WITH TRANSMISSION FLUID

Top up the transmission with new oil, using the same quantity that was drained.

NOTE: Only ATF oil, P/N 116 1521, may be used (1 liter containers).

Check the oil level. See **OIL LEVEL, CHECKING**

NOTE: Clean thoroughly before installing the new seal.

Lubricate the seal lip using ATF oil, P/N 116 1521, (1 liter containers).

Use drift see **9997063** and shaft see **9991801** .

Carefully tap the drive shaft seal in until the drift is in contact with the chain housing.

INSTALLING THE DRIVE SHAFT

Install the drive shaft according to **REPLACING THE FRONT RIGHT DRIVE SHAFT**.

FILLING WITH TRANSMISSION FLUID

Top up the transmission with new oil, using the same quantity that was drained.

NOTE: Only ATF oil, P/N 116 1521, may be used (1 liter containers).

Check the oil level. See **OIL LEVEL, CHECKING** .

REMOVAL

HINT: The methods displays replacement on the left-hand side but is identical to the right-hand side.

REMOVING WHEELS

Raise the car.

Remove the wheel.

PREPARATORY WORK

Push the suspension up to the specified measurement to detach the screwed joint between the control arms/struts, see **TENSIONER 999 5659, USER INSTRUCTIONS** .

DISCONNECTING THE STUB AXLE

Fig. 212: Identifying Rear Suspension Assembly, Nuts & Screws
Courtesy of VOLVO CARS CORPORATION

Push up the rear suspension using tension calliper see **9995659** 500 mm between the wing edge and the center of the wheel hub.

Remove:

- the handbrake cable from the mounting in the track rod
- the screw for the drive shaft - wheel hub (1)
- the screw for the track rod mounting (2)
- the screw for the control arm mounting (3)
- the nut for the anti-roll bar link mounting (4). Counterhold using a Torx spanner so that the boot does not rotate
- the screw for the lateral link mounting (5).

REMOVING THE DRIVE SHAFT FROM THE WHEEL HUB

Fig. 213: Identifying Wheel Spindle & Mobile Jack Attachment

Install jack see **9985972** under the stub axle and raise carefully.

NOTE: Pull out the drive shaft from the wheel hub whilst raising the stub axle. Angle the shaft past the stub axle.

Release the tensioner so that the control arm hangs in the shock absorber.

REMOVING THE DRIVE SHAFT FROM THE FINAL DRIVE HOUSING

Fig. 214: Identifying Screwdriver In Constant Velocity Joint Housing & Final Drive Housing
Courtesy of VOLVO CARS CORPORATION

Use a large screwdriver. Position the screwdriver tip between the constant velocity joint housing and the final drive housing.

Tap firmly so that the snap ring for the drive shaft releases. Pull out the drive shaft. Do not damage the drive shaft seal.

Install sealing plug see **9997060** .

INSTALLATION

NOTE: For tightening torques, see TIGHTENING TORQUE.

INSTALLING THE DRIVE SHAFT IN THE FINAL DRIVE HOUSING

Fig. 215: Identifying Drive Shaft Mating Surface, Snap Ring & Final Drive
Courtesy of VOLVO CARS CORPORATION

Lubricate the drive shaft mating surface using P/N 116 1329-6 (0.5 liter container).

Press the drive shaft into the final drive housing. Check that the snap ring is in the groove in the final drive.

Check by pulling the constant velocity joint on the drive shaft.

INSTALLING THE DRIVE SHAFT ON THE WHEEL HUB

Fig. 216: Identifying Rear Suspension Assembly, Nuts & Screws
Courtesy of VOLVO CARS CORPORATION

Lubricate the drive shaft splines using a small amount of oil.

Position the drive shaft in the wheel hub. Carefully lower the mobile jack.

Remove the mobile jack.

Press up the control arm and tensioner to the previous specified measurement so that the screws can be

installed.

NOTE: **After installing the screws, press tension calliper see 9995659 up to the normal position, see TENSIONER 999 5659, USER INSTRUCTIONS , before tightening the screws**

Install:

- 1 M12 screw for the lateral link mounting (5). Tighten
- 1 M12 nut for the lateral link mounting (4). Tighten. Counterhold using a Torx spanner so that the boot does not rotate
- 1 M12 screw for the lateral link mounting (3). Tighten
- 1 M12 screw for the track rod mounting (2). Tighten
- 1 M10 screw to the drive shaft - wheel hub (1). Tighten
- the handbrake cable and mounting for the track rod.

Remove the tensioner.

- the bevel gear according to **BEVEL GEAR, REPLACING**
- the circlip in the connecting socket.

CARRY OUT CORRECTIVE ACTION AT WORN SPLINES IN THE SLEEVE

Fig. 218: Identifying Pressing Cardboard Disc Against The Seal
Courtesy of VOLVO CARS CORPORATION

Cut out a O40 mm cardboard disc and use it to prevent shavings entering the gearbox. Apply a thick bead of grease or petroleum jelly on the seal in the sleeve. Press the cardboard disc against the seal.

Fig. 219: Identifying Grinding A Groove Inside Of The Sleeve
Courtesy of VOLVO CARS CORPORATION

Grind a groove in the inside of the sleeve to enable the expander see **9995777** to get a hold.

The sleeve can also be heated using a hot air gun or induction heater.

INSTALLING TOOL

Fig. 220: Identifying Expander 999 5777, Puller Rod 999 5777 And Extractor 999 5777
Courtesy of VOLVO CARS CORPORATION

Install expander 5777-1 and connecting rod 5777-2 (these are included in extractor 999 5777) on the puller cylinder.

Puller cylinder see **9995575** is used together with hydraulic pump see **9995576** (foot-operated). Alternatively tool see **9992615** can be used, which consists of a puller cylinder and a compressed-air driven hydraulic pump.

REMOVING THE CONNECTING SOCKET

Fig. 221: Identifying Sleeve 999 5777
Courtesy of VOLVO CARS CORPORATION

Place a container underneath the gearbox. Ensure that the piston rod in the puller cylinder is in the outer position.

Position sleeve see **9995777** between the puller cylinder and the transmission. Press in the expander so that it enters the groove on the connecting sleeve.

Apply the puller cylinder. Check that the socket between the gearbox and the puller cylinder is in contact with its support surfaces.

Remove the socket.

REMOVING THE SEALING RING FROM THE GEARBOX

Fig. 222: Identifying Drift 999 5779
Courtesy of VOLVO CARS CORPORATION

Use a screwdriver to pry out the seal.

Position drift see **9995779** on the end of the differential to protect the sealing face from damage when removing the seal. Do not damage the surfaces in the transmission housing.

REMOVING THE SEALING RING FROM THE CONNECTING SOCKET

Fig. 223: Identifying Tapping Sealing Ring Out Of Socket Using Screwdriver

Courtesy of VOLVO CARS CORPORATION

Use a screwdriver to tap the sealing ring out of the socket.

Check the mating surface for the connecting socket. The socket must be replaced if there are signs of grooves or corrosion.

INSTALLING THE CONNECTING SOCKET

Fig. 224: Installing Connecting Socket
Courtesy of VOLVO CARS CORPORATION

Heat the sleeve to 150°-175°C in an oven and place the sleeve in drift see **9995778** . Set it against the transmission and tap in the sleeve until contacts the differential.

The above operation must be carried out quickly to prevent the heat spreading to the differential and causing the differential to expand.

Control measurement: the distance from the end of the connecting socket to the flat surface outside the sealing ring seat on the gearbox housing must be approximately 41 mm.

NOTE: Use protective gloves when handling the heated socket.

Care must be also taken to prevent burns in the remaining operations.

INSTALLING THE SEALING RING FOR THE CONNECTING SOCKET

Fig. 225: Identifying Installation Of Sealing Ring 999 5780
Courtesy of VOLVO CARS CORPORATION

Lubricate the sealing ring lip and the mating surface on the socket. Use ATF fluid.

Insert the seal ring to the sleeve. Tap the sleeve into place with drift see **9995780** . Tap in the drift until it contacts the transmission housing.

INSTALLING THE SEALING RING FOR THE DIFFERENTIAL

Fig. 226: Identifying Installation Of Sealing Ring For Differential
Courtesy of VOLVO CARS CORPORATION

Position locating pin 5779-1 in the end of the differential. Lubricate the sealing ring lip and the locating pin using ATF oil. Tap in the seal using drift see **9995779** . Tap the drift in until it is contact with the end of the connecting sleeve.

Install the circlip for the connecting socket.

FINISHING

Install the bevel gear according to **BEVEL GEAR, REPLACING**

Secure the drive shaft in a vice with soft jaws.

Remove the clamps from the boots.

Cut the boot and remove it from the shaft.

CHECKING THE MEASUREMENTS

Fig. 253: Identifying Distance From Inner Ring To Inner Groove On Shaft
Courtesy of VOLVO CARS CORPORATION

Wipe off the grease from the constant velocity joint housing.

Measure the distance from the inner ring to the inner groove on the shaft. Note the measurement.

REMOVING THE CONSTANT VELOCITY JOINT HOUSING

Fig. 254: Identifying Brass Drift & Constant Velocity Joint Housing

Courtesy of VOLVO CARS CORPORATION

Tap off the constant velocity joint housing.

Use a brass drift.

NOTE: Only tap the inner ring. Take care not to damage the bearing race or outer ring.

CLEANING THE CONSTANT VELOCITY JOINT HOUSING

The joint can be cleaned when assembled. See **CLEANING THE CONSTANT VELOCITY JOINT HOUSING - CONTINUED**.

If the joint needs to be disassembled, see **CLEANING / CHECKING THE OUTER CONSTANT VELOCITY JOINT**.

CLEANING THE CONSTANT VELOCITY JOINT HOUSING - CONTINUED

Fig. 255: Clamp From Inner Gaiter

Thoroughly clean off any dirt and grease from the joint. Blow the joint dry.

For greasing/assembling, see **ASSEMBLY**.

NOTE: Inner bellows may not be serviced.

For greasing/assembling, see **ASSEMBLY**.

CLEANING / CHECKING THE OUTER CONSTANT VELOCITY JOINT

MARKING THE CONSTANT VELOCITY JOINT

Fig. 256: Identifying Mark On Outer Ring Of Outer Constant Velocity Joint, Ball Holder And Inner Ring
Courtesy of VOLVO CARS CORPORATION

Mark the outer ring, bearing race and inner ring on the outer constant velocity joint.

Mark components in relation to each other.

Use an electric scriber.

REMOVING THE CONSTANT VELOCITY JOINT BALL BEARINGS

Fig. 257: Identifying Inner Joint Ring And Ball Holder
Courtesy of VOLVO CARS CORPORATION

Remove the ball bearings.

Turn the constant velocity joint inner ring and bearing race. Remove the ball bearings clockwise one by one.

Use the marking as the starting point when removing. See **MARKING THE CONSTANT VELOCITY JOINT**.

Place the ball bearings in order so that they can be reinstalled in the same positions.

REMOVING THE BEARING RACE AND INNER RING

Fig. 258: Identifying Ball Holder And Inner Ring From Shaft
Courtesy of VOLVO CARS CORPORATION

Remove the bearing race and the inner ring from the shaft.

Turn the inner ring 90 degrees in relation to the bearing race.

Remove the inner ring.

CLEANING CONSTANT VELOCITY JOINT COMPONENTS

Fig. 259: Constant Velocity Joint Components
Courtesy of VOLVO CARS CORPORATION

Wash the constant velocity joint components thoroughly.

NOTE: Replace the drive shaft assembly if any component has cracking or wear

damage. Scratches and minor pitting of the bearing races are permitted.

INSTALLING THE INNER RING

Fig. 260: Identifying Inner Ring & Ball Holder
Courtesy of VOLVO CARS CORPORATION

Install the inner ring in the bearing race.

Line up the markings with each other. Install a ball bearing.

NOTE: Note the position of the ball bearings.

Turn the inner ring and the bearing race.

Install the ball bearings one by one in the same positions as before. See **REMOVING THE CONSTANT VELOCITY JOINT BALL BEARINGS**.

ASSEMBLY

LUBRICATING THE CONSTANT VELOCITY JOINT

Fig. 261: Identifying Constant Velocity Joint
Courtesy of VOLVO CARS CORPORATION

Lubricate the constant velocity joint thoroughly.

Apply grease behind the joint via the shaft hole in the inner ring.

Use half of the grease packet. The remainder will be used later in the boot. See **ASSEMBLING THE DRIVE SHAFT BOOT**.

INSTALLING THE SNAP RING

Fig. 262: Installing New Lock Ring
Courtesy of VOLVO CARS CORPORATION

Replace the snap ring.

Install the new snap ring included in the boot kit.

INSTALLING BOOTS AND THE CONSTANT VELOCITY JOINT

Fig. 263: Installing New Gaiters On Drive Shaft
Courtesy of VOLVO CARS CORPORATION

Install:

- the new boot(s) on the drive shaft
- the constant velocity joint on the drive shaft.

Ensure that inner ring is straight in the constant velocity joint.

Tap on the constant velocity joint. Use a rubber mallet.

Check that the snap ring is seated in its groove. Do this by measuring the distance. See **CHECKING THE MEASUREMENTS**.

ASSEMBLING THE DRIVE SHAFT BOOT

Fig. 264: Applying Grease In Boot
Courtesy of VOLVO CARS CORPORATION

Apply grease in the boot.

Apply the remaining grease from, see **LUBRICATING THE CONSTANT VELOCITY JOINT**.

NOTE: Ensure that there is no grease on the mating surfaces between the boot and the constant velocity joint and the shaft.

Remove excess grease. Use methylated spirit.

Ensure that the boot is in position on the constant velocity joint housing.

Install a new clamp. Use see **9512619** .

VENTING THE BOOT

Fig. 265: Inserting Screwdriver Between Drive Shaft And Gaiter
Courtesy of VOLVO CARS CORPORATION

Venting is carried out to remove any over pressure in the boot. Use a rounded screwdriver.

Carefully insert the screwdriver between the drive shaft and boot. Ensure that the boot is in position on the drive shaft.

Ensure that the boot is aligned against the inner rib on the drive shaft.

Install a new clamp. Use see **9512619** .

Install the drive shafts

Push up the rear end with: see **9995659** to a measurement of **500 mm** between the fender's edge and the center of wheel hub.

Remove:

- the handbrake cable from the mounting in the track rod
- the screw for the drive shaft - wheel hub (1)
- the screw for the track rod mounting (2)
- the screw for the control arm mounting (3)
- the nut for the anti-roll bar link mounting (4). Counterhold using a Torx spanner so that the boot does not rotate

- the screw for the lateral link mounting (5).

Use see **9997160** . Drive out the shaft with a distinct blow.

NOTE: The tool is used as a wedge.

Install: see **9997060** .

INSTALLATION

NOTE: For tightening torques, see: TIGHTENING TORQUE.

INSTALLING THE DRIVE SHAFT IN THE FINAL DRIVE HOUSING

Fig. 272: Identifying Drive Shaft Mating Surface, Snap Ring & Final Drive
Courtesy of VOLVO CARS CORPORATION

NOTE: Always replace the drive shaft snap ring with a new one.

Lubricate the mating surfaces of the drive shaft. Use final drive oil. See **LUBRICANT TRANSMISSION**

Securely press the drive shaft into the final drive housing. Check that the snap ring is in the groove in the final drive by pulling the constant velocity joint on the drive shaft.

INSTALLING THE DRIVE SHAFT ON THE WHEEL HUB

Fig. 273: Identifying Rear Suspension Assembly, Nuts & Screws
Courtesy of VOLVO CARS CORPORATION

Lubricate the drive shaft splines using a small amount of oil.

Position the drive shaft in the wheel hub. Carefully lower the mobile jack.

Remove the mobile jack.

Press up the control arm and tensioner to the previous specified measurement so that the screws can be installed.

NOTE: After installing the screws, press see 9995659 up to normal position, see: TENSIONER 999 5659, USER INSTRUCTIONS , before tightening the screws

Install:

- 1 M12 screw for the lateral link mounting (5). Tighten
- 1 M12 nut for the lateral link mounting (4). Tighten. Counterhold using a Torx spanner so that the boot does not rotate
- 1 M12 screw for the lateral link mounting (3). Tighten
- 1 M12 screw for the track rod mounting (2). Tighten
- 1 M10 screw to the drive shaft - wheel hub (1). Tighten
- the handbrake cable and mounting for the track rod.

Remove the tensioner.

NOTE: Replace the sealing ring if it is damaged or worn.

Clean around the constant velocity joint before installing the sealing ring.

Carefully install the sealing ring. Ensure that the sealing ring is correctly positioned on the drive shaft.

FINISHING

Install the right-hand drive shaft. See: **DRIVE SHAFT RIGHT, REPLACING**. Install the left-hand drive shaft. See: **DRIVE SHAFT LEFT, REPLACING**.

DRIVESHAFT CONSTANT VELOCITY JOINT (B6324S, TF-80SC; 2007-2010)

BOOT CV JOINT HOUSING, INNER

Special tools:

see **9995519**

see **9512619**

see **9997161**

REMOVAL

CAUTION: The constant velocity joint housing must not be disassembled.

REMOVING DRIVE SHAFTS

Remove drive shafts: **DRIVE SHAFT LEFT, REPLACING** and **DRIVE SHAFT RIGHT, REPLACING**.

REMOVING THE BOOT

Fig. 290: Identifying Clamps On Boot
Courtesy of VOLVO CARS CORPORATION

Secure the drive shaft in a vise with soft jaws.

Remove:

- the clamps on the boot
- the boot.

Wipe off any grease.

MEASURING THE TRIPOD FOR THE CONSTANT VELOCITY JOINT HOUSING.

Fig. 291: Identifying Removal Of Constant Velocity Joint Housing
Courtesy of VOLVO CARS CORPORATION

Mark up the position of the tripod in relation to the constant velocity joint housing.

Remove the constant velocity joint housing by tapping the edge by the rollers so that the rollers detach, one at a time.

Use nylon or wooden shims.

REMOVING SNAP RING

Fig. 292: Identifying Snap Ring On Constant Velocity Joint Housing
Courtesy of VOLVO CARS CORPORATION

Wipe away any grease from the constant velocity joint housing.

Remove the snap ring for the constant velocity joint housing.

NOTE: When replacing old components, mark the tripod position in relation to the drive shaft.

REMOVING THE CV JOINT HOUSING

Remove the constant velocity joint housing. Use see **9997161** .

Do not hit the rollers.

REMOVING THE BOOT ON THE OUTER CONSTANT VELOCITY JOINT HOUSING

Fig. 293: Identifying Drive Shaft Held In Soft Jawed Vice
Courtesy of VOLVO CARS CORPORATION

Remove both the clamps.

Remove the boot.

Wipe off any grease.

CLEANING AND CHECKING THE OUTER JOINT

NOTE: Do not separate the outer joint.

Clean the assembled constant velocity joint and blow clean.

Check for visible damage.

Lubricate the constant velocity joint thoroughly. See **LUBRICATION TRANSMISSION** for grease quantity.

Use half the grease packaging. The remainder will be used later in the boot.

INSTALLATION

INSTALLING THE OUTER BOOT

Fig. 294: Applying Grease In Boot
Courtesy of VOLVO CARS CORPORATION

NOTE: Ensure that there is no grease on the mating surfaces between the boot and the constant velocity joint housing and the drive shaft.

CAUTION: Ensure that there are no kinks in the boots when the clamps are tightened.

Apply the remaining grease to the inside of the boot.

Remove excess grease. Use isopropanol.

Ensure that the boot is in position on the constant velocity joint housing.

Install a **new** clamp. Use: see **9512619** .

Fig. 295: Identifying Screwdriver Inserted Under Boot
Courtesy of VOLVO CARS CORPORATION

Install the inner and outer clamp. Use see **9512619** .

INSTALLING THE BOOT AND TRIPOD

Fig. 296: Identifying Installation Of Boot And Tripod
Courtesy of VOLVO CARS CORPORATION

Install:

- a **new** boot on the drive shaft with the smaller clamp
- the tripod according to the marking with the beveled splines on the tripod towards the drive shaft.

Tap in the tripod to its stop. Use: see **9995519** .

Install the snap ring, making sure it goes into its groove.

LUBRICATING WITH GREASE

Fig. 297: Identifying Application Of Grease Inside Housing And Tripod
Courtesy of VOLVO CARS CORPORATION

Lubricate the rollers on the tripod with grease.

Apply some grease to the joint housing and the rest in the boot. See **CONSTANT VELOCITY JOINT BOOT, GREASE QUANTITY** for grease quantity.

INSTALLING THE CONSTANT VELOCITY JOINT HOUSING

Fig. 298: Identifying Install Of Constant Velocity Joint Housing

Install the constant velocity joint housing. Use nylon or wooden shims.

INSTALLING AND VENTING THE BOOT

Fig. 299: Identifying Screwdriver Inserted Under Boot
Courtesy of VOLVO CARS CORPORATION

CAUTION: Ensure that there is no grease on the mating surfaces between the boot and the joint housing. Make sure that no creases form in the boot when the clamps are tightened.

Clean away excess grease with isopropanol. Slide the boot on the constant velocity joint. Ensure that the boot is in position on the constant velocity joint.

Vent the boot.

Install the cl amps.

COMPONENT SPECIFICATION

ELECTRIC FEED PUMP

COMPONENT IDENTIFICATION

Fig. 1: Identifying Electric Feed Pump
Courtesy of VOLVO CARS CORPORATION

Type

The electrical feed pump consists of a PWM controlled electrical motor and a gear pump.

Characteristic

The resistance between terminal #1 and #2 should be approximately 3 - 5 ohms at +20 °C.

TERMINAL

Fig. 2: Electric Feed Pump Connector Terminals
Courtesy of VOLVO CARS CORPORATION

Terminal connector	Control module terminal	Signal type	Miscellaneous
#1	#C2:1	Control signal, electrical feed pump.	PWM-signal, 5 V
#2	#C2:2	Ground	-

CHECK

Check 1

Measure the resistance between feed pump's terminal pin #1 and #2. The value should be approximately 3-5 ohms at +20 °C.

Check 2

Measure the resistance between the feed pump casing and terminal pin #1. The value should be much greater or infinite.

Check 3

Measure the resistance between the feed pump casing and terminal pin #2. The value should be much greater or infinite.

VEHICLE COMMUNICATION INFORMATION, DIFFERENTIAL ELECTRONIC MODULE (DEM) (B6324S, TF-80SC AWD; 2007-2008)

DESCRIPTION OF COMPONENT/FUNCTION ACTIVATION

HINT: All components/functions described do not need to be implemented in the Differential Electronic Module (DEM). This varies between different systems and markets.

COMPONENT/FUNCTION

ELECTRIC FEED PUMP

The feed pump is activated and builds up a basic pressure in the coupling.

A low humming noise can be heard from the feed pump when it is activated.

CONTROL VALVE

The control valve is controlled by means of the activation of the axial solenoid.

Following activation the solenoid changes the position of the control valve. In this way the pressure to the driven plates' working piston is regulated.

The activation can be made in two stages:

1. Min.

   Means a closed control valve which provides maximum pressure on the driven plates, which in turn provides maximum power transmission to the rear axle.

2. Max.

   Means an open control valve which provides minimum pressure on the driven plates, which in turn provides a limited power transmission to the rear axle.

DESCRIPTION OF PARAMETERS

PARAMETERS, STATUS

NOTE: The parameters that can be read off are determined by the systems with which the vehicle is equipped.

ENGINE STARTED

The value indicates whether the engine is started.

YES = Engine started.

NO = Engine not started

BRAKE PEDAL

The value indicates the status of the brake light switch. The Engine Control Module (ECM) sends a signal on the controller area network (CAN) on the position of the brake light switch: activated or not activated.

Active = Brake light switch actuated

Inactive = Brake light switch not actuated

PARKING BRAKE

The value indicates the position of the parking brake.

Active = Parking brake actuated

Inactive = Parking brake not actuated

DEM STATUS

The value specifies which status the Differential Electronic Module (DEM) detects it has (in terms of software).

OK = AOC unit (coupling) is operating normally.

Coupling fully open upon request = AOC unit (coupling) fully open (requested from Brake Control Module (BCM))

Coupling inactive or faulty (open) = AOC unit (coupling) is open due to a fault in the system.

Coupling closed = AOC unit (coupling) is closed due to a fault in the system.

ABS STATUS

The value indicates ABS modulation status. The Differential Electronic Module (DEM) obtains the value via the controller area network (CAN) from the Brake Control Module (BCM).

Active = ABS modulation

Inactive = No ABS modulation

AOC STATUS

The value specifies which status the AOC unit has (coupling). The Differential Electronic Module (DEM)

obtains the signal from the Brake Control Module (BCM). The signal is used for deactivating the AOC unit during special driving conditions.

Normal operation = Request from the Brake Control Module (BCM) for the AOC unit (coupling) to operate normally.

Rapid opening = Request from the Brake Control Module (BCM) for the AOC unit (coupling) to open quickly.

Slow opening = Request from the Brake Control Module (BCM) for the AOC unit (coupling) to open slowly.

Error in BCM = An error has occurred in the Brake Control Module (BCM) which means that the Differential Electronic Module (DEM) opens the AOC unit (coupling).

GAUGE (HIGH OIL TEMPERATURE)

The value indicates the number of times the Differential Electronic Module (DEM) has disengaged the all-wheel drive due to excessively high oil temperature.

Measurement range: 0-65534 times

PARAMETERS, VALUE

OUTSIDE TEMPERATURE

The value indicates the outside temperature.

Measurement range: -128 °C to +127.75 °C

POWER SUPPLY, DIFFERENTIAL ELECTRONIC MODULE (DEM)

The value indicates the power supply to the Differential Electronic Module (DEM).

Measurement range: 0-24 V

Normal range: 12.0-14.5 V

CEM SYSTEM VOLTAGE

The value indicates the voltage over the Central Electronic Module (CEM).

The control module transmits the signal on the controller area network (CAN) and the Differential Electronic Module (DEM) uses the signal to diagnose the power supply.

Measurement range: 5-30 V

Normal range: 12.0 - 14.5 V

OIL TEMPERATURE

The value indicates the oil temperature in the AOC coupling.

Measurement range: -128 °C to +127 °C

Normal range: 50-60 °C.

OIL PRESSURE

The value indicates the oil pressure in the AOC coupling.

Measurement range: 0-4 MPa

Normal range: 0.4-2.0 MPa.

POWER SUPPLY, SOLENOID

The value indicates the supply through the control valve's solenoid.

Measurement range: 0-4095 mA.

POWER SUPPLY, PUMP MOTOR

The value indicates the supply through the electrically driven feed pump.

Measurement range: 0-8191 mA.

TOTAL DISTANCE

The value indicates the total distance covered by the vehicle.

Measurement range: 0-16777215 km.

WHEEL SPEED

The value indicates wheel speed.

The Brake Control Module (BCM) transmits the speed signal on the controller area network (CAN) and the Differential Electronic Module (DEM) uses the signal to engage all-wheel drive.

Measurement range: 0-250 km/h.

ENGINE SPEED

The value indicates the engine's speed. The Differential Electronic Module (DEM) obtains the value via the controller area network (CAN) from the Engine Control Module (ECM).

Measurement range: 0-8191 r/min.

Idle speed: approx. 750 r/min.

CALCULATED ENGINE TORQUE

The value indicates an engine torque calculated by the Engine Control Module (ECM). The Differential Electronic Module (DEM) obtains the value via the controller area network (CAN) from the Engine Control Module (ECM).

Measurement range: -512 Nm to +511 Nm.

REAR AXLE TORQUE

The value indicates the torque transferred to the rear axle, calculated by the AOC unit (coupling).

Measurement range: 0-1020 Nm

REQUESTED ENGINE TORQUE

The value indicates the engine torque requested by the driver. The Differential Electronic Module (DEM) uses this information to correctly increase the torque transfer to the rear axle.

Measurement range: -512 Nm to +511 Nm.

DESCRIPTION OF FROZEN VALUES

EXPLANATION

Frozen values are parameter values stored when a Diagnostic Trouble Code (DTC) is generated.

All parameters are not readable for all Diagnostic Trouble Codes (DTC), but only where they can provide more information on the conditions which existed when the Diagnostic Trouble Code (DTC) was generated.

ENGINE STARTED, STATUS

The status indicates whether the engine was running when the Diagnostic Trouble Code (DTC) was generated.

No = engine was not running.

Yes = engine was running.

OUTSIDE TEMPERATURE, VALUE

The value indicates the outside temperature at the time the Diagnostic Trouble Code (DTC) was generated.

Measurement range: -128 °C to +127.75 °C.

POWER SUPPLY, DIFFERENTIAL ELECTRONIC MODULE (DEM), VALUE

The value indicates the power supply to the Differential Electronic Module (DEM) when the Diagnostic Trouble Code (DTC) was generated.

Measurement range: 0 - 24 V.

Normal range: 12.0 - 14.5 V.

TOTAL DISTANCE, VALUE

The value indicates the total distance covered by the vehicle at the time the Diagnostic Trouble Code (DTC) was generated.

Measurement range: 0 - 16777215 km.

CENTRAL ELECTRONIC MODULE (CEM) SYSTEM VOLTAGE, VALUE

The value indicates the voltage over the Central Electronic Module (CEM) when the Diagnostic Trouble Code (DTC) was generated.

Measurement range: 5 - 30 V.

Normal range: 12.0 - 14.5 V.

OIL TEMPERATURE, VALUE

The value indicates the oil temperature in the AOC coupling when the Diagnostic Trouble Code (DTC) was generated.

Measurement range: -128 °C to +127 °C.

Normal range: 50 - 60 °C.

OIL PRESSURE, VALUE

The value indicates the oil pressure in the AOC coupling when the Diagnostic Trouble Code (DTC) was generated.

Measurement range: 0 - 4 MPa.

Normal range: 0.4 - 2.0 MPa.

WHEEL SPEED, VALUE

The value indicates the wheel speed when the Diagnostic Trouble Code (DTC) was generated.

Measurement range: 0-250 km/h.

POWER SUPPLY, SOLENOID, VALUE

The value indicates the supply through the control valve's solenoid when the Diagnostic Trouble Code (DTC) was generated.

Measurement range 0 - 4095 mA.

POWER SUPPLY, PUMP MOTOR, VALUE

The value indicates the supply through the electrically driven feed pump when the Diagnostic Trouble Code (DTC) was generated.

Measurement range 0 - 8191 mA.

BRAKE PEDAL, STATUS

The status indicates brake light switch position, activated or not activated, when the Diagnostic Trouble Code (DTC) was generated.

Active = Brake light switch actuated.

Inactive = Brake light switch not actuated.

PARKING BRAKE, STATUS

The status indicates parking brake position, activated or not activated, when the Diagnostic Trouble Code (DTC) was generated.

Active = Parking brake actuated.

Inactive = Parking brake not actuated.

DEM STATUS, STATUS

The status indicates which status the Differential Electronic Module (DEM) detected it had (in terms of software) when the Diagnostic Trouble Code (DTC) was generated.

OK = AOC unit (coupling) is operating normally.

Coupling fully open upon request = AOC unit (coupling) fully open (requested from Brake Control Module (BCM)).

Coupling inactive or faulty (open) = AOC unit (coupling) is open due to a fault in the system.

Coupling closed = AOC unit (coupling) is closed due to a fault in the system.

ABS STATUS, STATUS

The status indicates whether or not the ABS brakes were modulated, when the Diagnostic Trouble Code (DTC) was generated.

Active = ABS modulation.

Inactive = No ABS modulation.

AOC STATUS, STATUS

The status indicates what the Brake Control Module (BCM) requested the AOC unit (coupling) to do when the Diagnostic Trouble Code (DTC) was generated.

Normal operation = Request from the Brake Control Module (BCM) for the AOC unit (coupling) to operate normally.

Rapid opening = Request from the Brake Control Module (BCM) for the AOC unit (coupling) to open quickly.

Slow opening = Request from the Brake Control Module (BCM) for the AOC unit (coupling) to open slowly.

Error in BCM = An error has occurred in the Brake Control Module (BCM) which means that the Differential Electronic Module (DEM) opens the AOC unit (coupling).

GAUGE (HIGH OIL TEMPERATURE), VALUE.

The value indicates the number of times the Differential Electronic Module (DEM) has disengaged the all-wheel drive due to excessively high oil temperature.

Measurement range: 0 - 65534 times.

ENGINE SPEED, VALUE

The value indicates the engine speed when the Diagnostic Trouble Code (DTC) was generated.

Measurement range:0-8191 r/min.

Idle speed: approx. 750 r/min.

CALCULATED ENGINE TORQUE, VALUE

The value indicates an engine torque calculated by the Engine Control Module (ECM) when the Diagnostic Trouble Code (DTC) was generated.

Measurement range: -512 Nm to +511 Nm.

REAR AXLE TORQUE, VALUE

The value indicates the torque transferred to the rear axle, calculated by the AOC unit (coupling) when the Diagnostic Trouble Code (DTC) was generated.

Measurement range: 0-1020 Nm

REQUESTED ENGINE TORQUE, VALUE

The value indicates the engine torque requested by the driver when the Diagnostic Trouble Code (DTC) was generated.

Measurement range: -512 Nm to +511 Nm.

VEHICLE COMMUNICATION INFORMATION, DIFFERENTIAL ELECTRONIC MODULE (DEM) (B6324S, TF-80SC AWD; 2009-2010)

DESCRIPTION OF COMPONENT/FUNCTION ACTIVATION

HINT: All components/functions described do not need to be implemented in the Differential Electronic Module (DEM). This varies between different systems and markets.

COMPONENT/FUNCTION

ELECTRIC FEED PUMP

The feed pump is activated and builds up a basic pressure in the coupling.

A low humming noise can be heard from the feed pump when it is activated.

Note that the feed pump may sound like it's running but in certain cases it only oscillates.

CONTROL VALVE

The control valve is controlled by means of the activation of the axial solenoid.

Following activation the solenoid changes the position of the control valve. In this way the pressure to the driven plates' working piston is regulated.

The activation can be made in two stages:

1. Min.

   Means a closed control valve which provides maximum pressure on the driven plates, which in turn provides maximum power transmission to the rear axle.

2. Max.

   Means an open control valve which provides minimum pressure on the driven plates, which in turn provides a limited power transmission to the rear axle.

DESCRIPTION OF PARAMETERS

PARAMETERS, STATUS

NOTE: The parameters that can be read off are determined by the systems with which the vehicle is equipped.

BRAKE PEDAL

The value indicates the status of the stop lamp switch. The engine control module (ECM) sends a signal on the controller area network (CAN) about the position of the stop lamp switch: activated or not activated.

Active = Brake light switch actuated

Not active = Stop lamp switch not affected

PARKING BRAKE

The value indicates the position of the parking brake.

Active = Parking brake actuated

Not Active = Parking brake not applied

TRAILER CONTACT CONNECTED

The value indicates if the trailer is connected to the vehicle.

The differential electronic module (DEM) obtains the value via the control area network (CAN) from the central electronic module (CEM).

The trailer module (TRM) informs the central electronic module (CEM).

Yes = Trailer connected.

No = Trailer not connected.

DEM STATUS

The value indicates the status of the differential electronic module (DEM) (software related).

OK = AOC unit (coupling) is operating normally.

Coupling fully open upon request = AOC unit (coupling) fully open (requested from Brake Control Module (BCM))

Coupling inactive or faulty (open) = AOC unit (coupling) is open due to a fault in the system.

Coupling closed = AOC unit (coupling) is closed due to a fault in the system.

Clutch overheated = Active on Demand Coupling overheated.

Clutch overheated (open) = the Active on Demand Coupling unit (clutch) is open due to overheating. No torque transferred to the rear axle.

The clutch completely locked on request = Active on Demand Coupling unit (clutch) completely locked (request from the brake control module (BCM)). Maximum torque transferred to the rear axle.

ABS STATUS

The value indicates the status of ABS control. The differential electronic module (DEM) obtains the value via the control area network (CAN) from the brake control module (BCM).

Active = ABS modulation

Inactive = No ABS modulation

AOC STATUS

The value specifies which status the AOC unit has (coupling). The Differential Electronic Module (DEM) obtains the signal from the Brake Control Module (BCM). The signal is used for deactivating the AOC unit during special driving conditions.

Normal operation = Request from the Brake Control Module (BCM) for the AOC unit (coupling) to operate normally.

Rapid opening = Request from the Brake Control Module (BCM) for the AOC unit (coupling) to open quickly.

Slow opening = Request from the Brake Control Module (BCM) for the AOC unit (coupling) to open slowly.

Error in BCM = An error has occurred in the Brake Control Module (BCM) which means that the Differential Electronic Module (DEM) opens the AOC unit (coupling).

Completely locked = Request from the brake control module (BCM) that the Active on Demand Coupling unit (clutch) should lock completely (maximum torque to the rear axle).

Torque limiting = Request from the brake control module (BCM) that the Active on Demand Coupling unit should limit the torque to the rear axle.

PARAMETERS, VALUE

POWER SUPPLY, DIFFERENTIAL ELECTRONIC MODULE (DEM)

The value indicates the power supply to the Differential Electronic Module (DEM).

Measurement range: 0 - 25.5 V

Normal range: 12.0 - 14.5 V

MECU POWER SUPPLY

The value indicates the voltage over the Central Electronic Module (CEM).

The control module transmits the signal on the controller area network (CAN) and the Differential Electronic Module (DEM) uses the signal to diagnose the power supply.

Measurement range: 0-63.75 V

Normal range: 12.0 - 14.5 V

POWER SUPPLY, PUMP MOTOR

The value indicates the supply through the electrically driven feed pump.

Measurement range 0 - 8191 mA.

POWER SUPPLY, PRESSURE REDUCING VALVE

The value shows the current through the pressure reducing valve. Measuring range: 0 - 4, 095 mA.

WHEEL SPEED

The value indicates wheel speed.

The brake control module (BCM) transmits the vehicle speed signal on the controller area network (CAN) and the differential electronic module (DEM) uses the signal to control four wheel drive.

Measurement range: 0 - 255 km/h.

ENGINE SPEED (RPM)

The value indicates the engine's speed. The Differential Electronic Module (DEM) obtains the value via the controller area network (CAN) from the Engine Control Module (ECM).

Idle speed: approx. 750 r/min.

Measurement range: 0-8191 r/min.

ECU-TEMPERATURE

The value shows the temperature in Differential electronic module (DEM). The temperature sensor is located on the circuit board.

Measurement range: -60 to +195 °C.

CALCULATED FRONT WHEEL DRIVE TORQUE

The value indicates one engine control module (ECM) calculated torque, supplied to the Active on Demand Coupling input shaft (propeller shaft). Calculation includes the gear ratio of the transmission and the final drive. The differential electronic module (DEM) obtains the value via the controller area network (CAN) from the engine control module (ECM).

Measurement range: -16.376 Nm to +16.384 Nm.

REAR AXLE TORQUE

The value indicates the torque transferred to the rear axle, calculated by the AOC unit (coupling).

Measurement range: 0 - 8191 Nm.

REQUESTED REAR AXLE TORQUE

The value indicates one brake control module (BCM) requested maximum rear axle torque. The differential electronic module (DEM) uses this information to correctly transfer torque to the rear axle.

Measurement range: 0 - 8191 Nm.

REQUESTED FRONT WHEEL DRIVE TORQUE

The value indicates the requested engine torque of the driver. The differential electronic module (DEM) uses this information to correctly transfer torque to the rear axle.

Measurement range: -16.376 Nm to +16.375 Nm.

DESCRIPTION OF FROZEN VALUES

EXPLANATION

Frozen values are parameter values stored when a Diagnostic Trouble Code (DTC) is generated.

TOTAL MILEAGE, VALUE

The value indicates the total distance covered by the vehicle at the time the Diagnostic Trouble Code (DTC) was generated.

Measurement range: 0 -16,777,215 km.

MECU POWER SUPPLY, VALUE

The value indicates the voltage over the Central Electronic Module (CEM) when the Diagnostic Trouble Code (DTC) was generated.

Measurement range: 0 -64 V.

Normal range: 12.0 - 14.5 V.

OUTSIDE TEMPERATURE, VALUE

The value indicates the outside temperature at the time the Diagnostic Trouble Code (DTC) was generated.

Measurement range: -40 °C to +215 °C.

ENGINE STATUS

Indicates if the engine is running.

No = Engine off

Yes = Engine running

ENGINE START IN PROGRESS

Indicates if start attempt is in progress.

No = Engine not cranking

Yes = Engine cranking

ECU-TEMPERATURE

The value shows the temperature in Differential electronic module (DEM). The temperature sensor is located on the circuit board.

POWER SUPPLY, DIFFERENTIAL ELECTRONIC MODULE (DEM), VALUE

The value indicates the power supply to the Differential Electronic Module (DEM) when the Diagnostic

Trouble Code (DTC) was generated.

Measurement range: 0 -25.5 V.

Normal range: 12.0 - 14.5 V.

WHEEL SPEED, VALUE

The value indicates the wheel speed when the Diagnostic Trouble Code (DTC) was generated.

Measurement range: 0 - 255 km/h.

POWER SUPPLY, PRESSURE REDUCING VALVE

The value displays the current through the pressure reducing valve.

Measurement range 0 - 4095 mA.

POWER SUPPLY, PUMP MOTOR

The value indicates the supply through the electrically driven feed pump when the Diagnostic Trouble Code (DTC) was generated.

Measurement range 0 - 8191 mA.

DEM STATUS

Indicates the status of the differential electronic module (DEM) (software related) when the diagnostic trouble code was stored.

OK = AOC unit (coupling) is operating normally.

Coupling fully open upon request = AOC unit (coupling) fully open (requested from Brake Control Module (BCM))

Coupling inactive or faulty (open) = AOC unit (coupling) is open due to a fault in the system.

Coupling closed = AOC unit (coupling) is closed due to a fault in the system.

AOC STATUS

Indicates the status of the Active on Demand Coupling when the diagnostic trouble code (DTC) was stored. The differential electronic module (DEM) obtains the signal from the brake control module (BCM). The signal is used to deactivate the Active on Demand Coupling during special driving conditions.

Normal operation = Request from the Brake Control Module (BCM) for the AOC unit (coupling) to operate normally.

Rapid opening = Request from the Brake Control Module (BCM) for the AOC unit (coupling) to open quickly.

Slow opening = Request from the Brake Control Module (BCM) for the AOC unit (coupling) to open slowly.

Error in BCM = An error has occurred in the Brake Control Module (BCM) which means that the Differential Electronic Module (DEM) opens the AOC unit (coupling).

Completely locked = Request from the brake control module (BCM) that the Active on Demand Coupling unit (clutch) should lock completely (maximum torque to the rear axle).

Torque limiting = Request from the brake control module (BCM) that the Active on Demand Coupling unit should limit the torque to the rear axle.

DIAGNOSTIC INFORMATION, STATUS

Indicates the diagnostic status of the differential electronic module (DEM) when the diagnostic trouble code (DTC) was stored.

No diagnostic trouble code (DTC) = No diagnostic trouble code (DTC) is stored in the control module.

At least one diagnostic trouble code (DTC) = At least one diagnostic trouble code (DTC) is stored in the control module.

All diagnostic tests have not been carried out = All diagnostic tests in the control module have not been carried out.

All diagnostic tests have been carried out = All diagnostic tests in the control module have been carried out

BRAKE PEDAL, STATUS

Indicates the stop lamp switch position, activated or not activated, when the diagnostic trouble code (DTC) was stored.

Active = Brake light switch actuated.

Not active = Stop lamp switch off.

PARKING BRAKE, STATUS

Indicates the parking brake position, activated or not activated, when the diagnostic trouble code (DTC) was stored.

Active = Parking brake actuated.

Not active = Parking brake not applied.

ABS STATUS

Indicates the status of ABS control when the diagnostic trouble code (DTC) was stored. The differential electronic module (DEM) obtains the value via the control area network (CAN) from the brake control module (BCM).

Active = ABS modulation.

Inactive = No ABS modulation.

GAUGE (HIGH OIL TEMPERATURE), VALUE.

The value indicates the number of times the Differential Electronic Module (DEM) has disengaged the all-wheel drive due to excessively high oil temperature.

Measurement range: 0-65,534 times.

ENGINE SPEED, VALUE

The value indicates the engine speed when the Diagnostic Trouble Code (DTC) was generated.

Measurement range:0-8191 r/min.

Idle speed: approx. 750 r/min.

ENGINE TORQUE

The value indicates an engine control module (ECM)-calculated torque, supplied to the Active on Demand Coupling input shaft (propeller shaft) when the diagnostic trouble code (DTC) was stored. Calculation includes the gear ratio of the transmission and the final drive. The differential electronic module (DEM) obtains the value via the controller area network (CAN) from the engine control module (ECM).

Measurement range: -16.376 Nm to +16.384 Nm.

REAR AXLE TORQUE, VALUE

The value indicates the torque transferred to the rear axle, calculated by the AOC unit (coupling) when the Diagnostic Trouble Code (DTC) was generated.

Measurement range: 0 -8191 Nm

REQUESTED ENGINE TORQUE

The value indicates the requested engine torque of the driver when the diagnostic trouble code (DTC) was stored. The differential electronic module (DEM) uses this information to correctly transfer torque to the rear axle.

Measurement range: -16.376 Nm to +16.375 Nm.

ENGINE RUNNING

The value indicates if the engine has started.

YES = The engine has started.

NO = Engine not started

PARAMETERS, VALUE

OUTSIDE TEMPERATURE

The value indicates the outside temperature.

Measurement range: -128 °C to +127.75 °C

PASSENGER COMPARTMENT TEMPERATURE

The value indicates the passenger compartment temperature in the car.

Measurement range: -60 °C to +195 °C.

CONTROL MODULE POWER SUPPLY

The value indicates the power supply to the differential electronic module (DEM).

Measurement range: 0 - 24 V

Normal range: 12.0 - 14.5 V

CEM SYSTEM VOLTAGE

The value indicates the voltage at the central electronic module (CEM).

The control module transmits the signal on the controller area network (CAN) and the differential electronic module (DEM) uses the signal to diagnose the power supply.

Measurement range: 5 - 30 V

Normal range: 12.0 - 14.5 V

OIL TEMPERATURE

The value indicates the oil temperature in the Active on Demand Coupling.

Measurement range: -128 °C to +127 °C

Normal range: 50 - 60 °C.

OIL PRESSURE

The value indicates the oil pressure in the Active on Demand Coupling.

Measurement range: 0 - 4 MPa

Normal range: 0.4 -2.0 Mpa.

POWER SUPPLY SOLENOID

The value indicates the current through the control solenoid for four wheel drive.

Measurement range: 0 - 4095 mA.

POWER SUPPLY PUMP MOTOR

The value displays the current through the hydraulic feed pump.

Measurement range: 0 - 8191 mA.

TOTAL MILEAGE

The value indicates the total covered mileage of the vehicle.

Measurement range: 0 - 1048575 km.

WHEEL SPEED

The value indicates the wheel speed.

The brake control module (BCM) transmits the vehicle speed signal on the controller area network (CAN) and the differential electronic module (DEM) uses the signal to activate four wheel drive.

Measurement range: 0-250 km/h.

  Check the connector for the control module for four wheel drive (Active on Demand Coupling). Check

for damaged or bent terminal pins. Check for contact resistance and oxidation.

Check the wiring for CAN communication between terminal #7 on the control module for four wheel drive (Active on Demand Coupling) and brake control module (BCM) terminal #11 (#A11) and between terminal #8 on the control module for four wheel drive (Active on Demand Coupling) and brake control module (BCM) terminal #15 (#A15). Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.

Also check if the wiring for CAN communication is too close to a source of interference such as a carphone etc.

Remedy as necessary.

- Ignition off.

  Check the following seals and sealing joints:

  - the seal for the input shaft
  - the seal joint between the coupling (Active on Demand Coupling) and the rear axle
  - the seal joint between the control module and the housing.

  If there is oil leakage from the bleed hole:

  Remove the level plug and top up with oil, P/N 116 1329. Fill until oil escapes from the level plug hole.

Then drain 0.25 l of oil. Install the level plug.

Remedy any leakage.

CHECKING FOUR WHEEL DRIVE (4T65 AWD; AW50/51 AWD; 2003-2004)

CHECKING FOUR WHEEL DRIVE

FUNCTION CHECK

WARNING: Ensure that the car is safely raised. Check that no objects are caught in the tire treads.

CAUTION: Carry out the test with the car raised so that all four wheels can rotate freely with the mounting at the ends of the control arms to prevent damage to the drive shafts.

NOTE: If the car has STC or DSTC, these functions must be disengaged. Press in the STC/DSTC button on the center console. Hold the button in for at least 2 seconds. The LED on the button must go out.

If the car is equipped with TRACS (traction control system) the function must be deactivated. This is carried out by removing the fuse for the ABS modulator in the engine compartment fusebox. Note that diagnostic trouble codes (DTCs) will be stored in the brake control module (BCM). These must be erased before returning the car to the customer.

- Ignition off
- Raise the car so that all the driven wheels are clear of the ground
- Depress the brake pedal
- Move the gear selector to position P
- Start the engine and release the parking brake
- Move the gear selector to position D
- Release the brake pedal when the car is idling. If at least one wheel on each axle rotates, the Active on Demand Coupling is verified as being active and the feed pump for the Active on Demand Coupling functioning. Note any faulty function. If the front wheels rotate at normal speed and the rear wheels do not rotate this means that the Active on Demand Coupling function is faulty. Note any faulty function
- Depress the accelerator pedal (AP) and maintain a speed of approximately 60-80 km/h. Check that all wheels rotate at the same speed
- Release the accelerator pedal (AP)
- Select N immediately after releasing the accelerator pedal (AP)
- Apply the parking brake when the wheels are still rotating at 60-80 km/h. Check that the rear wheels stop abruptly and that the front wheels continue to rotate. If this is the case the quick release in the control valve functions. Note any faulty function. If all wheels stop immediately when the parking brake is applied, operation of the valve is not functioning. This may be caused by a function fault in the Active on Demand Coupling. Note any faulty function
- Release the parking brake and depress the brake pedal. All wheels must stop
- Move the gear selector to position D
- Release the brake pedal.

CAUTION: Carry out the test with the car raised so that all four wheels can rotate freely with the mounting at the ends of the control arms to prevent damage to the drive shafts.

NOTE: STC (stability and traction control)/DSTC (dynamic stability and traction control) function is deactivated.

- Ignition off
- Raise the car so that all the driven wheels are clear of the ground
- Depress the brake pedal
- Move the gear selector to position P
- Start the engine with the parking brake applied. The indicator lamp in the combined instrument panel must light
- Move the gear selector to position D
- Release the brake pedal when the car is idling. If the front wheels rotate slowly and the rear wheels do not rotate the Active on Demand Coupling is OK. Replace the differential electronic module (DEM) if the front wheels rotate at normal speed, the rear wheels do not rotate, the oil level is correct and the previous test was carried out without faults.

- Ignition off
- Raise the car so that all the driven wheels are clear of the ground
- Move the gear selector to the N position
- Start the engine with the parking brake applied
- Let the engine idle. Attempt to rotate both the front wheels at the same time.

NOTE: The basic function of the Active on Demand Coupling and the function of the oil pump for the Active on Demand Coupling can be verified by checking to, see if the brake force on the rear wheels also brakes the front wheels.

- Disconnect the 2-pin connector between the differential electronic module (DEM) and the feed pump
- When the basic pressure drops, the successive reduction in basic pressure can be felt by the reduction and ceasing of the basic torque
- Connect the connector between the differential electronic module (DEM) and the feed pump
- The build up of basic pressure in the clutch can be felt when the front wheels brake via the Active on Demand Coupling
- Disconnect the 8-pin connector between the differential electronic module (DEM) and the cable from the car.

NOTE: When the power supply to the differential electronic module (DEM) is cut, the choke valve quickly opens. This is verified by the basic torque ceasing immediately.

- Connect the connector for the differential electronic module (DEM)
- Note that the feed pump for the Active on Demand Coupling starts. On Startup an increase in speed of the pump can be heard
- Switch off the engine and leave the ignition on
- Leave the parking brake applied and the gear selector in position N
- The feed pump for the Active on Demand Coupling must not rotate in this position.

If the basic function of the Active on Demand Coupling and the function of the feed pump for the Active on Demand Coupling are verified and the test is OK, replace the Active on Demand Coupling.

TEST DRIVING

Fig. 9: Identifying Test Drive
Courtesy of VOLVO CARS CORPORATION

WARNING: **Observe all traffic regulations during the test drive.**

HINT: The test drive consists of two tests. The first test is at low engine speeds (RPM). The second is at higher engine speeds (RPM).

HINT: At low engine speeds (RPM), four wheel drive is normally disengaged. At high engine speeds, four wheel drive will be engaged. This will have a braking effect when the clutch is depressed and the accelerator pedal (AP) is released.

HINT: The stopping distance with four wheel drive engaged must be approximately half the distance of that when four wheel drive is disengaged.

The test drive

Drive the car in a circle at full lock (the smallest turning circle) at a speed of approximately 10 km/h. Press the clutch and release the accelerator pedal (AP). Let the car come to a standstill.

Note how long it took for the car to stop.

Repeat the test. Increase the engine speed to 3000-4000 rpm. Let the car come to a standstill.

The car will stop in half the distance it took to stop in the first test if the function is correct.

Drive the car while looking out for any faults in functions or noise from the rear suspension.

If there is a fault or noise, stop the test drive. Return to the workshops. Fault trace the symptoms.

CHECKING INCORRECT ENGAGEMENT OF FOUR-WHEEL DRIVE (4T65 AWD; 2006)

CHECKING INCORRECT ENGAGEMENT OF FOUR-WHEEL DRIVE

FAULT-TRACING INFORMATION

Differential electronic module (DEM) checks engagement and disengagement of four-wheel drive. The control module controls engagement and disengagement using a number of parameters, among others, by comparing speed of the wheels. If the vehicle's tires are worn unevenly (compared front and rear, or if a tire with incorrect dimension is installed (compared with the vehicle's other tires) on the vehicle's front or rear axle, this may result in incorrect engagement of four-wheel drive. Incorrect engagement of four-wheel drive may be experienced as jerk or hack when driving.

Incorrect engagement is if four-wheel drive is activated at a time when the following parameters are fulfilled:

- Constant vehicle speed (above 20 km/h).
- Constant engine rpm.
- Brake pedal released (no braking).
- The parking brake is not applied.
- Engine brake not active (accelerator pedal pressed down).

Causes of interference can be:

- Unevenly worn tires (compared front and rear).
- Tire with incorrect dimension has been installed on front or rear axle (compare with other tires on the vehicle).

- **Continue**

  Refer to **CHECKING TIRE WEAR**

CHECKING TIRE WEAR

Check tires for wear. The tires shall be worn evenly when comparing front and rear. Check that all tires have the same dimension. If any or some tires are more worn than the others or have a different dimension, it is recommended that these are replaced.

- **Continue**

Refer to **CHECKING SOFTWARE VERSION**

CHECKING SOFTWARE VERSION

From and incl. week 39 year 2007, there is software with greater tolerance for different wheel speeds, this to minimize the risk of incorrect engagement of four-wheel drive at, e. g., slightly unevenly worn tires. The rolling circumference may vary slightly even on new tires.

Check if new software is available for download in Differential electronic module (DEM).

- **Continue**

  Refer to **TEST DRIVING AND READING OFF DIAGNOSTIC TROUBLE CODES (DTCS)**

TEST DRIVING AND READING OFF DIAGNOSTIC TROUBLE CODES (DTCS)

After changing tire and/or new software has been downloaded in the control module, the vehicle shall be test-driven and then read out with VIDA (Volvo scan tool). Before test-driving, connect VIDA and read out parameter "Number of detections of malfunction condition" via CAR COMMUNICATION/Parameters. Note the quantity.

Test-drive the vehicle and fulfill the following criteria at the same time at least once:

- Constant vehicle speed (above 20 km/h).
- Constant engine rpm.
- Brake pedal released (no braking).
- Engine brake not active (accelerator pedal pressed down).

After test-driving:

Connect VIDA and read out parameter "Number of detections of malfunction condition" via CARCOMMUNICATION/Parameters. Compare the number before and after test-driving, if the number of "detections of malfunction condition" is higher after test-driving it indicates that Differential electronic module (DEM) has detected "incorrect engagement" of four-wheel drive.

The parameter "Number of detections of malfunction condition" is only counted up once per driving cycle if "incorrect engagement" is detected.

Has the counter counted up after test-driving?

- **YES**

  Refer to **INFORMATION**

- **NO**

CHECKING INTERMITTENT FOUR-WHEEL DRIVE (B6324S, TF-80SC AWD; 2009-2010)

CHECKING INTERMITTENT FOUR-WHEEL DRIVE

CHECKING INTERMITTENT FOUR-WHEEL DRIVE

NOTE: Before troubleshooting of four-wheel drive is performed, the components included in the power transmission shall be checked with regards to mechanical damages.

A working pressure is needed to enable torque transmission to the rear axle. This pressure is built up by the feed pump. The feed pump works in intervals to build up a max. pressure. Then the working pressure is adjusted via a pressure control valve. When the feed pump is not active, the pressure is maintained in the system via an accumulator.

If the clutch has an internal leak or a damaged accumulator then the system will, when the pump is not active, lose the pressure that is needed for the torque to be transmitted. Then the four-wheel drive works intermittently, that is, it works when the feed pump works and does not work when the pump is turned off.

This may be difficult to detect by test-driving. To obtain a meaningful test of this, the following test-driving case can be performed at the same time as "power supply pump motor" is read out in the parameter list under vehicle communication. This is to check that four-wheel drive is available even when the feed pump is not active.

- Test-driving on rollers.
- Start and driving uphill on "slippery" ground.

NOTE: **This failure is not solved by replacing Differential electronic module (DEM), it is solved by replacing clutch four-wheel drive.**

- Ignition off.

  Checking the oil level

  Check the oil level in the coupling (Active on Demand Coupling).

  If the oil level is low, check for leaks at:

  - the seal for the input shaft
  - the seal joint between the coupling (Active on Demand Coupling) and the rear axle
  - the seal joint between the control module and the housing.

Check the quality of the oil

Also check the quality of the oil by feeling and smelling it.

If the oil is dark and smells burnt, the AOC (Active on Demand Coupling)unit must be replaced.

If there are shavings or particles in the oil, the AOC (Active on Demand Coupling)unit must be replaced.

Other information

- To remove the coupling (Active on Demand Coupling):

Only oil P/N 116 1641 (0.3 liter containers) may be used.

Tighten the level plug. Tighten to **35 Nm** .

Volume approximately 0.8 liters.

CAUTION: If the AOC (Active on Demand Coupling) has been replaced with a new one, the car must be driven carefully in tight circles in both directions and then driven for a few kilometers after the oil is filled. Recheck and top up the oil level as above.

INSTALLING THE PROPELLER SHAFT

Install the propeller shaft. See **REAR AXLE, DRIVE SHAFTS - REMOVAL, REPLACEMENT AND INSTALLATION** .

INSTALLING THE EXHAUST SYSTEM

Install the exhaust system. See **INTAKE AND EXHAUST SYSTEM - REMOVAL, REPLACEMENT AND INSTALLATION** .

No diagnostic trouble codes (DTCs) stored in the control module for four wheel drive (Active on Demand Coupling).

Fault symptom[s]

- No four wheel drive.

CHECKING PRESSURE CONTROL VALVE (B6324S, TF-80SC AWD; 2009-

2010)

CHECKING PRESSURE CONTROL VALVE

CHECKING PRESSURE CONTROL VALVE

The pressure control valve is located in Differential electronic module (DEM). It controls the pressure to the clutch.

If symptom like the vehicle's wheels lose traction and/or the vehicle skipping ahead when cornering, the problem may be the pressure control valve. In case of valve failure, the power transmission cannot be controlled in a correct way. This may mean that the difference, needed when the vehicle turns, between the inner and the outer wheels is lost. Test-drive the vehicle in an eight to, see if there are symptoms like; noise in rear axle, that the vehicle skips or that any of the wheels lose traction.

In case of failed pressure control valve, Differential electronic module (DEM) must be replaced.

CHECKING THE FOUR WHEEL DRIVE (B6324S, TF-80SC AWD; 2007-2008)

CHECKING THE FOUR WHEEL DRIVE

FUNCTION TEST

CAUTION: The test must be carried out on a raised vehicle so that all four wheels are free to turn, with attachment a long way out on the link arms, so as not to damage the drive shafts.

WARNING: Ensure that the vehicle is safely raised. Check that no objects are caught in the tire treads.

NOTE: If the vehicle has STC or DSTC, the function must be de-activated. Depress the STC/DSTC button on the centre console and hold it down for more than 2 seconds. The LED on the button should switch off.

If the vehicle has TRACS, this function must also be deactivated. This is done by removing the fuse for the ABS unit from the engine compartment electrical centre. Note that this will cause trouble codes to be set in the Brake Control Module (BCM). These codes must be erased before the vehicle is returned to the customer.

- Ignition off
- Raise the vehicle so that all the driving wheels are hanging free.
- Push down the brake pedal.
- Move the gear selector lever to the P position.
- Start the engine and release the handbrake.
- Move the gear selector lever to the D position.
- Release the brake pedal while the engine is idling. If at least one wheel on each axle rotates, verify that

both the AOC clutch and its feed pump are active. Make a note of any malfunction. If the front wheels rotate at normal speed but the rear wheels do not rotate this means that the AOC clutch is not functioning correctly. Make a note of any malfunction.

- Push down the accelerator pedal and hold a speed of about 60-80 km/h. Check that all the wheels rotate at the same speed.
- Release the accelerator pedal.
- Position the gear selector lever in the N position immediately after releasing the accelerator pedal.
- Pull on the handbrake while the wheels are still rotating and a speed of 60-80 km/h is indicated. Check that the rear wheels stop immediately and that the front wheels continue to rotate. If this is so, then the rapid opening function of the control valve is operating correctly. Make a note of any malfunction. If all the wheels stop rapidly when the handbrake is applied then the valve control is not working correctly. This may be due to a fault in the AOC clutch. Make a note of any malfunction.
- Release the handbrake and depress the brake pedal. All the wheels should stop.
- Position the gear selector lever in the D position.
- Release the brake pedal.

- **Continue**

  Refer to **FUNCTION TEST**

WARNING: Ensure that the vehicle is safely raised. Check that no objects are caught in the tire treads.

NOTE: The STC/DSTC function is deactivated.

- Ignition off
- Raise the vehicle so that all the driving wheels are hanging free.
- Push down the brake pedal.
- Move the gear selector lever to the P position.
- Start the engine with the handbrake applied. The control lamp in the combination instrument panel should illuminate.
- Move the gear selector lever to the D position.
- Release the brake pedal while the engine is idling. If the front wheels rotate slowly and the rear wheels are stationary the AOC clutch is OK. If the front wheels rotate at normal speed while the back wheels are stationary then, if the oil level is correct and no fault was found in the previous test, the Differential Electronic Module (DEM) must be replaced.

Other information:

- see **DIFFERENTIAL ELECTRONIC MODULE (DEM), REPLACING**

  OKAY: Troubleshooting has been completed.

FUNCTION TEST

CAUTION: The test must be carried out on a raised vehicle so that all four wheels are free to turn, with attachment a long way out on the link arms, so as not to damage the drive shafts.

WARNING: Ensure that the vehicle is safely raised. Check that no objects are caught in the tire treads.

NOTE: The STC/DSTC function is deactivated.

- Ignition off
- Raise the vehicle so that all the driving wheels are hanging free.
- Move the gear selector lever to the N position.
- Start the engine with the handbrake applied.
- Let the engine idle while attempting to rotate by hand both the front wheels.

NOTE: The base function of the AOC clutch and the function of its feed pump are verified by checking whether the braking effect on the rear wheels also brakes the front wheels.

- Unplug the 2-pin connector between the Differential Electronic Module (DEM) and the feed pump.
- The gradual sinking of the base pressure is apparent as the base torque diminishes and eventually ceases.
- Plug in the connector between the Differential Electronic Module (DEM) and the feed pump.
- The increase in the base pressure in the clutch is made apparent by the braking of the front wheels via the AOC clutch.
- Unplug the 8 pin connector between the Differential Electronic Module (DEM) and the cable from the

vehicle.

NOTE: When the power supply to the Differential Electronic Module (DEM) is removed the regulator valve will open rapidly. This is verified by the immediate cessation of the base torque.

- Plug in the connector to the Differential Electronic Module (DEM)
- Note that the feed pump to the AOC clutch starts. It can be heard that the pump runs at a higher speed when starting.
- Switch of the engine and leave the ignition on.
- Leave the handbrake on and the gear selector lever in the N position.
- The AOC clutch feed pump should not rotate under these conditions.

When the base pressure function of the AOC clutch and the function of the feed pump have been verified and the tests are OK, replace the AOC clutch.

When the base pressure function of the AOC clutch and the function of the feed pump have been verified and the tests are **not** OK, replace the Differential Electronic Module (DEM).

- Ignition off
- Disconnect the connector for the pump motor
- Start the engine.

  Check the voltage for the pump motor by taking readings between terminals #1 and #2 on the pump motor connector (control module side). The voltage must be within specification.

  If the voltage is not OK, check the wiring between the control module for four wheel drive (Active on Demand Coupling) and the pump motor. Check for an open-circuit. Check for a short-circuit to each other.

  Replace the oil pump motor if the voltage is OK.

Remedy as necessary.

CHECKING WATER IN OIL

CHECKING WATER IN OIL

If symptoms such as disc screech or noise from the clutch appear, this may be due to water in the oil. Check if the oil contains water.

If the oil contains water, the Goretex filter located on the clutch may have worked loose.

- Check if the Goretex filter has worked loose.
- Check if the oil filter is sticky and dirty.

If the oil contains water, change the oil. If the oil filter is sticky, change oil and filter. If the Goretex filter is gone, it must be replaced.

If the problem remains, replace the clutch.

INSTALLING THE CONTROL ARM ON THE BALL JOINT

Install the drive shaft in the hub. Align the ball joint against the control arm.

Release the tensioning strap between the control arms.

Install a nut on the ball joint. (M10)

NOTE: Counterhold using the Torx wrench so as not to damage the boot.

Remove the tensioner strap.

INSTALLING THE CABLE HARNESS FOR THE ABS SENSOR

Install the cable harness in the brackets.

INSTALLING THE ANTI-ROLL BAR LINK

Install:

- the anti-roll bar link
- the nut (M12).

NOTE: Counterhold using a Torx wrench so that the boot for the link is not damaged.

INSTALLING THE STEERING ARM

Install:

- the steering arm
- the nut.

For tightening torques, see **TIGHTENING TORQUE** .

NOTE: Counterhold using the wrench grip so that the screw does not rotates and damage the rubber boot.

INSTALLING THE BRAKE DISC

Install:

- the brake disc
- the screw.

INSTALLING THE DRIVE SHAFT SCREW

Install a new screw. Use a screwdriver as a counterhold.

Lubricate the wheel bearing sealing lip abutting the drive shaft with a little wheel bearing grease. P/N 1161689.

Brush high pressure grease, P/N 1161246 onto the drive shaft so that the splines on the rear half of the drive shaft pin are filled.

INSTALLATION

NOTE: For tightening torque, see TIGHTENING TORQUE and TIGHTENING TORQUE .

INSTALLATION OF HUB AND DRIVE SHAFT

Install:

- the hub on the stub axle and drive shaft.

  Use new screws. Tighten. See: **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS**

- a new screw loosely on the drive shaft. The screw will be tightened later
- the wheel sensor M6, tighten according to: **TIGHTENING TORQUE** .

REMOVING THE TENSIONER

Ensure that the brake disc and wheel rim mating surfaces are clean. Grease the hub center location dowel for the rim. Use installation paste **1161397-3** .

Install the wheel studs lightly. Then tighten crosswise. Tighten to **140 Nm** . Use torque socket see **9512835** if an impact wrench is being used.

Crosswise tightening and torque tightening is important to prevent stresses in the brake disc.

NOTE: **The torque socket is designed for use with a standard, pneumatic impact nut runner providing a torque of 250-350 Nm .**

- Slacken off the lower screws for the compressor (so that there is some clearance)
- Disconnect the battery positive lead
- Disconnect the connector
- Remove the generator (GEN)
- Turn the generator (GEN) into position
- Pull the generator (GEN) upwards/away.

INSTALLATION

NOTE: For tightening torques, see TIGHTENING TORQUE .

INSTALLING GENERATOR (GEN)

- Position the generator (GEN). Install the screw through the upper mounting. Do not tighten
- Connect the cable and the connector
- Install the lower screws for the generator and upper screws for the compressor
- **With AC:** Tighten the 2 lower screws for the compressor. M8
- Tighten the 3 screws for the generator (GEN). M8.

FINISHING WORK

Install:

- the turbocharger hose
- the power steering pump. See **POWER STEERING PUMP, REPLACING**

Remove the pulley.

INSTALLATION

NOTE: For tightening torques, see TIGHTENING TORQUE .

INSTALLING A PULLEY WITHOUT FREEWHEEL

Install the pulley and the nut. Use ring wrench see **9512036** and twelve point socket see **9512849** .

Tighten.

Install the auxiliaries belt. See **AUXILIARIES BELT/BELT TENSIONER, REPLACING** .

Test the function.

INSTALLING THE PULLEY WITH FREEWHEEL

Thread the pulley on to the rotor shaft.

Tighten. Use tools see **9995760** and see **9512849** as shown.

Install the dust cover.

Install the auxiliaries belt. See **AUXILIARIES BELT/BELT TENSIONER, REPLACING** .

- the generator (GEN).

Lift out the generator.

INSTALLATION

NOTE: For tightening torques, see TIGHTENING TORQUE

INSTALLING GENERATOR (GEN)

Lift the generator into place.

Install:

- the 3x M8 screws
- the connector
- the battery positive lead. Tighten. See **SUMMARY OF TIGHTENING TORQUES FOR SPECIFIC COMPONENTS** .

NOTE: **If the vehicle is equipped with air conditioning (A/C), tighten the lower 2 x M8 screws for the compressor.**

FINISHING

INSTALLING COMPONENTS

Install:

- the radiator hose
- the turbo hose
- the power steering pump. See **POWER STEERING PUMP, REPLACING**
- the auxiliaries belt. See **REPLACING THE ACCESSORY DRIVE BELT/BELT TENSIONER**
- the battery negative lead. See **BATTERY, DISCONNECTING**

Check the fluids level. Top up if required.

REPLACING THE PULLEY WITH FREEWHEEL/FIXED PULLEY

NOTE: **As the graphics in this service information are used for different model years and/or models, some variation may occur. However, the essential information in the graphics is always correct.**

REMOVING A PULLEY WITH FREEWHEEL

Fig. 20: Identifying Tool 9995760 And Twelve Toothed Dowel
Courtesy of VOLVO CARS CORPORATION

Removing a pulley with freewheel

- remove the dust cover
- use tool **9995760** as shown
- use a twelve toothed dowel, see **1159080** , as shown

NOTE: When removing: The rotor shaft and pulley are left-hand threaded.

- disconnect the pulley from the rotor shaft
- remove the pulley.

INSTALLING THE PULLEY WITH FREEWHEEL

Fig. 21: Identifying Tool 9995760 And Twelve Toothed Dowel
Courtesy of VOLVO CARS CORPORATION

Installing a pulley with freewheel

- slide the pulley onto the rotor shaft
- use tool **9995760** on the pulley, as shown
- use a twelve toothed dowel, see **1159080** as shown

NOTE: The rotor shaft and pulley are left-hand threaded.

- tighten the pulley. Tighten to 80 Nm (59 lbs.)
- install the dust cover.

Checking the function of the freewheel on the generator (GEN) in the car

Check the pulley freewheel as follows:

- start the engine
- rev the engine to 3, 000 rpm.

  Ensure that no extra power consuming components are connected.

Check that only a weak clicking sound is heard when the freewheel engages and disengages

- switch off the engine. Check that the generator rotates for longer than the engine.

If it is cold, the battery charge warning lamp may light shortly after start-up because the freewheel needs to rotate and warm up the bearing grease before it locks and engages the rotor shaft.

If the warning lamp remains lit, it may be an indication that the freewheel has not locked the pulley to the rotor shaft.

Check

Checking the function of the freewheel on a removed generator (GEN)

Check the pulley freewheel as follows

- rotate the pulley counter-clockwise and brake heavily.

  The freewheel should grip the rotor shaft when rotating counter-clockwise

- stop the rotation.

  When braking the pulley, the freewheel mechanism should release so that the rotor shaft continues to rotate.

This method allows the function of the freewheel to be checked easily.

REMOVING A FIXED PULLEY

Fig. 22: BIHEXAGON BIT ADAPTOR M10
Courtesy of VOLVO CARS CORPORATION

Removing a fixed pulley

- use a wrench, see **9512036** to hold the nut as shown
- use a twelve toothed dowel, see **1159079** , on the rotor shaft
- remove the nut and remove the pulley.

INSTALLING A FIXED PULLEY

Fig. 23: Identifying Wrench And Toothed Dowel
Courtesy of VOLVO CARS CORPORATION

Installing a fixed pulley

- thread the pulley onto the rotor shaft
- thread the nut
- use a wrench, see **9512036** and a twelve toothed dowel, see **1159079** as shown
- tighten the pulley. Tighten to 65 Nm (48 ft. lb).

- **With AC:** Slacken off the lower screws for the compressor (so that there is some clearance)
- Disconnect the battery positive lead
- Disconnect the connector
- Remove the generator (GEN)
- Turn the generator (GEN) into position
- Carefully pry the front panel forwards
- Pull the generator (GEN) upwards/away.

INSTALLATION

NOTE: For tightening torques, see TIGHTENING TORQUE .

INSTALLING GENERATOR (GEN)

- Position the generator (GEN). Install the screw through the upper mounting. Do not tighten
- Connect the cable and the connector
- Install the lower screws for the generator (upper screws for the compressor).

- **With AC:** Tighten the 2 lower screws for the compressor. M8

- Tighten the 3 screws for the generator (GEN). M8.

FINISHING WORK

Install:

- the front panel
- the bumper cover
- the right-hand headlamp. See **HEADLIGHT/BULB, REPLACING**

STANDBY CURRENT, MEASURING/FAULT-TRACING (2003-04)

PREPARATIONS FOR MEASURING THE STANDBY POWER CONSUMPTION

Factors such as whether the alarm is on or off or whether any doors are open affect the rate at which the car will reach standby power consumption. The lowest power consumption is reached most quickly if the alarm is on (approximately 12 minutes after activation).

When the car doors are closed, it takes approximately 12 minutes after the last door was shut and the ignition switched off. If any of the doors are open, it takes approximately 20 minutes.

For time considerations, it is recommended that the alarm is switched on. This is the case described below.

Preparations for measuring the standby power consumption

Fig. 1: Using Screwdriver To Lock Driver's Side Door Lock
Courtesy of VOLVO CARS CORPORATION

- Check that all the lighting is switched off
- Open the boot lid or tailgate. Use a screwdriver to set the lock to the lock position
- Close and lock the doors. Activate the alarm if an alarm is installed
- Allow the car to reach the lowest electrical consumption, see **TYPE CURVES, STAND-BY CURRENT** for stand-by current.

NOTE: Do not open any doors or the test will have to be restarted from the beginning.

- Remove the fuse for the alarm siren
- After approximately 12 minutes, the power consumption should have reached its lowest level, <22 mA for an unalarmed car and <35 mA for an alarmed car.

CONNECTING THE MEASURING INSTRUMENT

When measuring the power consumption, it will soon become evident if there is power consuming component in the car drawing an excessive amount of the battery capacity. If it is obvious that the car is using more current than the listed limits, check the fuse of each power consuming component. See **STAND-BY CURRENT, CONSUMPTION VALUE** .

The curves and graphs supplied should be seen as guide values. The consumption may vary depending on the level of equipment in the car. The contents are for a car with the full equipment level, although not including customer installed power consuming components.

Two different methods of measuring total standby power consumption are described below. The simplest and surest method is to use crocodile clips or battery isolator with multimeter. This minimizes the risk of blowing the instrument's internal fuse and is a simpler way of making the connection.

The car's standby consumption can be measured one of two ways depending on whether you have an instrument with or without crocodile clips. The first alternative below is for an instrument with crocodile clips. The second alternative can be performed with a multimeter.

MEASUREMENT METHOD

The battery negative terminal must be connected to measure the total power consumption.

HINT: First select Option 1.

OPTION 1. CONNECTING CROCODILE CLIPS AND THE MULTIMETER

Fig. 2: Crocodile Clips And Multimeter
Courtesy of VOLVO CARS CORPORATION

- Set the crocodile clips and the measuring instrument/multimeter to 10A. Secure the crocodile clips to the

battery negative terminal.

Reading off and measuring the total stand-by current

- Read off the power consumption and compare with, see **TYPE CURVES, STAND-BY CURRENT**.
- **HINT: In order to ensure accuracy when taking the reading, change to a lower measurement range as the power consumption falls. See TYPE CURVES, STAND-BY CURRENT for stand-by current consumption.**
- The total stand-by current should be <22 mA for an unalarmed car and <35 mA for an alarmed car
- Return the car to its normal status if the stand-by current is OK
- If the result is >25 mA for an unalarmed car or >35 mA for an alarmed car, continue to **MEASURING AND FAULT-TRACING THE STAND-BY CURRENT PER FUSE**.

NOTE: Do not forget to unlock the boot lid or tailgate.

OPTION 2. CONNECTING THE MEASURING INSTRUMENT/MULTIMETER AND NEGATIVE BATTERY TERMINAL

NOTE: To avoid current surges that could damage the measuring instrument when the battery lead is connected, carry out the following.

- Disconnect the battery negative lead. See **BATTERY, DISCONNECTING** .

Fig. 3: Connecting Multimeter To Negative Battery Terminal And Ground Cable
Courtesy of VOLVO CARS CORPORATION

Set the measuring instrument/multimeter to 10 A.

NOTE: Check that the connections are secure. If the circuit is broken, the stand-by current must be re-checked from the beginning.

Fig. 4: Detaching Ground Cable From Negative Terminal
Courtesy of VOLVO CARS CORPORATION

Connect the measuring instrument to the negative battery terminal and ground cable. Connect the ground cable to the body.

Reading off and measuring the total stand-by current

- Detach the ground cable from the negative terminal.
- Read off the standby current consumption and compare with the type curves in, see **TYPE CURVES, STAND-BY CURRENT**.
- **HINT: In order to ensure accuracy when taking the reading, change to a lower measurement range as the power consumption falls. See TYPE CURVES, STAND-BY CURRENT for stand-by current consumption.**
- The total stand-by current should be <22 mA for an unalarmed car and <35 mA for an alarmed car
- Return the car to its normal status if the stand-by current is OK
- If the result is >25 mA for an unalarmed car or >35 mA for an alarmed car, continue to **MEASURING AND FAULT-TRACING THE STAND-BY CURRENT PER FUSE**.

NOTE: Do not forget to unlock the boot lid or tailgate.

MEASURING AND FAULT-TRACING THE STAND-BY CURRENT PER FUSE

NOTE: If the car is using considerably more current (>20%) than the value shown in the standby current curve, there may be a component fault in the car. For type curves, see TYPE CURVES, STAND-BY CURRENT. Readings should only be taken per fuse if the power consumption exceeds the curve by >20%.

When taking readings with the fuses in place, it is important to ensure that the system fed by the fuse is still carrying current during connection.

- Close and lock the doors (except for the driver's door) and the tailgate or boot lid. Arm the alarm if installed

- Check that all the lighting is switched off

Fig. 5: Using Screwdriver To Lock Driver's Side Door Lock
Courtesy of VOLVO CARS CORPORATION

- Use a screwdriver to lock the driver's side door lock
- After approximately 12 minutes, the electrical/power consumption should have reached its lowest level, <22 mA for an unalarmed car and <25 mA for an alarmed car.

Fig. 6: Connecting Instrument To Terminal Pin On Reverse Of Fuse
Courtesy of VOLVO CARS CORPORATION

- Expose the fuse/fusebox. See **INTEGRATED RELAY/FUSEBOX, ENGINE COMPARTMENT, REPLACING**.
- Set the measuring instrument to the correct range. Connect the instrument to the terminal pin on the reverse of the fuse
- Remove the fuse
- Read off the stand-by current consumption for the relevant component. Compare the value with, see **STAND-BY CURRENT, CONSUMPTION VALUE** .
- Install the fuse and then disconnect the measuring instrument
- Repeat the reading until the faulty component has been localised
- Return the car to its normal status if the stand-by current consumption is OK.

NOTE: Do not forget to unlock doors and the boot lid or tailgate.

FAULT-TRACING AND TESTING THE ELECTRICAL GENERATING SYSTEM AND POWER CONSUMING COMPONENTS (2005-12)

FAULT-TRACING AND TESTING THE VOLTAGE SUPPLY SYSTEM

Check the battery, starter motor and generator terminals and cables for loose, corroded or damaged cable terminals and wiring.

Check the generator (GEN) charge current and charge voltage.

Ensure that the freewheeling generator pulley functions correctly (where applicable):

- Rev the engine to 3,000 rpm. No extra electrical consumers should be switched on.
- Switch off the engine. Check that the generator rotates for longer than the engine.

In cold weather, the battery warning lamp in the combined instrument panel may light up for a few seconds after start. This is because the freewheel may require a few revolutions to heat up the bearing grease. A battery warning lamp which is continuously lit may indicate a freewheel which does not lock against the generator (GEN) rotor shaft.

Check the auxiliary belt tension. Inspect the belt for wear.

Measure the vehicle's stand by voltage consumption (below).

Measuring the stand-by current consumption

see **CHECKING STANDBY CURRENT**

Calculating the maximum permissible stand-by voltage

Identify the capacity of the battery in the car in order to calculate the maximum permitted stand-by voltage.

Formula

*Ah / 504 h / 4 = I mA

(* = the battery capacity, I = the stand-by current)

E. g.:

capacity / 3 weeks * 25% = stand by voltage

65 Ah / 504 h * 0.25 =32.2 mA

FAULT-TRACING BATTERIES (2003-12)

FAULT-TRACING AND TESTING THE BATTERY

NOTE: **As the graphics in this service information are used for different model years and / or models, some variation may occur. However, the essential information in the graphics is always correct.**

WARNING: **Oxyhydrogen is formed when batteries are being charged. Oxyhydrogen is extremely explosive. Smoking, welding, grinding and naked flames in the vicinity of the battery may result in the battery exploding causing personal injury and damage to the car. Only charge the battery in a well ventilated area. Ensure that ventilation is good**

WARNING: **Watch out for acid splash The battery contains sulfuric acid which can cause serious corrosive damage. If the electrolyte comes into contact with your eyes, skin or clothes - flush using large quantities of water. Contact a doctor immediately if acid splashes into eyes Use protective goggles when handling batteries.**

CLEANING AND CHECKING BATTERIES

CLEANING AND CHECKING BATTERIES EXTERNALLY

Fig. 1: Identifying Battery
Courtesy of VOLVO CARS CORPORATION

Cleaning

- Remove the battery from the car. Always disconnect the negative terminal first to prevent sparking
- Check that the battery is clean. Dirt can cause leakage currents between the battery posts
- Wash the battery using water. A mild cleaning agent can be used if necessary. Ensure that no dirt or water penetrates any of the cells
- Wipe clean and dry.

External checks

- Check the battery for signs of the following damage and remedy as necessary:
  - Dirty or loose posts
  - The battery is not secure and is loose in the engine compartment or cargo compartment
  - Worn, oxidized or damaged battery leads.
- Discard the battery if any of the following faults are found:
  - Cracked container
  - Leakage

  - Bent, loose or damaged terminals
  - Battery damaged by freezing.

- Reinstall the battery in the car after checking it. Connect the positive terminal first
- Check that the battery is secure in the engine compartment or cargo compartment.

WARNING: The battery can develop oxyhydrogen, which is highly explosive. Ensure that any evacuation hose (the hose which evacuates oxyhydrogen from the cargo compartment) is correctly connected to the battery and that the hose leads downwards to the dedicated outlet in the bodywork

CHECKING THE ELECTROLYTE LEVEL

Check the electrolyte level. Top up the electrolyte if necessary. To check and top up, see **BATTERY ACID LEVEL, CHECKING** .

TESTING THE BATTERY

CHOOSING THE TEST METHOD

Select the method to be used to test the battery:

NOTE: There is now a new version of Volvo Battery Analyzer, Volvo Battery Analyzer 3200 . The main difference between the 3100 and the new 3200 is that it is possible to print via an IR port on the 3200.

To print, see PRINT, VIEW OR EXPORT.

North America:

- see **TESTING WITH VOLVO BATTERY ANALYZER 3100/3200**

NOTE: North American dealers must always use Volvo Battery Analyzer 3100/3200.

- see **ALTERNATIVE TEST METHOD**

Volvo recommends that the battery is tested with the Volvo Battery Analyzer 3100/3200.

TESTING WITH VOLVO BATTERY ANALYZER 3100/3200

Fig. 2: Identifying Volvo Battery Analyzer 3100/3200
Courtesy of VOLVO CARS CORPORATION

Volvo Battery Analyzer 3100/3200 is used to test batteries as follows

Volvo Battery Analyzer 3100/3200 is used to test the battery. The following is a description of how the tool is used and the text shown in the display.

For further instructions, see the separate instruction card supplied with Volvo Battery Analyzer 3100/3200.

Setting the language

Set the language according to the instructions on the separate instruction card. English must be selected for markets where the relevant language cannot be selected for Volvo Battery Analyzer 3100/3200.

The display when testing batteries

Connect the tool cables directly to the battery.

The start window (below) is displayed for 3 seconds:

VOLVO 3100/3200 VERSION 1.0

NOTE: **The test tool must always be connected directly to the battery posts or to the cable terminals on the battery leads. The resistance of the battery leads may affect the readings and provide incorrect results if the tool is connected anywhere other than in the engine compartment.**

Scroll to select whether the test will take place inside or outside the vehicle (see the instruction card). Outside the car means that the battery is not connected to the vehicle's electrical system. Then press ENTER (see the instruction card).

NOTE: **It is important that the correct test mode is selected (inside or outside the vehicle) to obtain accurate results.**

Establish the test standard by checking the markings on the battery. CCA/SAE and DIN tests use different standards. Select the test standard. Press ENTER.

NOTE: **North American dealers must always select the CCA test**

NOTE: **It is essential that the battery markings are read correctly (i. e. whether the cold cranking amperes is listed according to the CCA/SAE or DIN standard. This is listed on the label on the battery. See BATTERY MARKING.**

SELECT MODE ^˘

GOOD-RECHARGE

xxxx V
CHARGE & RETEST

xxxx V
REPLACE BATTERY

xxxx V
BAD CELL-REPLACE

NOTE: The text describes the condition of the battery.

The voltage displayed is an indication of the charge status of the battery.

After displaying the above result, the test instrument will shift between this result and the charge status. The state of charge (%) is displayed in intervals of 25%.

NOTE: The window for the state of charge is only displayed when testing VOLVO batteries.

GOOD BATTERY

If GOOD BATTERY is displayed, the following text for the state of charge will be shown:

STATE OF CHARGE: 75-100%

GOOD-RECHARGE / CHARGE & RETEST

If GOOD-RECHARGE or CHARGE & RETEST is displayed, one of the following alternatives for the state of charge will be shown in the display:

STATE OF CHARGE: 0-25%

STATE OF CHARGE: 25-50%

STATE OF CHARGE: 50-75%

CHARGE & RETEST means that the battery must be recharged and then tested again. The battery must be discarded if the same result is obtained.

REPLACE BATTERY/BAD CELL-REPLACE

If REPLACE BATTERY or BAD CELL-REPLACE is displayed, the following text for the state of charge will be shown:

STATE OF CHARGE: REPLACE BATTERY

REPLACE BATTERY means that the battery must be discarded.

If a good connection to the battery is not obtained, the following message will be displayed. If this is the case, check the connections by working the cable terminals on the test tool forwards and backwards.

CHECK CONNECTION

ALTERNATIVE TEST METHOD

NOTE: **This method does not apply to North American dealers. North American dealers must always follow the Volvo Battery Analyzer 3100/3200 test method.**

Follow the steps below:

1. Checking the density of the acid

The density of the acid can be measured using an electrolyte gauge or a refractometer on the battery at room temperature.

Measure the density in all the cells. Check the following:

- If the density is above 1.225 g/cm^3 in each cell and the difference in density between the cells is less than 0.03 g/cm^3 , the battery must be tested for load. See point 4 below, *Load check*
- If the density is below 1.225 g/cm^3 in each cell and the difference in density between the cells is less than 0.03 g/cm^3 , the battery must be charged. See **BATTERY, CHARGING**
- If the density in two adjacent cells is considerably lower than in other cell (i. e. if the difference is greater than 0.03 g/cm^3 , there is probably leakage between the two cells. Discard the battery
- If the density is markedly lower in only one cell, the fault is probably a short-circuit. Check the battery acid for discoloration. Discard the battery.

2. Checking the stand-by voltage

Check the stand-by voltage as follows:

- Disconnect the cable from the battery negative terminal

- Leave the battery disconnected for at least 2 hours
- Measure the stand-by voltage using a digital multimeter. The battery must be recharged immediately if the stand-by voltage is lower than 12.45 V. For information about charging, see **BATTERY, CHARGING**
- If the car has not been delivered to a customer - update the Battery Maintenance Card as shown.
- Connect the battery negative terminal.

3. Charging

If the battery is not charged, it must be charged according to **BATTERY, CHARGING** .

Check that the battery takes the charge.

- If the charge is OK, the battery must be load tested. See point 4 below, *Load check*
- The battery may be sulfated if it does not charge. Sulfating means that the battery is damaged due to insufficient charge. Discard the battery.

4. Load check

During a load test, the load current must rise to at least 3 times the battery capacity in amperes (A).

For example: A battery with a capacity of 60 Ah must be loaded with a current of 180 A (= 3 x 60).

Read off the battery voltage after approximately 15 seconds. The voltage must then be 9.6 V. If this voltage is not reached there may be an open-circuit or a short-circuit in the battery.

- An **open-circuit** can be identified, for example, by the voltage dropping rapidly towards 0 V when the battery is loaded, or if the voltmeter does not give a reading when connected to the battery. Discard the battery if there is an open-circuit
- A **short-circuit** is most often evident under load when the short-circuited cell or cells begin to boil. Discard the battery if there is an short-circuit.

5. Self-discharge

If the battery has been checked according to points 1-4 above, but is not showing signs of the above faults, set the battery to self-discharge to check that the self-discharge is normal.

If the battery self-discharges abnormally and does not retain a charge for more than a couple of days, this may be a sign of a potential short-circuit. Discard the battery.

PRINT, VIEW OR EXPORT

BATTERY MARKING

Performance

The performance of a car battery is normally expressed as follows:

- Cold cranking amperes, CCA. See the explanation in, see **COLD CRANKING AMPERES**
- Reserve capacity, RC. See the explanation in, see **RESERVE CAPACITY, RC**
- Capacity, C20 (in certain cases). See the explanation in, see **CAPACITY** .

Recommended charge current

The cold cranking amperes according to the SAE and DIN norms and the corresponding capacity and recommended charge current are shown in the table below.

COLD CRANKING AMPERES ACCORDING TO THE SAE NORM AND THE CORRESPONDING CAPACITY AND RECOMMENDED CONSTANT CHARGE CURRENT

Cold cranking amperes (CCA) according to SAE	Capacity	Recommended constant charge current
420 A	45 Ah	4 A
440 A	50 Ah	4 A
520 A	50-60 Ah	5 A
600 A	65-70 Ah	6 A
680 A	90 Ah	7 A

COLD CRANKING AMPERES ACCORDING TO THE DIN NORM AND THE CORRESPONDING CAPACITY AND RECOMMENDED CONSTANT CHARGE CURRENT

Cold cranking amperes according to DIN	Capacity	Recommended constant charge current
250 A	45 Ah	4 A
310 A	63 Ah	5 A
420 A	72 Ah	7 A
590 A	60 Ah	9 A

5. Volvo part number (9459947).

*12 V is the nominal terminal voltage. This means that the battery has a stand-by voltage of 12.72 V when fully charged. Note that a battery with a stand-by voltage of 12 V is only charged to approximately 35% of capacity (see the diagram in **ACID DENSITY**).

ELECTRICAL

Battery And Mounting - General Information

ELECTRICAL CONSUMPTION, GENERAL (2003-04)

The change from traditional electrical systems with hardware based functions to flexible CAN based electrical systems where a number of nodes govern a large number of software based functions has increased the number of functions in cars. This has also caused an increase in electrical power consumption.

The generator (GEN) has been designed to supply the car with sufficient current for normal electrical loads when driving. The battery functions as a buffer for extreme loads or driving conditions. When the engine is switched off, it is the battery that supplies the car with energy.

POST DRIVING POWER CONSUMING COMPONENTS

Engine cooling fan (FC)

After driving in hot conditions, the engine cooling fan (FC) may run on for approximately 6 minutes.

Blower fan

After driving with the air conditioning (A/C) on, the blower fan may run for 8 minutes for up to 50 minutes after disengagement to remove moisture from the condenser.

Alarm siren

Note that the battery for the alarm siren starts its charging cycle after the battery poles has been disconnected and then reconnected. This means that the stand-by current consumption can reach 50 mA during the first 14 hours.

POWER CONSUMPTION

Ignition setting 0 with closed but not locked doors

Approximately 2 A, after 12 minutes approximately 20 mA (if the siren is not charging).

Ignition switch position I (radio position) with closed doors

Approximately 10 A, after 12 minutes approximately 20 mA (if the siren is not charging).

HINT: Consumption depends on factors such as the radio, interior lighting and blower fan. The power consumption can vary therefore.

Ignition switch position 0 or I with open or incorrectly closed doors

Approximately 6 A, after 12 minutes approximately 1 A (if the siren is not charging). After 20 minutes, the

interior lighting switches off and consumption drops to approximately 20 mA.

HINT: Consumption can reach more than 6 A depending on factors such as the radio, door lighting and blower fan.

Door locked and alarm on

Approximately 30 mA depending on the equipment level of the car and the accessories.

NOTE: It takes approximately 10 minutes before all nodes are closed down after the car is locked.

Other power consuming components that may be running in ignition switch positions I and II

- Blower fan; approximately 4-23 A

  NOTE: A blower fan activated at low speed is not audible in a workshop.

- Radio; approximately 1-6 A
- Low beam; approximately 9 A
- In ignition switch position II, (programming position), all CAN nodes are activated and the automatic low beam system is activated (if applicable).

BATTERY

NOTE: The power consumption in a car with the ignition switch in position I or 2 (engine off) can reach in excess of 20 A. In 30-60 minutes, more than 50% of the battery charge status can drain, at which point the plates start to sulfate which causes permanent damage to the battery and reduces its service life. Ensure wherever possible that:

- **all doors are closed correctly**
- **that low beam and the interior lighting is off**
- **the blower fan is switched off**
- **deactivate the seat heaters and rear demist.**

Connect a battery charger if the repair work allows for this. This applies even when downloading software to nodes, even if the electrical/power consumption is lower than is normal for key position II. Downloads take time, during which the entire CAN network and all associated components are activated. There is also a risk that the data transfer will fail if the system voltage falls below 10.5 V.

For further information about the function of the battery and fault-tracing, see **BATTERY, CHARGING** and **FAULT-TRACING AND TESTING THE BATTERY** .

HANDLING UNSERVICEABLE BATTERIES (2003-12)

HANDLING UNSERVICEABLE BATTERIES

Fig. 1: Handling Unserviceable Batteries
Courtesy of VOLVO CARS CORPORATION

A lead battery contains substances that are harmful to the environment and hazardous to health, such as lead and sulfuric acid. Therefore an unserviceable battery must always be recycled to avoid dangerous substances being released into the environment.

Unserviceable batteries must be treated as hazardous waste. Such batteries must be handled according to the policies of each country.

WARNING: **The battery contains sulfuric acid which can cause serious corrosive damage. If the electrolyte comes into contact with your eyes, skin or clothes - flush using large quantities of water. Contact a doctor immediately if acid splashes into eyes. Use protective goggles when handling batteries.**

BATTERY MAINTENANCE

BATTERY ACID LEVEL, CHECKING

CHECKING THE ELECTROLYTE LEVEL

Fig. 1: Checking Electrolyte Level
Courtesy of VOLVO CARS CORPORATION

Check the electrolyte level at every regular service. More regular checks may be required for cars with heavy usage or used in hot climates. **Always** check the electrolyte level both before and after charging the battery.

- Remove the battery plugs
- Check the level in all the battery cells. Each cell has its own maximum mark (A). It is recommended that a flashlight is used.
- Top up to the maximum mark (A) using distilled or deionized water. **Never use tap water** . Tap water may damage the battery.

CAUTION: Never fill above the maximum mark (A) This may cause the electrolyte to leak.

- Install plugs.

  Never switch gray plugs (with a gas release filter) with black sealed plugs

- Tighten the plugs fully.

WARNING: Remember that the battery contains oxyhydrogen . Oxyhydrogen is highly explosive . A naked flame or smoking near the battery can cause it to explode resulting in personal injury and/or damage to the car.

WARNING: The battery contains sulphuric acid . This can cause serious corrosive damage . If the electrolyte comes into contact with your eyes, skin or clothes - flush using large quantities of water. Contact a doctor immediately if acid splashes into eyes.

BATTERY, CHARGING

CHARGING BATTERIES USING A CONSTANT CHARGE CURRENT

Fig. 2: Charging Battery
Courtesy of VOLVO CARS CORPORATION

WARNING: Explosive oxyhydrogen accumulates when the battery charges. Smoking, welding, grinding or other activities involving sparks or naked flames are prohibited in the vicinity of a charging battery. Batteries must never be charged in the car. Batteries must be charged in a well ventilated place. Ensure that ventilation is good.

WARNING: Watch out for acid splash The battery contains sulphuric acid . This can cause serious corrosive damage . If the electrolyte comes into contact with your eyes, skin or clothes - flush using large quantities of water. Contact a doctor immediately if acid splashes into eyes.

CAUTION: Boost charging (using a high current) will damage the battery. Boost charging is prohibited. Never charge using a voltage in excess of 14.5 volts.

1. Checking the electrolyte level before charging

The electrolyte level must be checked before the battery is charged. See **BATTERY ACID LEVEL, CHECKING**. Never charge a battery when the electrolyte level is low.

2. Charging the battery

- Remove the battery from the car. Always disconnect the negative terminal first to prevent sparking
- Connect the battery charger to the battery terminals. Charge the battery for approximately 10 hours at the recommended constant current. For the recommended constant charge current, see the table in, see **BATTERY MARKING**.
- Reinstall the battery after charging. Connect the positive terminal first.

WARNING: **The battery can develop oxyhydrogen, which is highly explosive. Ensure that any evacuation hose (the hose which evacuates oxyhydrogen from the cargo compartment) is correctly connected to the battery and that the hose leads downwards to the dedicated outlet in the bodywork**

3. Checking the electrolyte level after charging

After charging, the electrolyte level must be checked again and topped up if necessary. See **BATTERY ACID LEVEL, CHECKING**.

Performance

The performance of a car battery is normally expressed as follows:

- Cold cranking amperes, CCA. See the explanation in, see **COLD CRANKING AMPERES**
- Reserve capacity, RC. See the explanation in, see **RESERVE CAPACITY, RC**
- Capacity, C20 (in certain cases). See the explanation in, see **CAPACITY** .

Recommended charge current

The cold cranking amperes according to the SAE and DIN norms and the corresponding capacity and recommended charge current are shown in the table below.

COLD CRANKING AMPERES ACCORDING TO THE SAE NORM AND THE CORRESPONDING CAPACITY AND RECOMMENDED CONSTANT CHARGE CURRENT

Cold cranking amperes (CCA) according to SAE	Capacity	Recommended constant charge current
420 A	45 Ah	4 A
440 A	50 Ah	4 A
520 A	50-60 Ah	5 A
600 A	65-70 Ah	6 A
680 A	90 Ah	7 A

COLD CRANKING AMPERES ACCORDING TO THE DIN NORM AND THE CORRESPONDING CAPACITY AND RECOMMENDED CONSTANT CHARGE CURRENT

Cold cranking amperes according to DIN	Capacity	Recommended constant charge current
250 A	45 Ah	4 A
310 A	63 Ah	5 A
420 A	72 Ah	7 A
590 A	60 Ah	9 A

WIRES

OPTICAL WIRING HARNESS CHECK

CHECK

NOTE: Check that special tool 9512867 is working before using it. This is done as follows.

- Select the desired socket for connection by setting the SELECTOR SWITCH to position 2+0 or 2+4.
- Connect a suitable optical test cable, with the instrument supplied, to the selected socket
- Select visual indication (green light - LED) or sound indication (buzzer - BEEP) by setting the right switch BEEP/LED in the desired position.
- Set the special tool's switch OFF/ON in position **ON** . The red light (POWER ON) shall light up.
- Press the red button (2+0 TEST or 2+4 TEST) on the lower section of the special tool which corresponds to a connected test cable. The unit now transmits a light signal through the test cable.
- The transmitted signal will be received as long as there is now a complete optical loop. If visual indication is selected, the green lamp Rx will light to indicate that the signal has been received. If sound indication is selected the buzzer will sound to indicate that the signal has been received.
- When the check is complete, set the OFF/ON switch on the special tool to position **OFF** .

The following must be carried out after repairs, checks or replacement of fiber optic wiring.

- Connect the desired connector on the MOST cable to the relevant socket on the special tool
- Select the connected socket by setting the SELECTOR SWITCH to position 2+0 or 2+4
- Set the special tool's switch OFF/ON in position **ON** . The red light (POWER ON) shall light up.
- Activate the Infotainment system.

HINT: If the infotainment system has been activated and there is not an open-circuit in the fibre optic network, the display on the infotainment control module (ICM) must be lit.

HINT: It is also possible to check visually if there is a light signal in the MOST cable from a control module in the network to the connector for the next control module without switching on the ignition. This is done by connecting the special tool to the connector on the MOST cable at the relevant control module.

- Select the socket which is connected on the special tool by setting the SELECTOR SWITCH to position 2+0 or 2+4
- Disconnect the MOST cable from the next control module
- Set the special tool's switch OFF/ON in position **ON** . The red light (POWER ON) shall light up.

- Press the red button (2+0 TEST or 2+4 TEST) on the lower section of the special tool which corresponds to a connected MOST cable. The special tool now transmits a light signal through the cable. Check that there is a red light at the next connector on the MOST cable
- When the check is complete, set the OFF/ON switch on the special tool to position **OFF** .

NOTE: **The visual check is not a verification of the function of the system. However the strength of the light signal must exceed a certain level for there to be full functionality in the system.**

Cables And Fuses - Diagnostic Trouble Codes and Associated Procedures

CEM-1A52: COMMUNICATION WITH THE DRIVER DOOR MODULE (DDM). SIGNAL MISSING (2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A52

Condition

Diagnostic trouble codes (DTCs) are stored if the central electronic module (CEM) registers that communication with the driver's door module (DDM) is not operating.

NOTE: In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network

Substitute Value

None.

Possible Source

- No power supply to the driver's door module (DDM)
- Open-circuit in the ground lead to the driver's door module (DDM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the driver's door module (DDM)
- The driver's door module (DDM) is not intended for this car (for example a used control module with different software/hardware).

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the Control area network.

Fault symptom[s]

- Does not lock / unlock a door
- The driver's door switch panel does not work.

SIGNAL MISSING

CHECKING THE FUNCTION OF THE DRIVER DOOR MODULE (DDM)

- Ignition off.

  Check that the fuse for the driver door module (DDM) in the passenger compartment fusebox is intact.

  Connect a voltmeter between the power supply cable to the control module and ground.

The voltage between the control module power cable and ground must be battery voltage when the ignition is off.

Check the cable between the control module and ground: the left or right front seat support. Check for a short-circuit to ground. Check for an open-circuit.

SIGNAL MISSING

GENERAL INFORMATION

HINT: For general information about fault-tracing the control area network (CAN), see the linked document below. See GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK (2005-2012)

In order to check the control area network (CAN) cables, the resistance in the network must be measured. The resistance between the two CAN cables, with the network connected, must be 60ohms in both the high speed network and the low speed network.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

If diagnostic trouble codes (DTCs) can be read off from the relevant control module, the fault is probably intermittent. The locations that must be checked in the event of a fault in the low speed network are the junctions behind the central electronic module (CEM) and the audio module (AUM) as well as the cable harness behind the Audio module (AUM).

Intermittent fault in the current supply to the actual control module is indicated by the DTC in the Central electronic module (CEM) (CEM-1A5X or CEM-1A6X). There is probably no diagnostic trouble code (DTC) in the relevant control module as the control module cannot store a diagnostic trouble code (DTC) when it is without power.

- **Continue**

  Refer to **CHECKING THE RESISTANCE OF THE CONTROL AREA NETWORK (CAN) CABLES**

CHECKING THE RESISTANCE OF THE CONTROL AREA NETWORK (CAN) CABLES

Fig. 8: Identifying Ignition In Off Position And Disconnecting Negative Cable From Battery
Courtesy of VOLVO CARS CORPORATION

- Disconnect the battery negative lead. The network must not be powered when taking resistance readings. Otherwise an incorrect value may be obtained.
- Connect the adapter wiring to the central electronic module (CEM).

  HINT: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

  When taking readings on the low speed network

  - When taking readings on the low speed network the adapter wiring should be connected to the Central electronic module (CEM) and readings taken from there. Readings can even be taken in the connector for the Power seat module (PSM). The advantage of the adapter wiring to the Central electronic module (CEM) is that all control module can be connected in the network when taking readings and access can be gained to both the high speed and low speed networks.

    The resistance reading only measures the main arteries in the low speed network, not the junctions that exist for different control modules.

  When taking readings on the high speed network

  - When taking readings on the high speed network the adapter wiring should be connected to the Engine control module (ECM) and readings taken from there. The Engine control module (ECM) must be connected. This resistance reading only measures the main arteries in the high speed network.

  Connect an ohmmeter to the terminals for CAN-L and CAN-H on the relevant network. Turn the contacts and turn the cable harness. Resistance must be approximately 60 ohms.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

Fig. 9: Checking For Open Circuit
Courtesy of VOLVO CARS CORPORATION

Is the value OK?

- **YES**

  Refer to **CHECKING A SHORT-CIRCUIT IN CAN CABLES**

- **NO**

  Refer to **IDENTIFYING FAULT CAUSES IN THE CAN NETWORK**

CHECKING A SHORT-CIRCUIT IN CAN CABLES

Connect an ohmmeter between respective CAN cable and voltage supply and between the CAN cables and ground. Turn the contacts and turn the cable harness. The resistance must be infinite or very high.

HINT: Readings can be taken from one and the same connector if the CAN wiring, voltage supply and ground is pre-routed. If possible, measure from the rear of the affected connectors in order to minimize any damage and future loose connections. If this is not possible, use the adapter wiring or loose terminal pin for good contact.

Was a fault detected?

- **YES**

  Refer to **IDENTIFYING FAULT CAUSES IN THE CAN NETWORK**

- **NO**

  Refer to **CHECKING THE TRAFFIC LOAD ON THE CAN CABLES**

CHECKING THE TRAFFIC LOAD ON THE CAN CABLES

Fig. 10: Identifying Ignition ON
Courtesy of VOLVO CARS CORPORATION

- Connect the battery.
- Ignition on.

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

The following applies for model year -2004:

Connect a voltmeter between CAN-L and ground. The voltage shall be approx. 2.3 V.

Then connect a voltmeter between CAN-H and ground. The voltage shall be approx. 2.8 V.

The following applies for model year 2004-:

Connect a voltmeter between CAN-L and ground. The voltage should be approx: V

Connect a voltmeter between CAN-H and ground. The voltage should be approx: V

NOTE: **For vehicles of later model years, normal voltage values lie within a specific interval due to increased traffic between the control modules on the CAN network upon update of the electrical system.**

HINT: If possible, measure from the rear of the affected connectors so that they are not damaged.

Other information

- see **BATTERY, DISCONNECTING**

Is the value OK?

- **YES**

  Refer to **INFORMATION**

- **NO**

  Refer to **IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK**

IDENTIFYING FAULT CAUSES IN THE CAN NETWORK

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an short-circuit between on of the CAN cables and voltage or ground, the fault can be localized disconnecting a control module that splits the CAN network. Readings can then be taken to determine on which side the fault is on the disconnected control module.

  Connect an ohmmeter between the CAN cable and voltage supply respectively ground. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. The resistance must be infinite or very high (more than 1 Mohms).

  If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

  HINT: A short-circuit between the CAN cables and supply voltage or ground may be in either the wiring or in a control module.

Remedy the cables as necessary. If a fault is found on one control module, replace the control module.

- **Continue**

  Refer to **VERIFICATION**

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

Fig. 11: Identifying Ignition ON
Courtesy of VOLVO CARS CORPORATION

- Connect the battery.
- Ignition on.

  If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to

an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

The following applies for model year -2004:

Connect a voltmeter between the CAN cables. In the event of correct communication on the network, the average value of the voltage must be approximately 0.5 V (0.4 V to 0.6 V).

The following applies for model year 2004-:The following applies for model year 2004-:

Connect a voltmeter between the CAN cables. During correct CAN network communication, voltage should be about 0.6-1.4 V.

NOTE: For vehicles of later model years, the normal voltage value is slightly higher due to increased traffic between the control modules on the CAN network upon update of the electrical system.

In the event of a communication fault the voltage is significantly higher than the above specified values. In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

HINT: When the probable faulty control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced. Remedy as necessary.

NOTE: After a fault with "interfering" control modules, other control modules may remain in "Limp-Home mode" even when the ignition has been switched off and on several times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

IDENTIFYING FAULT CAUSES IN THE CAN NETWORK

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an open-circuit on, or short-circuit between the CAN cables, the fault can be localized by disconnecting a control module that splits the CAN network. Readings can then be taken to determine on which side the fault is on the disconnected control module.

  Connect an ohmmeter between the CAN cables. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. Resistance should be 120 ohms.

  If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

  Remedy the cables as necessary.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A53

Condition

Fig. 14: Identifying Driver's Door Module
Courtesy of VOLVO CARS CORPORATION

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the passenger door module (PDM) is not operating.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

NOTE: **In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN)**

Substitute Value

- None.

Possible Source

- No power supply to passenger door module (PDM)
- Open-circuit in the ground lead for the passenger door module (PDM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the passenger door module (PDM)
- The passenger door module (PDM) is not intended for this vehicle (for example a used control module with different software/hardware).

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the controller area network (CAN).

Fault symptom[s]

- Does not lock / unlock a door.
- The passenger door switch panel does not work.

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

- **General about CAN-related diagnostic trouble codes:**

  CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

  CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

  XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

  XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

  NOTE: In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

  NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

  If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

- Ignition off
- Disconnect the battery negative lead

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For LS-CAN, terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

CHECKING THE AMOUNT OF TRAFFIC ON THE LS-CAN

Fig. 23: Identifying Ignition On Position
Courtesy of VOLVO CARS CORPORATION

- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #11 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-**

TRACING IN THE CAN NETWORK

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #3 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.

- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. Fig. 31: Identifying Ignition On Position

- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module

in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

Carry out the following:

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

GENERAL INFORMATION

HINT: For general information about fault-tracing the control area network (CAN), see the linked document below. See GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK (2005-2012)

In order to check the control area network (CAN) cables, the resistance in the network must be measured. The resistance between the two CAN cables, with the network connected, must be 60ohms in both the high speed network and the low speed network.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

If diagnostic trouble codes (DTCs) can be read off from the relevant control module, the fault is probably intermittent. The locations that must be checked in the event of a fault in the low speed network are the junctions behind the central electronic module (CEM) and the audio module (AUM) as well as the cable harness behind the Audio module (AUM).

Intermittent fault in the current supply to the actual control module is indicated by the DTC in the Central electronic module (CEM) (CEM-1A5X or CEM-1A6X). There is probably no diagnostic trouble code (DTC) in the relevant control module as the control module cannot store a diagnostic trouble code (DTC) when it is without power.

  Refer to **CHECKING THE RESISTANCE OF THE CONTROL AREA NETWORK (CAN) CABLES**

CHECKING THE RESISTANCE OF THE CONTROL AREA NETWORK (CAN) CABLES

- Disconnect the battery negative lead. The network must not be powered when taking resistance readings. Otherwise an incorrect value may be obtained.
- Connect the adapter wiring to the central electronic module (CEM).

HINT: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

When taking readings on the low speed network

- When taking readings on the low speed network the adapter wiring should be connected to the Central electronic module (CEM) and readings taken from there. Readings can even be taken in the connector for the Power seat module (PSM). The advantage of the adapter wiring to the Central electronic module (CEM) is that all control module can be connected in the network when taking readings and access can be gained to both the high speed and low speed networks.

  The resistance reading only measures the main arteries in the low speed network, not the junctions that exist for different control modules.

When taking readings on the high speed network

- When taking readings on the high speed network the adapter wiring should be connected to the Engine control module (ECM) and readings taken from there. The Engine control module (ECM) must be connected. This resistance reading only measures the main arteries in the high speed network.

Connect an ohmmeter to the terminals for CAN-L and CAN-H on the relevant network. Turn the contacts and turn the cable harness. Resistance must be approximately 60 ohms.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

CHECKING A SHORT-CIRCUIT IN CAN CABLES

Connect an ohmmeter between respective CAN cable and voltage supply and between the CAN cables and ground. Turn the contacts and turn the cable harness. The resistance must be infinite or very high.

HINT: Readings can be taken from one and the same connector if the CAN wiring, voltage supply and ground is pre-routed. If possible, measure from the rear of the affected connectors in order to minimize any damage and future loose connections. If this is not possible, use the adapter wiring or loose terminal pin for good contact.

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

The following applies for model year -2004:

Connect a voltmeter between CAN-L and ground. The voltage shall be approx. 2.3 V.

Then connect a voltmeter between CAN-H and ground. The voltage shall be approx. 2.8 V.

The following applies for model year 2004-:

Connect a voltmeter between CAN-L and ground. The voltage should be approx: V

Connect a voltmeter between CAN-H and ground. The voltage should be approx: V

NOTE: **For vehicles of later model years, normal voltage values lie within a specific interval due to increased traffic between the control modules on the CAN network upon update of the electrical system.**

HINT: If possible, measure from the rear of the affected connectors so that they are not damaged.

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an short-circuit between on of the CAN cables and voltage or ground, the fault can be localized disconnecting a control module that splits the CAN network. Readings can then be taken to determine on which side the fault is on the disconnected control module.

  Connect an ohmmeter between the CAN cable and voltage supply respectively ground. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. The resistance must be infinite or very high (more than 1 Mohms).

  If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

  HINT: A short-circuit between the CAN cables and supply voltage or ground may be in either the wiring or in a control module.

  If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to

an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

The following applies for model year -2004:

Connect a voltmeter between the CAN cables. In the event of correct communication on the network, the average value of the voltage must be approximately 0.5 V (0.4 V to 0.6 V).

The following applies for model year 2004-:The following applies for model year 2004-:

Connect a voltmeter between the CAN cables. During correct CAN network communication, voltage should be about 0.6-1.4 V.

NOTE: For vehicles of later model years, the normal voltage value is slightly higher due to increased traffic between the control modules on the CAN network upon update of the electrical system.

In the event of a communication fault the voltage is significantly higher than the above specified values. In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

HINT: When the probable faulty control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced. Remedy as necessary.

NOTE: After a fault with "interfering" control modules, other control modules may remain in "Limp-Home mode" even when the ignition has been switched off and on several times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

CEM-1A54: COMMUNICATION WITH THE POWER SEAT MODULE (PSM). SIGNAL MISSING (2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A54

Condition

Diagnostic trouble codes (DTCs) are stored if the central electronic module (CEM) registers that communication with the power seat module (PSM) is not operating.

NOTE: In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network

Substitute Value

None.

Possible Source

- No power supply to the power seat module (PSM)
- Open-circuit in the ground lead to the power seat module (PSM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the power seat module (PSM)
- The power seat module (PSM) is not intended for this car (for example a used control module with different software/hardware).

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the Control area network.

GENERAL INFORMATION

HINT: For general information about fault-tracing the control area network (CAN), see the linked document below. See GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK (2005-2012)

In order to check the control area network (CAN) cables, the resistance in the network must be measured. The resistance between the two CAN cables, with the network connected, must be 60ohms in both the high speed network and the low speed network.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

If diagnostic trouble codes (DTCs) can be read off from the relevant control module, the fault is probably intermittent. The locations that must be checked in the event of a fault in the low speed network are the junctions behind the central electronic module (CEM) and the audio module (AUM) as well as the cable harness behind the Audio module (AUM).

Intermittent fault in the current supply to the actual control module is indicated by the DTC in the Central electronic module (CEM) (CEM-1A5X or CEM-1A6X). There is probably no diagnostic trouble code (DTC) in the relevant control module as the control module cannot store a diagnostic trouble code (DTC) when it is without power.

- Disconnect the battery negative lead. The network must not be powered when taking resistance readings. Otherwise an incorrect value may be obtained.
- Connect the adapter wiring to the central electronic module (CEM).

HINT: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

When taking readings on the low speed network

- When taking readings on the low speed network the adapter wiring should be connected to the Central electronic module (CEM) and readings taken from there. Readings can even be taken in the connector for the Power seat module (PSM). The advantage of the adapter wiring to the Central electronic module (CEM) is that all control module can be connected in the network when taking readings and access can be gained to both the high speed and low speed networks.

  The resistance reading only measures the main arteries in the low speed network, not the junctions that exist for different control modules.

When taking readings on the high speed network

- When taking readings on the high speed network the adapter wiring should be connected to the Engine control module (ECM) and readings taken from there. The Engine control module (ECM) must be connected. This resistance reading only measures the main arteries in the high speed network.

Connect an ohmmeter to the terminals for CAN-L and CAN-H on the relevant network. Turn the contacts and turn the cable harness. Resistance must be approximately 60 ohms.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see: GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK

- **General about CAN-related diagnostic trouble codes:**

  CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

  CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

  XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

  XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

  NOTE: In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

  NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

  If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For LS-CAN, terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. CHECKING THE AMOUNT OF TRAFFIC ON THE LS-CAN

Fig. 67: Identifying Ignition On Position

- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #11 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

TRACING IN THE CAN NETWORK

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #3 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.

- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. - Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module

in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

Carry out the following:

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A55

Condition

Fig. 77: Climate Control Module
Courtesy of VOLVO CARS CORPORATION

Diagnostic trouble codes (DTCs) are stored if the central electronic module (CEM) registers that communication with the climate control module (CCM) is not operating.

NOTE: **In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network**

Substitute Value

None.

Possible Source

- No power supply to climate control module (CCM)
- Open-circuit in the ground lead to the climate control module (CCM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the climate control module (CCM)
- The climate control module (CCM) is not intended for this car (for example a used control module with different software/hardware).

NOTE: **In the event of missing CAN communication, but with the power supply still on, the climate control module (CCM) will function for a few minutes after the key has been removed (Limp-home function).**

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the Control area network.

GENERAL INFORMATION

HINT: For general information about fault-tracing the control area network (CAN), see the linked document below. See GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK (2005-2012)

In order to check the control area network (CAN) cables, the resistance in the network must be measured. The resistance between the two CAN cables, with the network connected, must be 60ohms in both the high speed network and the low speed network.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

If diagnostic trouble codes (DTCs) can be read off from the relevant control module, the fault is probably intermittent. The locations that must be checked in the event of a fault in the low speed network are the junctions behind the central electronic module (CEM) and the audio module (AUM) as well as the cable harness behind the Audio module (AUM).

Intermittent fault in the current supply to the actual control module is indicated by the DTC in the Central electronic module (CEM) (CEM-1A5X or CEM-1A6X). There is probably no diagnostic trouble code (DTC) in the relevant control module as the control module cannot store a diagnostic trouble code (DTC) when it is without power.

- Disconnect the battery negative lead. The network must not be powered when taking resistance readings. Otherwise an incorrect value may be obtained.
- Connect the adapter wiring to the central electronic module (CEM).

HINT: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

When taking readings on the low speed network

- When taking readings on the low speed network the adapter wiring should be connected to the Central electronic module (CEM) and readings taken from there. Readings can even be taken in the connector for the Power seat module (PSM). The advantage of the adapter wiring to the Central electronic module (CEM) is that all control module can be connected in the network when taking readings and access can be gained to both the high speed and low speed networks.

  The resistance reading only measures the main arteries in the low speed network, not the junctions that exist for different control modules.

When taking readings on the high speed network

- When taking readings on the high speed network the adapter wiring should be connected to the Engine control module (ECM) and readings taken from there. The Engine control module (ECM) must be connected. This resistance reading only measures the main arteries in the high speed network.

Connect an ohmmeter to the terminals for CAN-L and CAN-H on the relevant network. Turn the contacts and turn the cable harness. Resistance must be approximately 60 ohms.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

CHECKING A SHORT-CIRCUIT IN CAN CABLES

Connect an ohmmeter between respective CAN cable and voltage supply and between the CAN cables and ground. Turn the contacts and turn the cable harness. The resistance must be infinite or very high.

HINT: Readings can be taken from one and the same connector if the CAN wiring, voltage supply and ground is pre-routed. If possible, measure from the rear of the affected connectors in order to minimize any damage and future loose connections. If this is not possible, use the adapter wiring or loose terminal pin for good contact.

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

The following applies for model year -2004:

Connect a voltmeter between CAN-L and ground. The voltage shall be approx. 2.3 V.

Then connect a voltmeter between CAN-H and ground. The voltage shall be approx. 2.8 V.

The following applies for model year 2004-:

Connect a voltmeter between CAN-L and ground. The voltage should be approx: V

Connect a voltmeter between CAN-H and ground. The voltage should be approx: V

NOTE: **For vehicles of later model years, normal voltage values lie within a specific interval due to increased traffic between the control modules on the CAN network upon update of the electrical system.**

HINT: If possible, measure from the rear of the affected connectors so that they are not damaged.

- **NO**

  Refer to **IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK**

IDENTIFYING FAULT CAUSES IN THE CAN NETWORK

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an short-circuit between on of the CAN cables and voltage or ground, the fault can be localized disconnecting a control module that splits the CAN network. Readings can then be taken to determine on which side the fault is on the disconnected control module.

  Connect an ohmmeter between the CAN cable and voltage supply respectively ground. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. The resistance must be infinite or very high (more than 1 Mohms).

  If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

  HINT: A short-circuit between the CAN cables and supply voltage or ground may be in either the wiring or in a control module.

Remedy the cables as necessary. If a fault is found on one control module, replace the control module.

  If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to

an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

The following applies for model year -2004:

Connect a voltmeter between the CAN cables. In the event of correct communication on the network, the average value of the voltage must be approximately 0.5 V (0.4 V to 0.6 V).

The following applies for model year 2004-:The following applies for model year 2004-:

Connect a voltmeter between the CAN cables. During correct CAN network communication, voltage should be about 0.6-1.4 V.

NOTE: For vehicles of later model years, the normal voltage value is slightly higher due to increased traffic between the control modules on the CAN network upon update of the electrical system.

In the event of a communication fault the voltage is significantly higher than the above specified values. In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

HINT: When the probable faulty control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced. Remedy as necessary.

NOTE: After a fault with "interfering" control modules, other control modules may remain in "Limp-Home mode" even when the ignition has been switched off and on several times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see: GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK

- **General about CAN-related diagnostic trouble codes:**

  CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

  CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

  XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

  XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

  NOTE: In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

  NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

  If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For LS-CAN, terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. CHECKING THE AMOUNT OF TRAFFIC ON THE LS-CAN

Fig. 98: Identifying Ignition On Position

- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #11 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-**

TRACING IN THE CAN NETWORK

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #3 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.

- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. - Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module

in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

Carry out the following:

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

Diagnostic trouble codes (DTCs) are stored if the central electronic module (CEM) registers that communication with the driver information module (DIM) is not operating.

NOTE: **In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network**

Substitute Value

None.

Possible Source

- No power supply to the driver information module (DIM)
- Open-circuit in the ground lead to the driver information module (DIM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the drive information module (DIM)
- The driver information module (DIM) is not intended for this car (for example a used control module with different software/hardware).

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the Control area network.

GENERAL INFORMATION

HINT: For general information about fault-tracing the control area network (CAN), see the linked document below. See GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK (2005-2012)

In order to check the control area network (CAN) cables, the resistance in the network must be measured. The resistance between the two CAN cables, with the network connected, must be 60ohms in both the high speed network and the low speed network.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

If diagnostic trouble codes (DTCs) can be read off from the relevant control module, the fault is probably intermittent. The locations that must be checked in the event of a fault in the low speed network are the junctions behind the central electronic module (CEM) and the audio module (AUM) as well as the cable harness behind the Audio module (AUM).

Intermittent fault in the current supply to the actual control module is indicated by the DTC in the Central electronic module (CEM) (CEM-1A5X or CEM-1A6X). There is probably no diagnostic trouble code (DTC) in the relevant control module as the control module cannot store a diagnostic trouble code (DTC) when it is without power.

- Disconnect the battery negative lead. The network must not be powered when taking resistance readings. Otherwise an incorrect value may be obtained.
- Connect the adapter wiring to the central electronic module (CEM).

  HINT: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

  When taking readings on the low speed network

  - When taking readings on the low speed network the adapter wiring should be connected to the Central electronic module (CEM) and readings taken from there. Readings can even be taken in the connector for the Power seat module (PSM). The advantage of the adapter wiring to the Central electronic module (CEM) is that all control module can be connected in the network when taking readings and access can be gained to both the high speed and low speed networks.

    The resistance reading only measures the main arteries in the low speed network, not the junctions that exist for different control modules.

  When taking readings on the high speed network

  - When taking readings on the high speed network the adapter wiring should be connected to the Engine control module (ECM) and readings taken from there. The Engine control module (ECM) must be connected. This resistance reading only measures the main arteries in the high speed network.

  Connect an ohmmeter to the terminals for CAN-L and CAN-H on the relevant network. Turn the contacts and turn the cable harness. Resistance must be approximately 60 ohms.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

Connect an ohmmeter between respective CAN cable and voltage supply and between the CAN cables and ground. Turn the contacts and turn the cable harness. The resistance must be infinite or very high.

HINT: Readings can be taken from one and the same connector if the CAN wiring, voltage supply and ground is pre-routed. If possible, measure from the rear of the affected connectors in order to minimize any damage and future loose connections. If this is not possible, use the adapter wiring or loose terminal pin for good contact.

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

The following applies for model year -2004:

Connect a voltmeter between CAN-L and ground. The voltage shall be approx. 2.3 V.

Then connect a voltmeter between CAN-H and ground. The voltage shall be approx. 2.8 V.

The following applies for model year 2004-:

Connect a voltmeter between CAN-L and ground. The voltage should be approx: V

Connect a voltmeter between CAN-H and ground. The voltage should be approx: V

NOTE: **For vehicles of later model years, normal voltage values lie within a specific interval due to increased traffic between the control modules on the CAN network upon update of the electrical system.**

HINT: If possible, measure from the rear of the affected connectors so that they are not damaged.

Other information

- see **BATTERY, DISCONNECTING**

Is the value OK?

- **YES**

  Refer to **INFORMATION**

- **NO**

  Refer to **IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK**

IDENTIFYING FAULT CAUSES IN THE CAN NETWORK

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an short-circuit between on of the CAN cables and voltage or ground, the fault can be localized disconnecting a control module that splits the CAN network. Readings can then be taken to determine on which side the fault is on the disconnected control module.

  Connect an ohmmeter between the CAN cable and voltage supply respectively ground. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. The resistance must be infinite or very high (more than 1 Mohms).

  If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

  HINT: A short-circuit between the CAN cables and supply voltage or ground may be in either the wiring or in a control module.

Remedy the cables as necessary. If a fault is found on one control module, replace the control module.

- **Continue**

  Refer to **VERIFICATION**

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

Fig. 118: Identifying Ignition ON
Courtesy of VOLVO CARS CORPORATION

- Connect the battery.
- Ignition on.

  If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to

an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

The following applies for model year -2004:

Connect a voltmeter between the CAN cables. In the event of correct communication on the network, the average value of the voltage must be approximately 0.5 V (0.4 V to 0.6 V).

The following applies for model year 2004-:The following applies for model year 2004-:

Connect a voltmeter between the CAN cables. During correct CAN network communication, voltage should be about 0.6-1.4 V.

NOTE: For vehicles of later model years, the normal voltage value is slightly higher due to increased traffic between the control modules on the CAN network upon update of the electrical system.

In the event of a communication fault the voltage is significantly higher than the above specified values. In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

HINT: When the probable faulty control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced. Remedy as necessary.

NOTE: After a fault with "interfering" control modules, other control modules may remain in "Limp-Home mode" even when the ignition has been switched off and on several times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

IDENTIFYING FAULT CAUSES IN THE CAN NETWORK

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an open-circuit on, or short-circuit between the CAN cables, the fault can be localized by disconnecting a control module that splits the CAN network. Readings can then be taken to determine on which side the fault is on the disconnected control module.

  Connect an ohmmeter between the CAN cables. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. Resistance should be 120 ohms.

  If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

  Remedy the cables as necessary.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A56

Condition

Fig. 121: Driver Information Module
Courtesy of VOLVO CARS CORPORATION

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the driver information module (DIM) is not operating.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

NOTE: **In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN).**

Substitute Value

- None.

Possible Source

- No power supply to the driver information module (DIM)
- Open-circuit in the ground lead for the driver information module (DIM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the drive information module (DIM)
- The driver information module (DIM) is not intended for this vehicle (for example a used control module with different software/hardware).

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the controller area network (CAN).

Fault symptom[s]

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see: GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK

- **General about CAN-related diagnostic trouble codes:**

  CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

  CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

  XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

  XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

  NOTE: In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

  NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For LS-CAN, terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. CHECKING THE AMOUNT OF TRAFFIC ON THE LS-CAN

Fig. 128: Identifying Ignition On Position
Courtesy of VOLVO CARS CORPORATION

- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #11 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-**

TRACING IN THE CAN NETWORK

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #3 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.

- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. Fig. 136: Identifying Ignition On Position

- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module

in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

Carry out the following:

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

OPEN-CIRCUIT IN THE CAN BUS. LOW SPEED NETWORK. PERMANENT FAULT

CHECKING THE LOW SPEED NETWORK

The fault source on the bus cable may be a long way from where the check is carried out. Therefore start the check at one end of the cable and work through the bus system methodically until the fault is found. Disconnecting the connector from the control module splits the bus cable into two parts. If the resistance does not correspond to the given value (60 or 120 Ohm) when examining one of the components, the fault is localized in that component.

Information

- The resistance must be approximately 60 ohms when taking readings on a connected CAN
- The resistance must be approximately 120 ohms when taking readings on a CAN that is not connected.

Check the bus cable. Check for an open-circuit according to **OPEN-CIRCUIT, PERMANENT FAULTS** . Remember that the CAN bus is only a communication network. There are no fuses, contact breakers or sensors.

HINT: If the fault is detected before all the following cables have been examined, the following cables need not be checked.

HINT: If possible measure from the rear of the affected connectors so that they are not damaged.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A58

Condition

Fig. 146: Identifying Radio And Car Phone
Courtesy of VOLVO CARS CORPORATION

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the phone module (PHM) is not operating.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

NOTE: **In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN).**

Substitute Value

- None.

Possible Source

- No power supply to the phone module (PHM)
- Open-circuit in the ground lead for the phone module (PHM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the phone module (PHM)
- The phone module (PHM) is not intended for this vehicle (for example a used control module with different software/hardware).

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the controller area network (CAN).

Fault symptom[s]

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see: GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK

- **General about CAN-related diagnostic trouble codes:**

  CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

  CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

  XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

  XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

  NOTE: In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

  NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For LS-CAN, terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

FAULT-TRACING IN THE CAN NETWORK

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #11 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and

check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #3 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.

- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. Fig. 161: Identifying Ignition On Position
Courtesy of VOLVO CARS CORPORATION

- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module

in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

Carry out the following:

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

  CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

  XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

  XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

  NOTE: In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

  NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For LS-CAN, terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. - Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #11 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

TRACING IN THE CAN NETWORK

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #3 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.

- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. - Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module

in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

Carry out the following:

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

CEM-1A5A: COMMUNICATION WITH THE REAR ELECTRONIC MODULE (REM). SIGNAL MISSING (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A5A

Condition

Fig. 189: Identifying Central Electronic Module (CEM)
Courtesy of VOLVO CARS CORPORATION

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the rear electronic module (REM) is not operating.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

NOTE: **In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN).**

Substitute Value

- None.

Possible Source

- Damaged fuse F5 in the Rear electronic module (REM).
- No power supply to rear electronic module (REM)
- Open-circuit in the ground lead for the rear electronic module (REM)
- Contact resistance in the terminals

- Open-circuit in the wiring for the CAN low speed network to the rear electronic module (REM)
- The rear electronic module (REM) is not intended for this vehicle (for example a used control module with different software/hardware).

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the controller area network (CAN).

Fault symptom[s]

- The fuel gauge indicates zero even though there is fuel in the tank.
- Rear de-mist does not operate.
- Retractable headrest not operating.
- The central locking system does not function at all.
- No unlocking of the trunk lid.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #3 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.

- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module

in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

Carry out the following:

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

CEM-1A5A: COMMUNICATION WITH THE REAR ELECTRONIC MODULE (REM). SIGNAL MISSING (2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A5A

Condition

Fig. 207: Central Electronic Module Control module
Courtesy of VOLVO CARS CORPORATION

Diagnostic trouble codes (DTCs) are stored if the central electronic module (CEM) registers that communication with the rear electronic module (REM) is not operating.

NOTE: In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network

Substitute Value

None.

Possible Source

- No power supply to rear electronic module (REM)
- Open-circuit in the ground lead to the rear electronic module (REM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the rear electronic module (REM)
- The rear electronic module (REM) is not intended for this car for example a used control module with different software/hardware).

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the Control area network.

Fault symptom[s]

- The fuel indicator indicates the minimum value even though there is fuel in the tank
- Rear de-mist does not operate
- Retractable headrest not operating
- No locking/unlocking of rear doors

- No unlocking of trunk lid
- The power window mechanism in the rear door does not operate.

GENERAL INFORMATION

HINT: For general information about fault-tracing the control area network (CAN), see the linked document below. See GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK (2005-2012)

In order to check the control area network (CAN) cables, the resistance in the network must be measured. The resistance between the two CAN cables, with the network connected, must be 60ohms in both the high speed network and the low speed network.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

If diagnostic trouble codes (DTCs) can be read off from the relevant control module, the fault is probably intermittent. The locations that must be checked in the event of a fault in the low speed network are the junctions behind the central electronic module (CEM) and the audio module (AUM) as well as the cable harness behind the Audio module (AUM).

Intermittent fault in the current supply to the actual control module is indicated by the DTC in the Central electronic module (CEM) (CEM-1A5X or CEM-1A6X). There is probably no diagnostic trouble code (DTC) in the relevant control module as the control module cannot store a diagnostic trouble code (DTC) when it is without power.

- Disconnect the battery negative lead. The network must not be powered when taking resistance readings. Otherwise an incorrect value may be obtained.
- Connect the adapter wiring to the central electronic module (CEM).

  HINT: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

  When taking readings on the low speed network

  - When taking readings on the low speed network the adapter wiring should be connected to the Central electronic module (CEM) and readings taken from there. Readings can even be taken in the connector for the Power seat module (PSM). The advantage of the adapter wiring to the Central electronic module (CEM) is that all control module can be connected in the network when taking readings and access can be gained to both the high speed and low speed networks.

    The resistance reading only measures the main arteries in the low speed network, not the junctions that exist for different control modules.

  When taking readings on the high speed network

  - When taking readings on the high speed network the adapter wiring should be connected to the Engine control module (ECM) and readings taken from there. The Engine control module (ECM) must be connected. This resistance reading only measures the main arteries in the high speed network.

  Connect an ohmmeter to the terminals for CAN-L and CAN-H on the relevant network. Turn the contacts and turn the cable harness. Resistance must be approximately 60 ohms.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

CHECKING A SHORT-CIRCUIT IN CAN CABLES

Connect an ohmmeter between respective CAN cable and voltage supply and between the CAN cables and ground. Turn the contacts and turn the cable harness. The resistance must be infinite or very high.

HINT: Readings can be taken from one and the same connector if the CAN wiring, voltage supply and ground is pre-routed. If possible, measure from the rear of the affected connectors in order to minimize any damage and future loose connections. If this is not possible, use the adapter wiring or loose terminal pin for good contact.

- Connect the battery.
- Ignition on.

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

The following applies for model year -2004:

Connect a voltmeter between CAN-L and ground. The voltage shall be approx. 2.3 V.

Then connect a voltmeter between CAN-H and ground. The voltage shall be approx. 2.8 V.

The following applies for model year 2004-:

Connect a voltmeter between CAN-L and ground. The voltage should be approx: V

Connect a voltmeter between CAN-H and ground. The voltage should be approx: V

NOTE: **For vehicles of later model years, normal voltage values lie within a specific interval due to increased traffic between the control modules on the CAN network upon update of the electrical system.**

HINT: If possible, measure from the rear of the affected connectors so that they are not damaged.

- **NO**

  Refer to **IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK**

IDENTIFYING FAULT CAUSES IN THE CAN NETWORK

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an short-circuit between on of the CAN cables and voltage or ground, the fault can be localized disconnecting a control module that splits the CAN network. Readings can then be taken to determine on which side the fault is on the disconnected control module.

  Connect an ohmmeter between the CAN cable and voltage supply respectively ground. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. The resistance must be infinite or very high (more than 1 Mohms).

  If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

  HINT: A short-circuit between the CAN cables and supply voltage or ground may be in either the wiring or in a control module.

Remedy the cables as necessary. If a fault is found on one control module, replace the control module.

- **Continue**

  Refer to **VERIFICATION**

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

Fig. 218: Identifying Ignition ON

- Connect the battery.
- Ignition on.

  If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to

an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

The following applies for model year -2004:

Connect a voltmeter between the CAN cables. In the event of correct communication on the network, the average value of the voltage must be approximately 0.5 V (0.4 V to 0.6 V).

The following applies for model year 2004-:The following applies for model year 2004-:

Connect a voltmeter between the CAN cables. During correct CAN network communication, voltage should be about 0.6-1.4 V.

NOTE: For vehicles of later model years, the normal voltage value is slightly higher due to increased traffic between the control modules on the CAN network upon update of the electrical system.

In the event of a communication fault the voltage is significantly higher than the above specified values. In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

HINT: When the probable faulty control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced. Remedy as necessary.

NOTE: After a fault with "interfering" control modules, other control modules may remain in "Limp-Home mode" even when the ignition has been switched off and on several times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

CEM-1A5B: COMMUNICATION WITH THE STEERING WHEEL MODULE (SWM). SIGNAL MISSING (2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A5B

Condition

Fig. 1: Identifying Steering Wheel Module
Courtesy of VOLVO CARS CORPORATION

Diagnostic trouble codes (DTCs) are stored if the central electronic module (CEM) registers that communication with the steering wheel module (SWM) is not operating.

NOTE: **In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network**

Substitute Value

None.

Possible Source

- No power supply to the steering wheel module (SWM)
- Open-circuit in the ground lead to the steering wheel module (SWM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the steering wheel module (SWM)
- The steering wheel module (SWM) is not intended for this car for example a used control module with different software/hardware).

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the Control area network.

Fault symptom[s]

- Cruise control does not function at all
- Windshield wipers only operate at lowest speed
- The turn signal lamps are not operating
- Buttons on the steering wheel are not working.

GENERAL INFORMATION

HINT: For general information about fault-tracing the control area network (CAN), see the linked document below. See GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK (2005-2012)

In order to check the control area network (CAN) cables, the resistance in the network must be measured. The resistance between the two CAN cables, with the network connected, must be 60ohms in both the high speed network and the low speed network.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

If diagnostic trouble codes (DTCs) can be read off from the relevant control module, the fault is probably intermittent. The locations that must be checked in the event of a fault in the low speed network are the junctions behind the central electronic module (CEM) and the audio module (AUM) as well as the cable harness behind the Audio module (AUM).

Intermittent fault in the current supply to the actual control module is indicated by the DTC in the Central electronic module (CEM) (CEM-1A5X or CEM-1A6X). There is probably no diagnostic trouble code (DTC) in the relevant control module as the control module cannot store a diagnostic trouble code (DTC) when it is without power.

- Disconnect the battery negative lead. The network must not be powered when taking resistance readings. Otherwise an incorrect value may be obtained.
- Connect the adapter wiring to the central electronic module (CEM).

  HINT: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

  When taking readings on the low speed network

  - When taking readings on the low speed network the adapter wiring should be connected to the Central electronic module (CEM) and readings taken from there. Readings can even be taken in the connector for the Power seat module (PSM). The advantage of the adapter wiring to the Central electronic module (CEM) is that all control module can be connected in the network when taking readings and access can be gained to both the high speed and low speed networks.

    The resistance reading only measures the main arteries in the low speed network, not the junctions that exist for different control modules.

  When taking readings on the high speed network

  - When taking readings on the high speed network the adapter wiring should be connected to the Engine control module (ECM) and readings taken from there. The Engine control module (ECM) must be connected. This resistance reading only measures the main arteries in the high speed network.

  Connect an ohmmeter to the terminals for CAN-L and CAN-H on the relevant network. Turn the contacts and turn the cable harness. Resistance must be approximately 60 ohms.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

Connect an ohmmeter between respective CAN cable and voltage supply and between the CAN cables and ground. Turn the contacts and turn the cable harness. The resistance must be infinite or very high.

HINT: Readings can be taken from one and the same connector if the CAN wiring, voltage supply and ground is pre-routed. If possible, measure from the rear of the affected connectors in order to minimize any damage and future loose connections. If this is not possible, use the adapter wiring or loose terminal pin for good contact.

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

The following applies for model year -2004:

Connect a voltmeter between CAN-L and ground. The voltage shall be approx. 2.3 V.

Then connect a voltmeter between CAN-H and ground. The voltage shall be approx. 2.8 V.

The following applies for model year 2004-:

Connect a voltmeter between CAN-L and ground. The voltage should be approx: V

Connect a voltmeter between CAN-H and ground. The voltage should be approx: V

NOTE: **For vehicles of later model years, normal voltage values lie within a specific interval due to increased traffic between the control modules on the CAN network upon update of the electrical system.**

HINT: If possible, measure from the rear of the affected connectors so that they are not damaged.

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an short-circuit between on of the CAN cables and voltage or ground, the fault can be localized disconnecting a control module that splits the CAN network. Readings can then be taken to determine on which side the fault is on the disconnected control module.

  Connect an ohmmeter between the CAN cable and voltage supply respectively ground. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. The resistance must be infinite or very high (more than 1 Mohms).

  If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

  HINT: A short-circuit between the CAN cables and supply voltage or ground may be in either the wiring or in a control module.

Remedy the cables as necessary. If a fault is found on one control module, replace the control module.

- **Continue**

  Refer to **VERIFICATION**

- Connect the battery.
- Ignition on.

  If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to

an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

The following applies for model year -2004:

Connect a voltmeter between the CAN cables. In the event of correct communication on the network, the average value of the voltage must be approximately 0.5 V (0.4 V to 0.6 V).

The following applies for model year 2004-:The following applies for model year 2004-:

Connect a voltmeter between the CAN cables. During correct CAN network communication, voltage should be about 0.6-1.4 V.

NOTE: For vehicles of later model years, the normal voltage value is slightly higher due to increased traffic between the control modules on the CAN network upon update of the electrical system.

In the event of a communication fault the voltage is significantly higher than the above specified values. In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

HINT: When the probable faulty control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced. Remedy as necessary.

NOTE: After a fault with "interfering" control modules, other control modules may remain in "Limp-Home mode" even when the ignition has been switched off and on several times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

  If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

  HINT: A short-circuit between the CAN cables and supply voltage or ground may be in either the wiring or in a control module.

Remedy the cables as necessary. If a fault is found on one control module, replace the control module.

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

- Connect the battery.
- Ignition on.

  If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to

an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

The following applies for model year -2004:

Connect a voltmeter between the CAN cables. In the event of correct communication on the network, the average value of the voltage must be approximately 0.5 V (0.4 V to 0.6 V).

The following applies for model year 2004-:The following applies for model year 2004-:

Connect a voltmeter between the CAN cables. During correct CAN network communication, voltage should be about 0.6-1.4 V.

NOTE: For vehicles of later model years, the normal voltage value is slightly higher due to increased traffic between the control modules on the CAN network upon update of the electrical system.

In the event of a communication fault the voltage is significantly higher than the above specified values. In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

HINT: When the probable faulty control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced. Remedy as necessary.

NOTE: After a fault with "interfering" control modules, other control modules may remain in "Limp-Home mode" even when the ignition has been switched off and on several times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

IDENTIFYING FAULT CAUSES IN THE CAN NETWORK

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an open-circuit on, or short-circuit between the CAN cables, the fault can be localized by disconnecting a control module that splits the CAN network. Readings can then be taken to determine on which side the fault is on the disconnected control module.

  Connect an ohmmeter between the CAN cables. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. Resistance should be 120 ohms.

  If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

  Remedy the cables as necessary.

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see: GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK

- **General about CAN-related diagnostic trouble codes:**

  CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

  CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

  XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

  XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

  NOTE: In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

  NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

  If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.

  Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the

Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For LS-CAN, terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. CHECKING THE AMOUNT OF TRAFFIC ON THE LS-CAN

Fig. 37: Identifying Ignition On Position
Courtesy of VOLVO CARS CORPORATION

- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #11 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

TRACING IN THE CAN NETWORK

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times.   - #3 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.

- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Fig. 45: Identifying Ignition On Position

- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module

in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

Carry out the following:

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the steering wheel angle sensor module (SAS) is not operating.

The steering wheel angle sensor module (SAS) is located inside, and is supplied with power by, the steering wheel module (SWM). Only the steering wheel angle sensor module (SAS) communicates on the controller area network (CAN).

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

NOTE: **In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN)**

Substitute Value

- None.

Possible Source

GENERAL INFORMATION

HINT: For general information about fault-tracing the control area network (CAN), see the linked document below. See GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK (2005-2012)

In order to check the control area network (CAN) cables, the resistance in the network must be measured. The resistance between the two CAN cables, with the network connected, must be 60ohms in both the high speed network and the low speed network.

NOTE: Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.

If diagnostic trouble codes (DTCs) can be read off from the relevant control module, the fault is probably intermittent. The locations that must be checked in the event of a fault in the low speed network are the junctions behind the central electronic module (CEM) and the audio module (AUM) as well as the cable harness behind the Audio module (AUM).

Intermittent fault in the current supply to the actual control module is indicated by the DTC in the Central electronic module (CEM) (CEM-1A5X or CEM-1A6X). There is probably no diagnostic trouble code (DTC) in the relevant control module as the control module cannot store a diagnostic trouble code (DTC) when it is without power.

- Disconnect the battery negative lead. The network must not be powered when taking resistance readings. Otherwise an incorrect value may be obtained.
- Connect the adapter wiring to the central electronic module (CEM).

HINT: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

When taking readings on the low speed network

- When taking readings on the low speed network the adapter wiring should be connected to the Central electronic module (CEM) and readings taken from there. Readings can even be taken in the connector for the Power seat module (PSM). The advantage of the adapter wiring to the Central electronic module (CEM) is that all control module can be connected in the network when taking readings and access can be gained to both the high speed and low speed networks.

  The resistance reading only measures the main arteries in the low speed network, not the junctions that exist for different control modules.

When taking readings on the high speed network

- When taking readings on the high speed network the adapter wiring should be connected to the Engine control module (ECM) and readings taken from there. The Engine control module (ECM) must be connected. This resistance reading only measures the main arteries in the high speed network.

Connect an ohmmeter to the terminals for CAN-L and CAN-H on the relevant network. Turn the contacts and turn the cable harness. Resistance must be approximately 60 ohms.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

Connect an ohmmeter between respective CAN cable and voltage supply and between the CAN cables and ground. Turn the contacts and turn the cable harness. The resistance must be infinite or very high.

HINT: Readings can be taken from one and the same connector if the CAN wiring, voltage supply and ground is pre-routed. If possible, measure from the rear of the affected connectors in order to minimize any damage and future loose connections. If this is not possible, use the adapter wiring or loose terminal pin for good contact.

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

The following applies for model year -2004:

Connect a voltmeter between CAN-L and ground. The voltage shall be approx. 2.3 V.

Then connect a voltmeter between CAN-H and ground. The voltage shall be approx. 2.8 V.

The following applies for model year 2004-:

Connect a voltmeter between CAN-L and ground. The voltage should be approx: V

Connect a voltmeter between CAN-H and ground. The voltage should be approx: V

NOTE: **For vehicles of later model years, normal voltage values lie within a specific interval due to increased traffic between the control modules on the CAN network upon update of the electrical system.**

HINT: If possible, measure from the rear of the affected connectors so that they are not damaged.

IDENTIFYING FAULT CAUSES IN THE CAN NETWORK

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an short-circuit between on of the CAN cables and voltage or ground, the fault can be localized disconnecting a control module that splits the CAN network. Readings can then be taken to determine on which side the fault is on the disconnected control module.

  Connect an ohmmeter between the CAN cable and voltage supply respectively ground. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. The resistance must be infinite or very high (more than 1 Mohms).

  If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

  HINT: A short-circuit between the CAN cables and supply voltage or ground may be in either the wiring or in a control module.

Remedy the cables as necessary. If a fault is found on one control module, replace the control module.

- Connect the battery.
- Ignition on.

  If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to

an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

The following applies for model year -2004:

Connect a voltmeter between the CAN cables. In the event of correct communication on the network, the average value of the voltage must be approximately 0.5 V (0.4 V to 0.6 V).

The following applies for model year 2004-:The following applies for model year 2004-:

Connect a voltmeter between the CAN cables. During correct CAN network communication, voltage should be about 0.6-1.4 V.

NOTE: For vehicles of later model years, the normal voltage value is slightly higher due to increased traffic between the control modules on the CAN network upon update of the electrical system.

In the event of a communication fault the voltage is significantly higher than the above specified values. In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

HINT: When the probable faulty control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced. Remedy as necessary.

NOTE: After a fault with "interfering" control modules, other control modules may remain in "Limp-Home mode" even when the ignition has been switched off and on several times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see: GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK

- **General about CAN-related diagnostic trouble codes:**

  CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

  CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

  XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

  XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

  NOTE: In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

  NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

  If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.

  Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the

Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For HS-CAN the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules.**

Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times.   Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #14 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with.

  Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

  Carry out the following:

  Measure voltage between the following connections on the OBDII-box/diagnostics socket.

  - #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
  - #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be

lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

CEM-1A5E: COMMUNICATION WITH THE STEERING WHEEL ANGLE SENSOR MODULE (SAS). SIGNAL MISSING (B8444S; 2005-2011)

SIGNAL MISSING

CHECKING THE POWER SUPPLY AND GROUND FOR THE STEERING WHEEL MODULE (SWM)

NOTE: **Steering wheel angle sensor module (SAS) is located inside, and is supplied with power by, the steering wheel module (SWM). Only the steering wheel angle sensor module (SAS) communicates on the controller area network (CAN). The brake control module (BCM) will store a diagnostic trouble code (DTC) if the communication between the brake control module (BCM) and the steering wheel angle sensor module (SAS) has been interrupted. DSTC will not be activated after a fault in the system has been repaired until the vehicle reaches a speed of approximately 50 km/h.**

Check that the fuse for the control module is intact.

Check the power supply and ground for the steering wheel module (SWM) as follows.

Remedy as necessary.

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see: GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK

- **General about CAN-related diagnostic trouble codes:**

  CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

  CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

  XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

  XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

  NOTE: In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

  NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

  If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.

  Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the

Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For HS-CAN the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules.**

Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

CHECKING THE TRAFFIC LOAD ON THE CAN CABLES

Fig. 82: Identifying Ignition On Position
Courtesy of VOLVO CARS CORPORATION

- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #14 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.
  - #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with.

  Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

  Carry out the following:

  Measure voltage between the following connections on the OBDII-box/diagnostics socket.

  - #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
  - #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be

lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

CEM-1A5F: COMMUNICATION WITH THE BRAKE CONTROL MODULE (BCM). SIGNAL MISSING (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A5F

Condition

Fig. 92: ABS Control Module
Courtesy of VOLVO CARS CORPORATION

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the brake control module (BCM) is not operating.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

NOTE: **In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN)**

Substitute Value

- None.

Possible Source

- No power supply to the brake control module (BCM)
- Open-circuit in the ground lead to the brake control module (BCM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN high speed network to the brake control module (BCM)
- The brake control module (BCM) is not intended for this vehicle, for example a used control module with different software/hardware.

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the high speed network, this indicates a common fault in the Control area network.

Fault symptom[s]

- ABS warning lamp lit.
- No ABS function
- Message in the display.

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see: GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK

- **General about CAN-related diagnostic trouble codes:**

CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

NOTE: **In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.
  - #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. - Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with.

  Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

  Carry out the following:

  Measure voltage between the following connections on the OBDII-box/diagnostics socket.

  - #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
  - #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be

lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see: GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK

- **General about CAN-related diagnostic trouble codes:**

CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

NOTE: **In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #14. The resistance should be approx. 55 - 65 ohms.
  - If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
  - If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.

- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For HS-CAN the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules.**

Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. CHECKING THE TRAFFIC LOAD ON THE CAN CABLES

Fig. 121: Identifying Ignition On Position

- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #14 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with.

  Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

  Carry out the following:

  Measure voltage between the following connections on the OBDII-box/diagnostics socket.

  - #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
  - #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be

lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

CEM-1A5F: COMMUNICATION WITH THE BRAKE CONTROL MODULE. SIGNAL MISSING (2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A5F

Condition

Fig. 131: Brake Control Module
Courtesy of VOLVO CARS CORPORATION

Diagnostic trouble codes (DTCs) are stored if the central electronic module (CEM) registers that communication with the brake control module (BCM) is not operating.

NOTE: **In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network**

Substitute Value

No ABS function.

Possible Source

- No power supply to the brake control module (BCM)
- Open-circuit in the ground lead to the brake control module (BCM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN high speed network to the brake control module (BCM)
- The brake control module (BCM) is not intended for this car (for example a used control module with different software/hardware).

HINT: If several diagnostic trouble codes (DTCs) are generated in the central electronic module (CEM) for communication errors with other control modules in the high speed network, this indicates a common fault in the Control area network.

Fault symptom[s]

- The ABS warning lamp is lit
- No ABS function
- Message in the display.

  Check the fuses in the fusebox in the engine compartment (30-supply) for the brake control module (BCM).

  NOTE: If any fuses are blown, check the circuit after the fuse for a short-circuit to ground before replacing the fuse. Then replace the fuse.

  Check the fuse in the fusebox in the passenger compartment (15-supply) for the brake control module (BCM).

  If the fuse is blown, check the cable between the brake control module (BCM) and the fuse. Check for a short-circuit to ground.

If the fuse is intact, check the cable between the control module and the fuse. Check for an open-circuit.

Check the ground lead between the control module and the ground terminal. Check for an open-circuit. Also check the ground terminal. Check for contact resistance and oxidation.

GENERAL INFORMATION

HINT: For general information about fault-tracing the control area network (CAN), see the linked document below. See GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK (2005-2012)

In order to check the control area network (CAN) cables, the resistance in the network must be measured. The resistance between the two CAN cables, with the network connected, must be 60ohms in both the high speed network and the low speed network.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

If diagnostic trouble codes (DTCs) can be read off from the relevant control module, the fault is probably intermittent. The locations that must be checked in the event of a fault in the low speed network are the junctions behind the central electronic module (CEM) and the audio module (AUM) as well as the cable harness behind the Audio module (AUM).

Intermittent fault in the current supply to the actual control module is indicated by the DTC in the Central electronic module (CEM) (CEM-1A5X or CEM-1A6X). There is probably no diagnostic trouble code (DTC) in the relevant control module as the control module cannot store a diagnostic trouble code (DTC) when it is without power.

- Disconnect the battery negative lead. The network must not be powered when taking resistance readings. Otherwise an incorrect value may be obtained.
- Connect the adapter wiring to the central electronic module (CEM).

  HINT: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

When taking readings on the low speed network

- When taking readings on the low speed network the adapter wiring should be connected to the Central electronic module (CEM) and readings taken from there. Readings can even be taken in the connector for the Power seat module (PSM). The advantage of the adapter wiring to the Central electronic module (CEM) is that all control module can be connected in the network when taking readings and access can be gained to both the high speed and low speed networks.

  The resistance reading only measures the main arteries in the low speed network, not the junctions that exist for different control modules.

When taking readings on the high speed network

- When taking readings on the high speed network the adapter wiring should be connected to the Engine control module (ECM) and readings taken from there. The Engine control module (ECM) must be connected. This resistance reading only measures the main arteries in the high speed network.

Connect an ohmmeter to the terminals for CAN-L and CAN-H on the relevant network. Turn the contacts and turn the cable harness. Resistance must be approximately 60 ohms.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

HINT: Readings can be taken from one and the same connector if the CAN wiring, voltage supply and ground is pre-routed. If possible, measure from the rear of the affected connectors in order to minimize any damage and future loose connections. If this is not possible, use the adapter wiring or loose terminal pin for good contact.

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

The following applies for model year -2004:

Connect a voltmeter between CAN-L and ground. The voltage shall be approx. 2.3 V.

Then connect a voltmeter between CAN-H and ground. The voltage shall be approx. 2.8 V.

The following applies for model year 2004-:

Connect a voltmeter between CAN-L and ground. The voltage should be approx: V

Connect a voltmeter between CAN-H and ground. The voltage should be approx: V

NOTE: For vehicles of later model years, normal voltage values lie within a specific interval due to increased traffic between the control modules on the CAN network upon update of the electrical system.

HINT: If possible, measure from the rear of the affected connectors so that they are not damaged.

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an short-circuit between on of the CAN cables and voltage or ground, the fault can be localized disconnecting a control module that splits the CAN network. Readings can then be taken to

determine on which side the fault is on the disconnected control module.

Connect an ohmmeter between the CAN cable and voltage supply respectively ground. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. The resistance must be infinite or very high (more than 1 Mohms).

If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

HINT: A short-circuit between the CAN cables and supply voltage or ground may be in either the wiring or in a control module.

- Connect the battery.
- Ignition on.

If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

The following applies for model year -2004:

Connect a voltmeter between the CAN cables. In the event of correct communication on the network, the

average value of the voltage must be approximately 0.5 V (0.4 V to 0.6 V).

The following applies for model year 2004-:The following applies for model year 2004-:

Connect a voltmeter between the CAN cables. During correct CAN network communication, voltage should be about 0.6-1.4 V.

NOTE: For vehicles of later model years, the normal voltage value is slightly higher due to increased traffic between the control modules on the CAN network upon update of the electrical system.

In the event of a communication fault the voltage is significantly higher than the above specified values. In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

HINT: When the probable faulty control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced. Remedy as necessary.

NOTE: After a fault with "interfering" control modules, other control modules may remain in "Limp-Home mode" even when the ignition has been switched off and on several times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

CEM-1A61: COMMUNICATION WITH THE TRANSMISSION CONTROL MODULE (TCM). SIGNAL MISSING (4T65 AWD; 2005-2006)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A61

Condition

Fig. 175: Identifying Transmission Control Module
Courtesy of VOLVO CARS CORPORATION

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the transmission control module (TCM) is not operating.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

NOTE: **If CEM-1A6X diagnostic trouble codes (DTCs) are stored, the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network**

Substitute Value

- None.

Possible Source

- No power supply to the transmission control module (TCM)

- Open-circuit in the ground lead to the transmission control module (TCM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN high speed network to the transmission control module (TCM)
- The transmission control module (TCM) is not intended for this vehicle, for example a used control module with different software/hardware.

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the high speed network, this indicates a common fault in the Control area network.

Fault symptom[s]

- No shifting.
- Malfunction indicator lamp (MIL) lit
- Message in the display.

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see: GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK

- **General about CAN-related diagnostic trouble codes:**

CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

NOTE: **In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #14. The resistance should be approx. 55 - 65 ohms.
  - If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
  - If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.

- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For HS-CAN the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules.**

Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

CHECKING THE TRAFFIC LOAD ON THE CAN CABLES

Fig. 183: Identifying Ignition On Position
Courtesy of VOLVO CARS CORPORATION

- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #14 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.
  - #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. - Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with.

  Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

  Carry out the following:

  Measure voltage between the following connections on the OBDII-box/diagnostics socket.

  - #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
  - #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be

lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see: GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK

- **General about CAN-related diagnostic trouble codes:**

CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

NOTE: **In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #14. The resistance should be approx. 55 - 65 ohms.
  - If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
  - If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.

- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For HS-CAN the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules.**

Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.
  - #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with.

  Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

  Carry out the following:

  Measure voltage between the following connections on the OBDII-box/diagnostics socket.

  - #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
  - #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be

lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

CEM-1A62: COMMUNICATION WITH THE ENGINE CONTROL MODULE (ECM). SIGNAL MISSING (2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A62

Condition

Fig. 210: Engine Control Module
Courtesy of VOLVO CARS CORPORATION

Diagnostic trouble codes (DTCs) are stored if the central electronic module (CEM) registers that communication with the engine control module (ECM) is not operating.

NOTE: **In the event of CEM-1A6x diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network**

Substitute Value

None.

Possible Source

- No power supply to the engine control module (ECM)
- Open-circuit in the ground lead to the engine control module (ECM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN high speed network to the engine control module (ECM)
- - The engine control module (ECM) is not intended for this car (for example a used control module with different software/hardware).

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the high speed network, this indicates a common fault in the Control area network.

Fault symptom[s]

- The starter motor turns but the engine does not start
- The engine cuts out
- Engine feels sluggish
- Malfunction indicator lamp (MIL) lit
- Message in the display.

CHECKING THE POWER SUPPLY AND GROUND FOR THE ENGINE CONTROL MODULE (ECM)

Checking the power supply

- Check the fuse for the engine control module (ECM) in the fusebox in the engine compartment. If the fuse is blown, check the circuit after the fuse. Check for a short-circuit to ground.
- Check the power supply to the engine control module (ECM). The voltage must be approximately battery voltage.

Checking the ground terminal

- Check the ground leads between the engine control module (ECM) and the ground terminal. Check for an open-circuit
- Check the ground terminal for the engine control module (ECM). Check for contact resistance and oxidation.

GENERAL INFORMATION

HINT: For general information about fault-tracing the control area network (CAN), see the linked document below. See GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK (2005-2012)

In order to check the control area network (CAN) cables, the resistance in the network must be measured. The resistance between the two CAN cables, with the network connected, must be 60ohms in both the high speed network and the low speed network.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

If diagnostic trouble codes (DTCs) can be read off from the relevant control module, the fault is probably intermittent. The locations that must be checked in the event of a fault in the low speed network are the junctions behind the central electronic module (CEM) and the audio module (AUM) as well as the cable harness behind the Audio module (AUM).

Intermittent fault in the current supply to the actual control module is indicated by the DTC in the Central electronic module (CEM) (CEM-1A5X or CEM-1A6X). There is probably no diagnostic trouble code (DTC) in the relevant control module as the control module cannot store a diagnostic trouble code (DTC) when it is without power.

- Disconnect the battery negative lead. The network must not be powered when taking resistance readings. Otherwise an incorrect value may be obtained.
- Connect the adapter wiring to the central electronic module (CEM).

  HINT: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

When taking readings on the low speed network

- When taking readings on the low speed network the adapter wiring should be connected to the Central electronic module (CEM) and readings taken from there. Readings can even be taken in the connector for the Power seat module (PSM). The advantage of the adapter wiring to the Central electronic module (CEM) is that all control module can be connected in the network when taking readings and access can be gained to both the high speed and low speed networks.

  The resistance reading only measures the main arteries in the low speed network, not the junctions that exist for different control modules.

When taking readings on the high speed network

- When taking readings on the high speed network the adapter wiring should be connected to the Engine control module (ECM) and readings taken from there. The Engine control module (ECM) must be connected. This resistance reading only measures the main arteries in the high speed network.

Connect an ohmmeter to the terminals for CAN-L and CAN-H on the relevant network. Turn the contacts and turn the cable harness. Resistance must be approximately 60 ohms.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

CHECKING A SHORT-CIRCUIT IN CAN CABLES

Connect an ohmmeter between respective CAN cable and voltage supply and between the CAN cables and ground. Turn the contacts and turn the cable harness. The resistance must be infinite or very high.

HINT: Readings can be taken from one and the same connector if the CAN wiring, voltage supply and ground is pre-routed. If possible, measure from the rear of the affected connectors in order to minimize any damage and future loose connections. If this is not possible, use the adapter wiring or loose terminal pin for good contact.

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

The following applies for model year -2004:

Connect a voltmeter between CAN-L and ground. The voltage shall be approx. 2.3 V.

Then connect a voltmeter between CAN-H and ground. The voltage shall be approx. 2.8 V.

The following applies for model year 2004-:

Connect a voltmeter between CAN-L and ground. The voltage should be approx: V

Connect a voltmeter between CAN-H and ground. The voltage should be approx: V

NOTE: For vehicles of later model years, normal voltage values lie within a specific interval due to increased traffic between the control modules on the CAN network upon update of the electrical system.

HINT: If possible, measure from the rear of the affected connectors so that they are not damaged.

  Refer to **IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK**

IDENTIFYING FAULT CAUSES IN THE CAN NETWORK

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an short-circuit between on of the CAN cables and voltage or ground, the fault can be localized disconnecting a control module that splits the CAN network. Readings can then be taken to

determine on which side the fault is on the disconnected control module.

Connect an ohmmeter between the CAN cable and voltage supply respectively ground. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. The resistance must be infinite or very high (more than 1 Mohms).

If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

HINT: A short-circuit between the CAN cables and supply voltage or ground may be in either the wiring or in a control module.

Remedy the cables as necessary. If a fault is found on one control module, replace the control module.

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

Fig. 220: Identifying Ignition ON

- Connect the battery.
- Ignition on.

If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

The following applies for model year -2004:

Connect a voltmeter between the CAN cables. In the event of correct communication on the network, the

average value of the voltage must be approximately 0.5 V (0.4 V to 0.6 V).

The following applies for model year 2004-:The following applies for model year 2004-:

Connect a voltmeter between the CAN cables. During correct CAN network communication, voltage should be about 0.6-1.4 V.

NOTE: For vehicles of later model years, the normal voltage value is slightly higher due to increased traffic between the control modules on the CAN network upon update of the electrical system.

In the event of a communication fault the voltage is significantly higher than the above specified values. In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

HINT: When the probable faulty control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced. Remedy as necessary.

NOTE: After a fault with "interfering" control modules, other control modules may remain in "Limp-Home mode" even when the ignition has been switched off and on several times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

ELECTRICAL

Cables And Fuses - Diagnostic Trouble Codes and Associated Procedures

CEM-1A62: COMMUNICATION WITH THE ENGINE CONTROL MODULE (ECM). SIGNAL MISSING (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A62

Condition

Fig. 1: Engine Control Module
Courtesy of VOLVO CARS CORPORATION

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the engine control module (ECM) is not operating.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

NOTE: **If CEM-1A6X diagnostic trouble codes (DTCs) are stored, the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network**

Substitute Value

- None.

Possible Source

- No power supply to the engine control module (ECM)
- Open-circuit in the ground lead for the engine control module (ECM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN high speed network to the engine control module (ECM)
- The engine control module (ECM) is not intended for this vehicle, for example a used control module with different software/hardware.

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the high speed network, this indicates a common fault in the Control area network.

Fault symptom[s]

- The engine does not start.
- Engine cuts out when running
- Engine feels sluggish.
- Malfunction indicator lamp (MIL) lit.
- Message in the display.

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see: GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK

- **General about CAN-related diagnostic trouble codes:**

CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

NOTE: **In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #14. The resistance should be approx. 55 - 65 ohms.
  - If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
  - If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.

- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For HS-CAN the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules.**

Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

CHECKING THE TRAFFIC LOAD ON THE CAN CABLES

Fig. 9: Identifying Ignition On Position
Courtesy of VOLVO CARS CORPORATION

- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #14 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

Fig. 11: Identifying Ignition On Position
Courtesy of VOLVO CARS CORPORATION

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.
  - #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Fig. 17: Identifying Ignition On Position

- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with.

  Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

  Carry out the following:

  Measure voltage between the following connections on the OBDII-box/diagnostics socket.

  - #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
  - #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be

lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see:

- **General about CAN-related diagnostic trouble codes:**

  CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble

codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

NOTE: **In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

- Disconnect the battery negative lead

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #14. The resistance should be approx. 55 - 65 ohms.
  - If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
  - If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.

- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For HS-CAN the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules.**

Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

CHECKING THE TRAFFIC LOAD ON THE CAN CABLES

Fig. 26: Identifying Ignition On Position
Courtesy of VOLVO CARS CORPORATION

- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #14 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.
  - #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. Fig. 34: Identifying Ignition On Position

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with.

  Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

  Carry out the following:

  Measure voltage between the following connections on the OBDII-box/diagnostics socket.

  - #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
  - #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be

lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

CEM-1A63: COMMUNICATION WITH THE ACCESSORY ELECTRONIC MODULE (AEM). SIGNAL MISSING (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A63

Condition

Fig. 36: Accessory Electronic Module
Courtesy of VOLVO CARS CORPORATION

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the accessory electronic module (AEM) is not operating.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

NOTE: **If CEM-1A6X diagnostic trouble codes (DTCs) are stored, the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network**

Substitute Value

- None.

Possible Source

- No power supply to the accessory electronic module (AEM)
- Open-circuit in the ground lead for the accessory electronic module (AEM)

- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the accessory electronic module (AEM)
- The accessory electronic module (AEM) is not intended for this vehicle, for example a used control module with different software/hardware.

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the Control area network.

Fault symptom[s]

- Accessories connected to the control module do not function.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #3 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.

- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see:

  - see **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

Carry out the following:

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

GENERAL INFORMATION

HINT: For general information about fault-tracing the control area network (CAN), see the linked document below. See GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK (2005-2012)

In order to check the control area network (CAN) cables, the resistance in the network must be measured. The resistance between the two CAN cables, with the network connected, must be 60ohms in both the high speed network and the low speed network.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

If diagnostic trouble codes (DTCs) can be read off from the relevant control module, the fault is probably intermittent. The locations that must be checked in the event of a fault in the low speed network are the junctions behind the central electronic module (CEM) and the audio module (AUM) as well as the cable harness behind the Audio module (AUM).

Intermittent fault in the current supply to the actual control module is indicated by the DTC in the Central electronic module (CEM) (CEM-1A5X or CEM-1A6X). There is probably no diagnostic trouble code (DTC) in the relevant control module as the control module cannot store a diagnostic trouble code (DTC) when it is without power.

- Disconnect the battery negative lead. The network must not be powered when taking resistance readings. Otherwise an incorrect value may be obtained.
- Connect the adapter wiring to the central electronic module (CEM).

  HINT: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

When taking readings on the low speed network

- When taking readings on the low speed network the adapter wiring should be connected to the Central electronic module (CEM) and readings taken from there. Readings can even be taken in the connector for the Power seat module (PSM). The advantage of the adapter wiring to the Central electronic module (CEM) is that all control module can be connected in the network when taking readings and access can be gained to both the high speed and low speed networks.

  The resistance reading only measures the main arteries in the low speed network, not the junctions that exist for different control modules.

When taking readings on the high speed network

- When taking readings on the high speed network the adapter wiring should be connected to the Engine control module (ECM) and readings taken from there. The Engine control module (ECM) must be connected. This resistance reading only measures the main arteries in the high speed network.

Connect an ohmmeter to the terminals for CAN-L and CAN-H on the relevant network. Turn the contacts and turn the cable harness. Resistance must be approximately 60 ohms.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

Connect an ohmmeter between respective CAN cable and voltage supply and between the CAN cables and ground. Turn the contacts and turn the cable harness. The resistance must be infinite or very high.

HINT: Readings can be taken from one and the same connector if the CAN wiring, voltage supply and ground is pre-routed. If possible, measure from the rear of the affected connectors in order to minimize any damage and future loose connections. If this is not possible, use the adapter wiring or loose terminal pin for good contact.

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

The following applies for model year -2004:

Connect a voltmeter between CAN-L and ground. The voltage shall be approx. 2.3 V.

Then connect a voltmeter between CAN-H and ground. The voltage shall be approx. 2.8 V.

The following applies for model year 2004-:

Connect a voltmeter between CAN-L and ground. The voltage should be approx: V

Connect a voltmeter between CAN-H and ground. The voltage should be approx: V

NOTE: For vehicles of later model years, normal voltage values lie within a specific interval due to increased traffic between the control modules on the CAN network upon update of the electrical system.

HINT: If possible, measure from the rear of the affected connectors so that they are not damaged.

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an short-circuit between on of the CAN cables and voltage or ground, the fault can be localized disconnecting a control module that splits the CAN network. Readings can then be taken to

determine on which side the fault is on the disconnected control module.

Connect an ohmmeter between the CAN cable and voltage supply respectively ground. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. The resistance must be infinite or very high (more than 1 Mohms).

If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

The following applies for model year -2004:

Connect a voltmeter between the CAN cables. In the event of correct communication on the network, the

average value of the voltage must be approximately 0.5 V (0.4 V to 0.6 V).

The following applies for model year 2004-:The following applies for model year 2004-:

Connect a voltmeter between the CAN cables. During correct CAN network communication, voltage should be about 0.6-1.4 V.

NOTE: For vehicles of later model years, the normal voltage value is slightly higher due to increased traffic between the control modules on the CAN network upon update of the electrical system.

In the event of a communication fault the voltage is significantly higher than the above specified values. In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

HINT: When the probable faulty control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced. Remedy as necessary.

NOTE: After a fault with "interfering" control modules, other control modules may remain in "Limp-Home mode" even when the ignition has been switched off and on several times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

- When taking readings on the high speed network the adapter wiring should be connected to the Engine control module (ECM) and readings taken from there. The Engine control module (ECM) must be connected. This resistance reading only measures the main arteries in the high speed network.

Connect an ohmmeter to the terminals for CAN-L and CAN-H on the relevant network. Turn the contacts and turn the cable harness. Resistance must be approximately 60 ohms.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

CHECKING A SHORT-CIRCUIT IN CAN CABLES

Connect an ohmmeter between respective CAN cable and voltage supply and between the CAN cables and ground. Turn the contacts and turn the cable harness. The resistance must be infinite or very high.

HINT: Readings can be taken from one and the same connector if the CAN wiring, voltage supply and ground is pre-routed. If possible, measure from the rear of the affected connectors in order to minimize any damage and future loose connections. If this is not possible, use the adapter wiring or loose terminal pin for good contact.

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

The following applies for model year -2004:

Connect a voltmeter between CAN-L and ground. The voltage shall be approx. 2.3 V.

Then connect a voltmeter between CAN-H and ground. The voltage shall be approx. 2.8 V.

The following applies for model year 2004-:

Connect a voltmeter between CAN-L and ground. The voltage should be approx: V

Connect a voltmeter between CAN-H and ground. The voltage should be approx: V

NOTE: For vehicles of later model years, normal voltage values lie within a specific interval due to increased traffic between the control modules on the CAN network upon update of the electrical system.

HINT: If possible, measure from the rear of the affected connectors so that they are not damaged.

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an short-circuit between on of the CAN cables and voltage or ground, the fault can be localized disconnecting a control module that splits the CAN network. Readings can then be taken to

determine on which side the fault is on the disconnected control module.

Connect an ohmmeter between the CAN cable and voltage supply respectively ground. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. The resistance must be infinite or very high (more than 1 Mohms).

If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

HINT: A short-circuit between the CAN cables and supply voltage or ground may be in either the wiring or in a control module.

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

Fig. 82: Identifying Ignition ON

- Connect the battery.
- Ignition on.

If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

The following applies for model year -2004:

Connect a voltmeter between the CAN cables. In the event of correct communication on the network, the

average value of the voltage must be approximately 0.5 V (0.4 V to 0.6 V).

The following applies for model year 2004-:The following applies for model year 2004-:

Connect a voltmeter between the CAN cables. During correct CAN network communication, voltage should be about 0.6-1.4 V.

NOTE: For vehicles of later model years, the normal voltage value is slightly higher due to increased traffic between the control modules on the CAN network upon update of the electrical system.

In the event of a communication fault the voltage is significantly higher than the above specified values. In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

HINT: When the probable faulty control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced. Remedy as necessary.

NOTE: After a fault with "interfering" control modules, other control modules may remain in "Limp-Home mode" even when the ignition has been switched off and on several times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the differential electronic module (DEM) is not operating.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

NOTE: **If CEM-1A6X diagnostic trouble codes (DTCs) are stored, the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network**

Substitute Value

- None.

Possible Source

- No power supply to the differential electronic module (DEM)
- Open-circuit in the ground lead for the differential electronic module (DEM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN high speed network to the differential electronic module (DEM)
- The differential electronic module (DEM) is not intended for this vehicle, for example a used control module with different software/hardware.

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the high speed network, this indicates a common fault in the Control area network.

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see:

- **General about CAN-related diagnostic trouble codes:**

  CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble

codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

NOTE: **In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #14. The resistance should be approx. 55 - 65 ohms.
  - If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
  - If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.

- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For HS-CAN the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules.**

Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. - Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #14 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with.

  Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

  Carry out the following:

  Measure voltage between the following connections on the OBDII-box/diagnostics socket.

  - #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
  - #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be

lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see:

- **General about CAN-related diagnostic trouble codes:**

  CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble

codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

NOTE: **In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #14. The resistance should be approx. 55 - 65 ohms.
  - If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
  - If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.

- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For HS-CAN the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules.**

Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #14 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.
  - #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times.   For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with.

  Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

  Carry out the following:

  Measure voltage between the following connections on the OBDII-box/diagnostics socket.

  - #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
  - #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be

lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A66

Condition

Fig. 122: Identifying Infotainment Control Module
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) checks the communication with the infotainment control module (ICM).

Diagnostic trouble codes (DTCs) are stored if the central electronic module (CEM) registers a fault in the communication with the infotainment control module (ICM).

The diagnostic trouble code (DTC) can be detected when the ignition is on for at least 10 seconds and the battery voltage is above > 10.5 volts.

NOTE: **In the event of CEM-1A6x diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network**

Substitute Value

- None.

Possible Source

- No power supply to the infotainment control module (ICM)
- Open-circuit in the ground lead to the infotainment control module (ICM)

- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the infotainment control module (ICM)
- The infotainment control module (ICM) is not intended for this car (for example a used control module with different software/hardware).

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the Control area network.

Fault symptom[s]

- The audio system display does not function.

GENERAL INFORMATION

HINT: For general information about fault-tracing the control area network (CAN), see the linked document below. See GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK (2005-2012)

In order to check the control area network (CAN) cables, the resistance in the network must be measured. The resistance between the two CAN cables, with the network connected, must be 60ohms in both the high speed network and the low speed network.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

If diagnostic trouble codes (DTCs) can be read off from the relevant control module, the fault is probably intermittent. The locations that must be checked in the event of a fault in the low speed network are the junctions behind the central electronic module (CEM) and the audio module (AUM) as well as the cable harness behind the Audio module (AUM).

Intermittent fault in the current supply to the actual control module is indicated by the DTC in the Central electronic module (CEM) (CEM-1A5X or CEM-1A6X). There is probably no diagnostic trouble code (DTC) in the relevant control module as the control module cannot store a diagnostic trouble code (DTC) when it is without power.

- Disconnect the battery negative lead. The network must not be powered when taking resistance readings. Otherwise an incorrect value may be obtained.
- Connect the adapter wiring to the central electronic module (CEM).

HINT: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

When taking readings on the low speed network

- When taking readings on the low speed network the adapter wiring should be connected to the Central electronic module (CEM) and readings taken from there. Readings can even be taken in the connector for the Power seat module (PSM). The advantage of the adapter wiring to the Central electronic module (CEM) is that all control module can be connected in the network when taking readings and access can be gained to both the high speed and low speed networks.

  The resistance reading only measures the main arteries in the low speed network, not the junctions that exist for different control modules.

When taking readings on the high speed network

- When taking readings on the high speed network the adapter wiring should be connected to the Engine control module (ECM) and readings taken from there. The Engine control module (ECM) must be connected. This resistance reading only measures the main arteries in the high speed network.

Connect an ohmmeter to the terminals for CAN-L and CAN-H on the relevant network. Turn the contacts and turn the cable harness. Resistance must be approximately 60 ohms.

NOTE: **Resistance will only be 60 ohms if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be 120 ohms.**

HINT: Readings can be taken from one and the same connector if the CAN wiring, voltage supply and ground is pre-routed. If possible, measure from the rear of the affected connectors in order to minimize any damage and future loose connections. If this is not possible, use the adapter wiring or loose terminal pin for good contact.

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

The following applies for model year -2004:

Connect a voltmeter between CAN-L and ground. The voltage shall be approx. 2.3 V.

Then connect a voltmeter between CAN-H and ground. The voltage shall be approx. 2.8 V.

The following applies for model year 2004-:

Connect a voltmeter between CAN-L and ground. The voltage should be approx: V

Connect a voltmeter between CAN-H and ground. The voltage should be approx: V

NOTE: **For vehicles of later model years, normal voltage values lie within a specific interval due to increased traffic between the control modules on the CAN network upon update of the electrical system.**

HINT: If possible, measure from the rear of the affected connectors so that they are not damaged.

Other information

- **NO**

  Refer to **IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK**

IDENTIFYING FAULT CAUSES IN THE CAN NETWORK

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an short-circuit between on of the CAN cables and voltage or ground, the fault can be localized disconnecting a control module that splits the CAN network. Readings can then be taken to determine on which side the fault is on the disconnected control module.

  Connect an ohmmeter between the CAN cable and voltage supply respectively ground. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. The resistance must be infinite or very high (more than 1 Mohms).

  If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

  HINT: A short-circuit between the CAN cables and supply voltage or ground may be in either the wiring or in a control module.

Remedy the cables as necessary. If a fault is found on one control module, replace the control module.

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

Fig. 132: Identifying Ignition ON

- Connect the battery.
- Ignition on.

  If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to

an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

The following applies for model year -2004:

Connect a voltmeter between the CAN cables. In the event of correct communication on the network, the average value of the voltage must be approximately 0.5 V (0.4 V to 0.6 V).

The following applies for model year 2004-:The following applies for model year 2004-:

Connect a voltmeter between the CAN cables. During correct CAN network communication, voltage should be about 0.6-1.4 V.

NOTE: For vehicles of later model years, the normal voltage value is slightly higher due to increased traffic between the control modules on the CAN network upon update of the electrical system.

In the event of a communication fault the voltage is significantly higher than the above specified values. In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

HINT: When the probable faulty control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced. Remedy as necessary.

NOTE: After a fault with "interfering" control modules, other control modules may remain in "Limp-Home mode" even when the ignition has been switched off and on several times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

IDENTIFYING FAULT CAUSES IN THE CAN NETWORK

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

  HINT: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

  In the event of an open-circuit on, or short-circuit between the CAN cables, the fault can be localized by disconnecting a control module that splits the CAN network. Readings can then be taken to determine on which side the fault is on the disconnected control module.

  Connect an ohmmeter between the CAN cables. Take readings from both ends of the CAN networks at the network junction. Twist and bend the cable harness to find any intermittent short-circuits. Resistance should be 120 ohms.

  If a fault can be localized in one direction, split the network at a point further on in the CAN network in the direction that the fault was discovered and take a new reading. Try to locate the fault in this way.

  Remedy the cables as necessary.

VERIFICATION

HINT: After rectifying a fault, a verification should be carried out.

- Reinstall the connectors, components etc.
- Ignition on.
- Erase diagnostic trouble codes using the VCT2000 (or appropriate scan tool).
- Start the car. Allow the vehicle to run for 10 minutes.
- Read off diagnostic trouble codes (DTCs).

Does the diagnostic trouble code (DTC) for a communication fault recur (CEM-1A5X or CEM-1A6X)?

- **YES**

  Refer to **INFORMATION**

- **NO**

  OKAY: Troubleshooting has been completed.

INFORMATION

FAULT-TRACING INFORMATION

Verification shows that the fault is no longer present. The diagnostic trouble code (DTC) was probably caused by an intermittent fault.

Fault-tracing for this diagnostic trouble code (DTC) is not followed by a verification.

You can view the information again or exit fault-tracing for this diagnostic trouble code (DTC).

INFORMATION

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

CEM-1A66: COMMUNICATION WITH THE INFOTAINMENT CONTROL MODULE (ICM). SIGNAL MISSING (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A66

Condition

Fig. 135: Identifying Infotainment Control Module
Courtesy of VOLVO CARS CORPORATION

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the infotainment control module (ICM) is not operating.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

NOTE: **If CEM-1A6X diagnostic trouble codes (DTCs) are stored, the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network**

Substitute Value

- None.

Possible Source

- No power supply to the infotainment control module (ICM)
- Open-circuit in the ground lead for the infotainment control module (ICM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the infotainment control module (ICM)
- The infotainment control module (ICM) is not intended for this vehicle, for example a used control module with different software/hardware.

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the Control area network.

Fault symptom[s]

- The audio system display does not function.
- Functions in the infotainment system do not work.

CHECKING THE FUNCTION OF THE INFOTAINMENT CONTROL MODULE (ICM)

With the ignition key in position I or II, check that the infotainment control module (ICM) is powered and grounded by checking that the button illumination for the infotainment control module (ICM) lights.

If the button illumination lights up, the infotainment control module (ICM) is powered and grounded.

CHECKING COMMUNICATION WITH THE INFOTAINMENT CONTROL MODULE (ICM)

HINT: The CAN communication with the control module is probably OK if the control module ID can be read off. In that case the fault is probably intermittent and will then be more difficult to trace.

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see:

- **General about CAN-related diagnostic trouble codes:**

  CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

  CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

  XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

  XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

  NOTE: In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

  NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

  If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.

  Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the

Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
