- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For LS-CAN, terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

CHECKING THE AMOUNT OF TRAFFIC ON THE LS-CAN

Fig. 143: Identifying Ignition On Position

- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #11 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

TRACING IN THE CAN NETWORK

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #3 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.

- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #3 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module

in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

Carry out the following:

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

CEM-1A67: COMMUNICATION WITH HCM CONTROL MODULE SIGNAL MISSING (2007-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1A67

Condition

Fig. 153: Identifying Headlight Control Module (HCM)
Courtesy of VOLVO CARS CORPORATION

The diagnostic trouble code (DTC) is generated if the central electronic module (CEM) registers that communication with the headlight control module (HCM) is not operating.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

NOTE: **If CEM-1A6X diagnostic trouble codes (DTCs) are stored, the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network**

Substitute Value

- None.

Possible Source

- Voltage feed to Headlight Control Module (HCM) missing.
- Open circuit on ground cable to Headlight Control Module (HCM)
- Contact resistance in the terminals
- Open circuit on CAN cables to headlight control module (HCM).
- Headlight Control Module (HCM) not intended for this car, e. g., used control module with other hardware/software.

HINT: If several diagnostic trouble codes for communication errors with other control modules in the high-speed network are stored in the Central electronic module (CEM), this indicates some common problem in the CAN-network.

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see:

- **General about CAN-related diagnostic trouble codes:**

  CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

  CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

  XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

  XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

  NOTE: In case of CAN-related faults, it is likely that a combination of above

diagnostic trouble codes occur.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For HS-CAN the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules.**

Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e. g., contact resistance in a connector or branching, communication may be lost/interfered with.

  Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

  Carry out the following:

  Measure voltage between the following connections on the OBDII-box/diagnostics socket.

  - #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
  - #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be

lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see:

- **General about CAN-related diagnostic trouble codes:**

  CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

  CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

  XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

  XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

NOTE: **In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.**

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For HS-CAN the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules.**

Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have**

stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

CHECKING THE TRAFFIC LOAD ON THE CAN CABLES

Fig. 180: Identifying Ignition On Position

Courtesy of VOLVO CARS CORPORATION

- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #4 (ground). The voltage should be approx:2, 8 - 3, 2 V.
- #14 and #4 (ground). The voltage should be approx:1, 8 - 2, 2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #4 (ground). Measurement is shown in the illustration. The resistance should be above 1 kohms.
  - #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #16 (voltage). Measurement is shown in the illustration. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. None.

Possible Source

- Defective generator (GEN)
- Defective battery.

Fault symptom[s]

- The "Generator not charging" warning lamp is lit when the engine is running
- The headlamp bulb blows
- The "Generator not charging" warning lamp is not lit when the ignition is switched on
- Low rotation speed in the starter motor
- The electrolyte in battery boils with the engine running
- The battery discharges.

CEM-1C06: ALTERNATOR CONTROL MODULE (ACM). ELECTRICAL FAULT (B5254T2; 2005-2007)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1C06

Condition

Fig. 218: Freewheel Generator
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) communicates with the alternator control module (ACM).

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) receives information from the alternator control module (ACM) indicating an electrical fault in the generator (GEN).

The diagnostic trouble code (DTC) can be diagnosed at engine speeds (RPM) above 600 RPM.

Substitute Value

- None.

Possible Source

- A battery charger with too high charge voltage has been connected previously
- Worn brushes (carbon)
- Damaged alternator control module (ACM)
- Damaged generator (GEN).

Fault symptom[s]

- The "Generator not charging" warning lamp is lit when the engine is running
- Warning lights and chimes/Generator warning indication/no indication
- Alternator and charge regulator/Power supply problems
- The battery discharges
- Low rotation speed in the starter motor

CHECKING BATTERY VOLTAGE

Fig. 219: Belt Routing / Engine Idling - Volvo
Courtesy of VOLVO CARS CORPORATION

- Start the engine
- Read off the battery voltage. The central electronic module (CEM) uses the prevailing outside temperature to calculate the voltage at which the battery should be charged
- Switch on a few major power consuming components, such as the blower fan.

  Check that the voltage is within the limits of 13.5-14.9 V. Try at different engine speeds (RPM).

  The fault is permanent if the voltage is outside the permitted range.

  If the voltage is within the permitted range, the fault was present previously but is not active at the moment, i. e. an intermittent fault.

CHECKING THE FREEWHEEL ON A GENERATOR (GEN)

Check the function of the free wheel as follows.

Checking the function of the freewheel on the generator (GEN) in the car

- Ensure that no extra power consuming components are connected
- Start the engine. Rev the engine to 3000 RPM
- Check that only a faint clicking sound is heard when the freewheel engages and disengages
- Quickly switch off the engine. Check that the generator rotates for longer than the engine.

NOTE: **If it is cold, the battery charge warning lamp may light shortly after start-up because the freewheel needs to rotate and warm up the bearing grease before it locks and engages the rotor shaft. If the warning lamp remains lit, it may be an indication that the freewheel has not locked the pulley to the rotor shaft.**

Checking the function of the freewheel on a removed generator (GEN)

- Rotate the pulley counter-clockwise and brake the pulley heavily. The freewheel must grip the rotor shaft when rotating counter-clockwise
- Stop the rotation by braking the pulley. When braking the pulley, the freewheel mechanism should release so that the rotor shaft continues to rotate.

Remedy as necessary.

CEM-1C22: RELAY, INFOTAINMENT. SIGNAL TOO LOW/SIGNAL MISSING (2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1C22

Condition

The central electronic module (CEM) checks the output signal to the relay coil for relay infotainment.

Diagnostic trouble code (DTC) CEM-1C22 is stored if the central electronic module (CEM) registers that the output signal to the relay coil is too low/absent.

Diagnostic trouble code (DTC) CEM-1C22 can be detected when the relay driver is not activated.

Substitute Value

PROGRAMMING DAYTIME RUNNING LAMPS

PROGRAMMING DAYTIME RUNNING LAMPS

Three different daytime running light functions can be programmed:

1. Low beam in all switch positions except the parking light position (Flex zero)

Position light switch:

OFF: Parking and daytime running lamps or Xenon lamps are activated depending on the signal from the twilight sensor.

Parking lamps: Only parking lamps activated.

On: Parking and Xenon lamps are activated.

2. The light switch functioning on the basis of: off, parking light and low beam (Flex standard)

Position light switch:

OFF: Daytime running lamps are activated. If the twilight sensor registers insufficient light, all lighting is switched off (Xenon lamps are not activated).

Parking lamps: Only parking lamps activated.

On: Parking and Xenon lamps are activated.

3. Low beam always on regardless of the position of the light switch (Flex low)

Position light switch:

OFF: Parking and daytime running lamps or Xenon lamps are activated depending on the signal from the twilight sensor.

Parking lamps: Parking and Xenon lamps are activated.

On: Parking and Xenon lamps are activated.

It is essential that the legal requirements of each country are followed.

PROGRAMMING CONTROL MODULE

PROGRAMMING PROCEDURES

The following can be programmed in the Central electronic module (CEM) according to customer's wishes.

Programming

1. Seat temperature.

   Refer to **PROGRAMMING THE SEAT TEMPERATURE (CENTRAL ELECTRONIC MODULE)**

2. Approach lights.

   Refer to **PROGRAMMING THE HOME SAFE LIGHTS**

3. Daytime running lights.

   Refer to **PROGRAMMING DAYTIME RUNNING LAMPS**

4. Tailgate window wiper (5 DRS).

   Refer to **PROGRAMMING THE WIPER FUNCTION FOR THE REAR WINDSHIELD (5 DOOR MODELS)**

PROGRAMMING THE SEAT TEMPERATURE (CENTRAL ELECTRONIC MODULE)

PROGRAMMING THE SEAT TEMPERATURE (CENTRAL ELECTRONIC MODULE)

The heated seat temperature can be adjusted.

This can be carried out for both the left and right seats.

There are two values that can be programmed: low temperature and high temperature.

Programming must be carried out so that the high temperature setting is higher than the low temperature setting.

Do you want to program in Celsius or Fahrenheit?

1. Celsius

   Refer to **CELSIUS**

2. Fahrenheit.

   Refer to **FAHRENHEIT**

CELSIUS

The seat temperature can be set between 0°C and 43°C.

Which seat do you want to reprogram:

1. Left seat

   Refer to **CHECKING THE LEFT SEAT**

2. Right seat.

   Refer to **CHECKING THE RIGHT SEAT**

FAHRENHEIT

The seat temperature can be set between 32°F and 109.4°F.

Which seat do you want to reprogram:

1. Left seat

   Refer to **CHECKING THE LEFT SEAT**

2. Right seat.

   Refer to **CHECKING THE RIGHT SEAT**

CHECKING THE LEFT SEAT

Read off the programming using the VCT2000 (or appropriate scan tool).

To change the seat temperature, mark the desired value in the scrolling list and start programming.

Programming must be carried out so that the high temperature setting is higher than the low temperature setting.

PROGRAMMING THE HOME SAFE LIGHTS

PROGRAMMING THE HOME SAFE LIGHTS

The home safe lights can be programmed to stay on for a longer or shorter time according to the wishes of the customer.

The factory setting is 30 seconds. The time can be set to 0, 30, 60 or 90 seconds.

Read off the programming using the VCT2000 (or appropriate scan tool).

To change the time set, mark the desired value in the scrolling list and start programming.

PROGRAMMING DAYTIME RUNNING LAMPS

PROGRAMMING DAYTIME RUNNING LAMPS

Three different daytime running light functions can be programmed:

1. Low beam in all switch positions except the parking light position (Flex zero)

Position light switch:

OFF: Parking and daytime running lamps or Xenon lamps are activated depending on the signal from the twilight sensor.

Parking lamps: Only parking lamps activated.

On: Parking and Xenon lamps are activated.

2. The light switch functioning on the basis of: off, parking light and low beam (Flex standard)

Position light switch:

OFF: Daytime running lamps are activated. If the twilight sensor registers insufficient light, all lighting is switched off (Xenon lamps are not activated).

Parking lamps: Only parking lamps activated.

On: Parking and Xenon lamps are activated.

3. Low beam always on regardless of the position of the light switch (Flex low)

Position light switch:

OFF: Parking and daytime running lamps or Xenon lamps are activated depending on the signal from the twilight sensor.

Parking lamps: Parking and Xenon lamps are activated.

On: Parking and Xenon lamps are activated.

It is essential that the legal requirements of each country are followed.

NOTE: It is not permitted to change this programming in the Canadian market.

Read off the programming using the VCT2000 (or appropriate scan tool).

PROGRAMMING THE WIPER FUNCTION FOR THE REAR WINDSHIELD (5 DOOR MODELS)

- The wiper function for the rear windshield can be programmed. There are two versions:

  1. The rear windshield wiper can only be activated manually.

  2. The rear windshield wiper can be activated automatically when back-up (reverse) gear is selected and the front wipers are activated.

  Read off the programming using the VCT2000 (or appropriate scan tool).

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-1D06

Condition

Fig. 67: Identifying Central Electronic Module (CEM)
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) checks the number of parameters in the vehicle configuration file is correct.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers an incorrect number of parameters in the vehicle configuration file.

The diagnostic trouble code (DTC) can be detected when the central electronic module (CEM) is initialized after a reset.

Substitute Value

- None.

Possible Source

- Incorrect number of parameters in the vehicle configuration file.

Fault symptom[s]

- None.

CONFIGURATION FAULT

CHECKING THE PROGRAMMED VALUES

Fig. 68: Identifying Ignition ON
Courtesy of VOLVO CARS CORPORATION

- Ignition on.

  The control module has registered an incorrect number of parameters in the vehicle configuration file.

  If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.

  The control module must be reprogrammed to remedy the fault.

The customer parameters must be read off, if not already been done, before the software is downloaded.

Read off and note the values.

These parameters must be re-entered using VIDA (Volvo scan tool) after programming.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers an internal fault.

The diagnostic trouble code (DTC) can be diagnosed 5 minutes after the ignition has been switched off.

Substitute Value

- None.

Possible Source

- Internal fault in the control module.

Fault symptom[s]

- No gauges are working
- The instrument lighting does not operate
- The turn signal lamps are not operating
- Poor performance.

INTERNAL FAULT

REPLACING THE COMPONENT

The central electronic module (CEM) has registered an internal fault.

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. Replace the central electronic module (CEM) if the fault recurs.

Replace the central electronic module (CEM) if the fault is permanent.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers faulty or modified software in the engine control module (ECM).

Substitute Value

- None.

Possible Source

- Faulty or modified software in the engine control module (ECM).

Fault symptom[s]

FAULTY SIGNAL

CHECKING PROGRAMMING

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.

NOTE: **The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the software in the engine control module (ECM) is faulty or modified. It is therefore important that no steps are taken to remedy modified software in the engine control module (ECM) without first consulting the customer. Neither may software be remedied if the software has been modified by the customer, but this is not the reason for the repair work.**

CEM-3F02: SHIFT LOCK SIGNAL. SIGNAL TOO HIGH (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-3F02

Condition

Fig. 189: Identifying Gearshift Lever And Linkage
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) checks the function of the shift lock.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers a short-circuit to battery voltage in the output signal for shift lock.

The relay for shift lock must be activated for the diagnostic trouble code (DTC) to be stored. The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute Value

- If the fault has been detected in 100 ignition cycles, the output is closed permanently until the diagnostic trouble code is erased (applies from structure week 200539).

Possible Source

- Short-circuit to the positive supply in the "inhibited shifting" output signal. The relay is not activated.

Fault symptom[s]

- The starter motor does not turn
- The engine does not start.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-3F03

Condition

Fig. 215: Identifying Gearshift Lever And Linkage
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) checks the function of the shift lock.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) detects a short-circuit to ground or an open-circuit in the output signal circuit to the shift lock.

The relay for shift lock must not be activated for the diagnostic trouble code (DTC) to be stored. The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.

Substitute Value

- None.

Possible Source

- Open-circuit in the "Inhibited shifting" output signal. The relay is not activated.

Fault symptom[s]

CEM-3F90: FUEL PUMP RELAY. OPEN-CIRCUIT OR SHORT-CIRCUIT TO GROUND (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-3F90

Condition

Fig. 267: Identifying Fuel Pump
Courtesy of VOLVO CARS CORPORATION

Central electronic module (CEM) checks the fuel pump relay, and activates it, when an approved check has been made by the system for Immobilizer. The fuel pump relay is located internally in the Central electronic module (CEM). The fuel pump relay sends voltage feed to the fuel pump when the relay is activated.

If Central electronic module (CEM) detects that the voltage on the output to the fuel pump is too low, the diagnostic trouble code is generated.

The diagnostic trouble code (DTC) can be diagnosed when the fuel pump is activated.

NOTE: **When troubleshooting, the fuel pump may not be supplied with voltage by an external power source without first disconnecting the connector to the Central electronic module (CEM). If the connector is not loosened and the fuel pump is supplied with voltage, this can lead to failure of an internal ground conductor in the Central electronic module (CEM). In turn, this can lead to a number of other malfunctions in the vehicle and that Central electronic module (CEM) must be replaced.**

The following applies to vehicles with fuel pump module (PEM):

Central electronic module (CEM) checks the voltage feed to the fuel pump module. The Central electronic module (CEM) activates the voltage supply to the fuel pump control module after the checks carried out by the function for the immobilizer have been approved.

If Central electronic module (CEM) detects that the voltage on the output to the fuel pump module (PEM) is too low, the diagnostic trouble code is generated.

The diagnostic trouble code (DTC) can be diagnosed when the fuel pump is activated.

Substitute Value

- None.

Possible Source

- Damaged power supply fuse.
- Open circuit on cables for voltage feed between fuse box engine compartment and Central electronic module (CEM).
- The cable for voltage feed between Central electronic module (CEM) and fuel pump module (PEM)/fuel pump is short-circuited to ground.

Fault symptom[s]

CEM-3F91: FUEL PUMP RELAY. SHORT-CIRCUIT TO SUPPLY VOLTAGE (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-3F91

Condition

Fig. 273: Identifying Fuel Pump
Courtesy of VOLVO CARS CORPORATION

Central electronic module (CEM) checks the fuel pump relay, and activates it, when an approved check has been made by the system for Immobilizer. The fuel pump relay is located internally in the Central electronic module (CEM). The fuel pump relay sends voltage feed to the fuel pump when the relay is activated.

If Central electronic module (CEM) detects that the output to the fuel pump is short-circuited to voltage, the diagnostic trouble code is generated.

The diagnostic trouble code (DTC) can be diagnosed in ignition position II and if the fuel pump relay is activated at the same time.

NOTE: Applies to vehicles to and incl. model year 2006

- **When troubleshooting, the fuel pump may not be supplied with voltage by an external power source without first disconnecting the connector to the Central electronic module (CEM). If the connector is not loosened and the fuel pump is supplied with voltage, this can lead to failure of an internal ground conductor in the Central electronic module (CEM).**

Applies to vehicles from and incl. model year 2007

- **The case with the ground cable described above does not apply to Central electronic module (CEM) from and incl. model year 2006. This diagnostic trouble code can be generated if the cable for voltage feed to the fuel pump has an open circuit or if the fuel pump is not connected.**

The following applies to vehicles with fuel pump module (PEM):

Central electronic module (CEM) checks the voltage feed to the fuel pump module. The Central electronic module (CEM) activates the voltage supply to the fuel pump control module after the checks carried out by the function for the immobilizer have been approved. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the voltage in the signal cable is too high.

The diagnostic trouble code (DTC) can be diagnosed in ignition position II and if the relay for power supply to the fuel pump control module is not activated.

Substitute Value

- None.

Possible Source

- The cable for voltage feed to the fuel pump module is short-circuited to voltage.

NOTE: Applies to vehicles to and incl. model year 2006

If the signal cable has been short-circuited to voltage, there is a risk of failure of an internal ground conductor on one of the circuit boards in the Central electronic module (CEM). This may lead to the relay for 15-feed, on Central electronic module (CEM), not working as intended. A result of incorrect function of 15-feed may be, e. g., that diagnostic trouble codes are generated for the seat heater in front seats and also that the

communication with Brake control module (BCM) doe not work when the engine is on (BCM is not supplied with voltage when the 15-relay is not grounded). The malfunction may have different effects in different vehicles, depending on the vehicle's configuration (which units that are supplied via 15-feed), but also depends on where the ground conductor has failed.

- Ignition off
- Disconnect central electronic module (CEM) connector A.

  Check the cable for a short-circuit to supply voltage.

  Take readings between:

  - Central electronic module (CEM) terminal #A16 (16) and fuel pump/fuel pump control module.

  Remedy as necessary.

Applies to vehicles to and incl. model year 2006

If the signal cable has been short-circuited to voltage, there is a risk of failure of an internal ground conductor on one of the circuit boards in the Central electronic module (CEM). This may lead to the relay for 15-feed, on Central electronic module (CEM), not working as intended. A result of incorrect function of 15-feed may be, e. g., that diagnostic trouble codes are generated for the seat heater in front seats and also that the communication with Brake control module (BCM) doe not work when the engine is on (BCM is not supplied with voltage when the 15-relay is not grounded). The malfunction may have different effects in different vehicles, depending on the vehicle's configuration (which units that are supplied via 15-feed), but also depends on where the ground conductor has failed.

REPLACING THE COMPONENT

CAUTION: A short-circuit to supply voltage may mean that the central electronic module (CEM) is damaged and must be replaced.

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. Replace the central electronic module (CEM) if the fault recurs.

Replace the central electronic module (CEM) if the fault is permanent.

Remedy as necessary.

The central electronic module (CEM) continuously checks the signal from the sensor on the ejector side which indicates the level in one of the fuel tanks.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) detects that the fuel level has not changed during the last 100 km.

The diagnostic trouble code (DTC) can be diagnosed with the ignition on and the fuel level above 2 liters.

Substitute Value

- None.

Possible Source

- The sensor on the ejector side is faulty.

Fault symptom[s]

- The trip computer displays an empty fuel tank too early.

FAULT-TRACING INFORMATION

The right camera module (RCM) has previously registered a fault but the fault no longer exists. The diagnostic trouble code (DTC) was probably generated by an intermittent fault. If the fault persists, fault-tracing according to this diagnostic trouble code (DTC) should be carried out even though no fault symptom can be detected. The seriousness of the fault is determined from case to case.

You can choose between continuing fault-tracing or ending it.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-4F43

Condition

Fig. 338: Identifying Camera Module
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) monitors communication between the blind spot indication system (BLIS) LEDs and camera modules.

If the central electronic module (CEM) detects that the signal from the left LED to the left camera module (LCM) is too high, a diagnostic trouble code is generated.

The diagnostic trouble code can be diagnosed when the ignition is on.

Substitute Value

- Nothing.

Possible Source

- The signal lead to the left LED is shorted to supply voltage.

Fault symptom[s]

- The LED does not come on.
- Light emitting diode always on.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-4F47

Condition

Fig. 370: Identifying Camera Module
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) controls communication with the blind spot indication system (BLIS) camera modules.

If the central electronic module (CEM) detects an internal fault on the left camera module (LCM) a diagnostic trouble code is generated.

The diagnostic trouble code can be diagnosed when the ignition is on.

Substitute Value

- Nothing.

Possible Source

- Dirty lens.
- Loose connection or oxidation in signal connections to Left Camera Module (LCM).
- Internal fault in left camera module (LCM).

Fault symptom[s]

- The LED does not come on.
- LED flashing rapidly.

INTERNAL FAULT

REPLACING THE COMPONENT

A diagnostic trouble code will be generated if the central electronic module (CEM) detects an internal fault in the left camera module (LCM).

If the fault is intermittent it will have been registered earlier but no longer exists. Intermittent faults could be due to interference on starting up or to another type of fault than recurs at different times. The seriousness of the fault is determined from case to case.

Remedy as necessary.

  Check the sun sensor signal by varying the intensity of the light that it detects.

  Cover the sun sensor with your hand to obtain the minimum signal, approximately 0.5 volts.

  Then direct a strong light source (for example a flashlight) at the sun sensor from close range to increase

the signal.

HINT: If the signal from the sun sensor is constantly above 4.85 volts, there is either an open-circuit in the cable or the sun sensor is defective.

NOTE: The illustration only shows the method. The appearance of the sun sensor can vary between different models.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-5A01

Condition

Fig. 401: Identifying Twilight Sensor
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) checks the signal from the sun sensor.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the signal from the sensor is too low.

The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute Value

- The control module adopts a substitute value corresponding to approximately 20% (200 W/m^2) of maximum solar heat.

Possible Source

- Short-circuit to ground in the signal cable between the control module and the sun sensor
- Damaged sun sensor.

Fault symptom[s]

- The passenger compartment temperature does not drop when the sun intensity is high.

  If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.

  Vary the light intensity. Read off the signal from the sun sensor.

Cover the sun sensor with your hand to obtain the minimum signal, approximately 0.5 volts.

CEM-5B01: LH HEATING ELEMENT. SIGNAL FAULTY. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION

Condition

The central electronic module (CEM) communicates with the left-hand seat heating module (SHM).

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) receives information from the left-hand seat heating module (SHM) registering a fault in the heater pad.

The voltage in the central electronic module (CEM) must exceed 10.5 V for at least 1.5 seconds in order for the diagnostic trouble code (DTC) to be detected.

The diagnostic trouble code (DTC) can be diagnosed at key position II.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

CEM-5F4F: START ATTEMPT. TOO MANY UNSUCCESSFUL ATTEMPTS (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-5F4F

Condition

Fig. 38: Identifying Parking Heater
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) checks the function and status parking heater.

During activation, the heater tries to start. If the heater does not start, it will try again a few times.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) receives a signal from the heater indicating that it has tried to start but failed.

The diagnostic trouble code (DTC) can be diagnosed when the heater is activated.

Substitute Value

- The heater is not activated.

Possible Source

- Fault in the fuel supply to the parking heater
- Flame sensor clogged with soot
- Blocked combustion air intake
- Contact resistance in the control module connectors
- Open-circuit or short-circuit to supply voltage in the control signal cable for the flame sensor
- Flame sensor not functioning.
- Fault in the power supply for the parking heater

Fault symptom[s]

- Poor heating in the passenger compartment.
- Parking heater/Does not work

TOO-MANY: UNSUCCESSFUL ATTEMPTS

CHECKING THE QUANTITY OF FUEL AND VOLTAGE

Fig. 39: Identifying Ignition ON
Courtesy of VOLVO CARS CORPORATION

- **HINT: A transparent hose can be used to check if fuel supply to the parking heater works.**

  If the quantity of fuel in the fuel tank is below 6 liters the heater is not permitted to start. If the battery voltage is poor the heater is not permitted to start. The combustion preheater module (CPM) interprets 3 or more failed start attempts as a fault in the heater. The heater cannot then be started until the diagnostic trouble codes (DTCs) have been erased

- Ignition on.

  NOTE: The heater must be switched off when reading off

  Read off the values.

The fuel level status must be OK and the voltage to the heater must be normal.

CHECKING FOR A SHORT CIRCUIT

Check the resistance between the fuse holder secondary side (left) and ground.

The ohmmeter should display infinite resistance.

NOTE: If the value is correct the fault could be intermittent.

Switch to trouble-shooting intermittent short circuits to ground as described in, see **SHORT-CIRCUIT TO GROUND, INTERMITTENT FAULTS** .

If the ohmmeter indicates a fault (short circuit), trouble-shoot the wires between the fuse and door control unit connector B7 for a short circuit to ground as described in, see **SHORT-CIRCUIT TO GROUND, PERMANENT FAULTS** .

The fault should be between the fuse and the common junction point 53/427.

Replace fuse.

CHECKING THE WIRING AND SWITCHES

Check the switches at the central electronic module and lock unit. Check for contact resistance and oxidation.

Check the signal cable for the lock position sensor between the central electronic module connector terminal #B13 and lock unit connector terminal #5. Check for an open-circuit.

Check the signal cable for the lock position sensor between the central electronic module connector terminal #B13 and lock unit connector terminal #5. Check for a short-circuit to supply voltage.

NOTE: **Diagnostic trouble code (DTC) REM-6A01 or REM-6A03 may also be stored if this fault occurs. Use the VCT2000 (or appropriate scan) tool to read diagnostic trouble codes (DTCs).**

  Refer to **CHECKING FOR A SHORT CIRCUIT**

CHECKING FOR AN OPEN CIRCUIT

Check door control unit connector B7 for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Trouble-shoot the wire between fuse holder secondary side (left) and door control unit connector B7 for an open circuit as described in, see **OPEN-CIRCUIT, PERMANENT FAULTS** .

If a fault is detected, check in particular the intermediate connector in the cable harness (1/control unit) for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

If there is an open circuit the fault should be between the fuse and the common junction point 53/427.

Fig. 164: Identifying Ohm Meter

CHECKING FOR A SHORT CIRCUIT

Check the resistance between the fuse holder secondary side (left) and ground.

The ohmmeter should display infinite resistance.

NOTE: If the value is correct the fault could be intermittent.

Switch to trouble-shooting intermittent short circuits to ground as described in, see **SHORT-CIRCUIT TO GROUND, INTERMITTENT FAULTS** .

If the ohmmeter indicates a fault (short circuit), trouble-shoot the wires between the fuse and door control unit connector B7 for a short circuit to ground as described in, see **SHORT-CIRCUIT TO GROUND, PERMANENT FAULTS** .

The fault should be between the fuse and the common junction point 53/427.

Replace fuse.

CHECKING FOR A SHORT CIRCUIT

Check the resistance between the fuse holder secondary side (left) and ground.

The ohmmeter should display infinite resistance.

If the value is correct, replace the fuse.

If the value deviates, trouble-shoot all the relay circuits involved for a short circuit to ground as described in, see **SHORT-CIRCUIT TO GROUND, PERMANENT FAULTS** .

HINT: Replace fuse.

HINT: If the fuse works straight away the fault is a short circuit on the relay supply wire.

HINT: If the fuse works when activating each relay the short circuit is on the component supply wire

HINT: The relay circuits involved belong to relays 2/111, 2/112, 2/113, 2/114, 2/115, 2/56, 2/59 and 2/67.

Is there a fault?

- **YES**

  OKAY: Troubleshooting has been completed.

- **NO**

  Refer to **CHECKING THE RELAY SUPPLY**

CHECKING THE RELAY SUPPLY

Remove the locking relay (2/113).

Measure the voltage between 5 in the relay socket and ground.

The voltmeter should display battery voltage.

HINT: If the value is OK but the fault still remains, connect the contacts to the lock module and link between 3 and 5 in the relay socket to force-feed the lock motor while continuing to test.

CHECKING FOR A SHORT CIRCUIT

Check the resistance between the fuse holder secondary side (left) and ground.

The ohmmeter should display infinite resistance.

If the value is correct, replace the fuse.

If the value deviates, trouble-shoot all the relay circuits involved for a short circuit to ground as described in, see **SHORT-CIRCUIT TO GROUND, PERMANENT FAULTS** .

NOTE: If the value is correct the fault could be intermittent.

HINT: Replace fuse.

HINT: If the fuse works straight away the fault is a short circuit on the relay supply wire.

HINT: If the fuse works when activating each relay the short circuit is on the component supply wire

HINT: The relay circuits involved belong to relays 2/111, 2/112, 2/113, 2/114, 2/115, 2/56, 2/59 and 2/67.

Additional information

INFORMATION

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

CEM-6A02: REAR RIGHT DOOR UNLOCKED. SIGNAL TOO HIGH. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE INFORMATION

Condition

If the central electronic module (CEM) detects a high signal from the lock position sensor 15 seconds after locking, diagnostic trouble code CEM-6A02 is displayed

Possible Source

- The lock has stuck in unlocked position
- Open circuit in lock sensor signal wire
- Lock position sensor signal wire short circuited to voltage supply
- Relay fault
- Open circuit on relay supply/defective fuse
- Fault in locking motor circuit
- Fault in rear electronic module (REM).

Fault symptom[s]

- A door does not lock / open.

SIGNAL TOO HIGH. INTERMITTENT FAULT

CHECKING THE COMPONENT

Check that the lock has not stuck by using the lock button on the inside of the door. Check that the lock unit is correctly installed.

Was a fault detected?

- **YES**

  OKAY: Troubleshooting has been completed.

- **NO**

  Refer to **CHECKING THE WIRING AND SWITCHES**

CHECKING THE WIRING AND SWITCHES

Check the switches at the central electronic module and lock unit. Check for contact resistance and oxidation.

Check the signal cable for the lock position sensor between the central electronic module connector terminal #C3 and lock module connector terminal #5. Check for an open-circuit.

Check the signal cable for the lock position sensor between the central electronic module connector terminal

#C3 and lock unit connector terminal #5. Check for an intermittent short-circuit to supply voltage.

NOTE: **Diagnostic trouble code (DTC) REM-6A09 or REM-6A0B may also be stored if this fault occurs. Use the VCT2000 (or appropriate scan) tool to read diagnostic trouble codes (DTCs).**

CHECKING FOR A SHORT CIRCUIT

Check the resistance between the fuse holder secondary side (left) and ground.

The ohmmeter should display infinite resistance.

NOTE: If the value is correct the fault could be intermittent.

Switch to trouble-shooting intermittent short circuits to ground as described in, see **SHORT-CIRCUIT TO GROUND, INTERMITTENT FAULTS** .

If the ohmmeter indicates a fault (short circuit), trouble-shoot the wires between the fuse and door control unit connector B7 for a short circuit to ground as described in, see **SHORT-CIRCUIT TO GROUND, PERMANENT FAULTS** .

The fault should be between the fuse and the common junction point 53/427.

Replace fuse.

CHECKING THE REAR RIGHT DOOR

CHECK

Is the lock to the other rear door not working?

- **YES**

  Refer to **CHECKING THE FUSE**

- **NO**

  Refer to **REPLACING THE COMPONENT**

REPLACING THE COMPONENT

Replace the relays for locking (2/113) and unlocking (2/114) in the cargo compartment relay/fuse box. At the same time check relay socket contacts for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Additional information

- To access relay/fuse box in the cargo compartment:

Is there a fault?

- **YES**

  OKAY: Troubleshooting has been completed.

- **NO**

  Refer to **CIRCUIT TEST**

CIRCUIT TEST

The fault is caused by an open circuit in one of the relay circuits or in the lock unit. To find out which circuit

contains the fault:

Disconnect the lock unit connector.

Check the contacts for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Check resistance between 4 and 6 on cable connector.

Additional information

- To access/replace the lock unit, see **LOCK MECHANISM REAR SIDE DOOR, REPLACING** .

The ohmmeter should display 0 ohm.

- **OK**

  Refer to **CHECKING THE COMPONENTS**

- **NOT OK**

  Refer to **CIRCUIT TEST, CONTINUED**

CIRCUIT TEST, CONTINUED

Check the resistance between 4 and ground and between 6 and ground on the cable connector.

The ohmmeter should display 0 ohm.

1. The ohmmeter shows a fault between 4 and ground

   Refer to **CHECKING THE UNLOCKING RELAY CIRCUIT**

2. The ohmmeter shows a fault between 6 and ground.

   Refer to **CHECKING THE LOCKING RELAY CIRCUIT**

CHECKING THE LOCKING RELAY CIRCUIT

Remove the locking relay (2/113).

Check the wire between 4 in the cable connector and 3 in the relay socket for an open circuit as described in, see **OPEN-CIRCUIT, PERMANENT FAULTS** .

If a fault is detected, check in particular the intermediate connector in the cable harness (2) for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Do the necessary corrective action.

If no fault is found, check the resistance between 4 in the relay socket and ground.

The ohmmeter should display 0 ohm.

If the resistance deviates, replace the rear electronic module (REM).

Additional information

- To access/replace the rear electronic module (REM):
  - For -2004, see: **RELAY/FUSE BOX CARGO COMPARTMENT/REAR ELECTRONIC MODULE (REM), REPLACING**

CHECKING THE UNLOCKING RELAY CIRCUIT

Remove the unlocking relay (2/114).

Check the wire between 6 in the cable connector and 3 in the relay socket for an open circuit as described in, see **OPEN-CIRCUIT, PERMANENT FAULTS** .

If a fault is detected, check in particular the intermediate connector in the cable harness (2) for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Do the necessary corrective action.

If no fault is found, check the resistance between 4 in the relay socket and ground.

The ohmmeter should display 0 ohm.

If the resistance deviates, replace the rear electronic module (REM).

CHECKING THE COMPONENTS

Check the resistance between pin 4 and 6 in the lock unit chassis contact.

The ohmmeter should display 5 ohm.

If the resistance deviates, replace the lock unit.

Additional information

- To access the rear electronic module (REM):
  - For -2004, see: **RELAY/FUSE BOX CARGO COMPARTMENT/REAR ELECTRONIC MODULE (REM), REPLACING**

Is there a fault?

- **YES**

  OKAY: Troubleshooting has been completed.

- **NO**

  Refer to **CHECKING THE RELAY SUPPLY**

CHECKING THE RELAY SUPPLY

Remove the locking relay (2/113).

Measure the voltage between 5 in the relay socket and ground.

The voltmeter should display battery voltage.

HINT: If the value is OK but the fault still remains, connect the contacts to the lock module and link between 3 and 5 in the relay socket to force-feed the lock motor while continuing to test.

CHECKING FOR A SHORT CIRCUIT

Check the resistance between the fuse holder secondary side (left) and ground.

The ohmmeter should display infinite resistance.

If the value is correct, replace the fuse.

If the value deviates, trouble-shoot all the relay circuits involved for a short circuit to ground as described in, see **SHORT-CIRCUIT TO GROUND, PERMANENT FAULTS** .

NOTE: If the value is correct the fault could be intermittent.

HINT: Replace fuse.

HINT: If the fuse works straight away the fault is a short circuit on the relay supply wire.

CHECKING THE COMPONENT

Check that the lock has not stuck by using the lock button on the inside of the door. Check that the lock unit is correctly installed.

Was a fault detected?

- **YES**

  Refer to **VERIFICATION**

- **NO**

  Refer to **CHECKING THE WIRING AND SWITCHES**

CHECKING THE WIRING AND SWITCHES

Check the switches at the central electronic module and lock unit. Check for contact resistance and oxidation.

Check the signal cable for the lock position sensor between the central electronic module connector terminal #C3 and lock unit connector terminal #5. Check for an open-circuit.

Check the signal cable for the lock position sensor between the central electronic module connector terminal #C3 and lock unit connector terminal #5. Check for a short-circuit to supply voltage.

NOTE: **Diagnostic trouble code (DTC) REM-6A09 or REM-6A0B may also be stored if this fault occurs. Use the VCT2000 (or appropriate scan) tool to read diagnostic trouble codes (DTCs).**

Is there a fault?

- **YES**

  OKAY: Troubleshooting has been completed.

- **NO**

  Refer to **CHECKING THE RELAY SUPPLY**

CHECKING THE RELAY SUPPLY

Remove the locking relay (2/111).

Measure the voltage between 5 in the relay socket and ground.

The voltmeter should display battery voltage.

HINT: If the value is OK but the fault still remains, connect the contacts to the lock module and link between 3 and 5 in the relay socket to force-feed the lock motor while continuing to test.

CHECKING FOR A SHORT CIRCUIT

Check the resistance between the fuse holder secondary side (left) and ground.

The ohmmeter should display infinite resistance.

If the value is correct, replace the fuse.

If the value deviates, trouble-shoot all the relay circuits involved for a short circuit to ground as described in, see **SHORT-CIRCUIT TO GROUND, PERMANENT FAULTS** .

HINT: Replace fuse.

HINT: If the fuse works straight away the fault is a short circuit on the relay supply wire.

HINT: If the fuse works when activating each relay the short circuit is on the component supply wire

HINT: The relay circuits involved belong to relays 2/111, 2/112, 2/113, 2/114, 2/115, 2/56, 2/59 and 2/67.

CHECK

Is the lock to the other rear door not working?

- **YES**

  Refer to **CHECKING THE FUSE**

- **NO**

  Refer to **REPLACING THE COMPONENT**

REPLACING THE COMPONENT

Replace the relays for locking (2/113) and unlocking (2/114) in the cargo compartment relay/fuse box. At the same time check relay socket contacts for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Additional information

- To access relay/fuse box in the cargo compartment:

Is there a fault?

- **YES**

  OKAY: Troubleshooting has been completed.

- **NO**

  Refer to **CIRCUIT TEST**

CIRCUIT TEST

The fault is caused by an open circuit in one of the relay circuits or in the lock unit. To find out which circuit

contains the fault:

Disconnect the lock unit connector.

Check the contacts for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Check resistance between 4 and 6 on cable connector.

- **OK**

  Refer to **CHECKING THE COMPONENTS**

- **NOT OK**

  Refer to **CIRCUIT TEST, CONTINUED**

CIRCUIT TEST, CONTINUED

Check the resistance between 4 and ground and between 6 and ground on the cable connector.

The ohmmeter should display 0 ohm.

1. The ohmmeter shows a fault between 4 and ground

   Refer to **CHECKING THE UNLOCKING RELAY CIRCUIT**

2. The ohmmeter shows a fault between 6 and ground.

   Refer to **CHECKING THE LOCKING RELAY CIRCUIT**

CHECKING THE LOCKING RELAY CIRCUIT

Remove the locking relay (2/113).

Check the wire between 4 in the cable connector and 3 in the relay socket for an open circuit as described in, see **OPEN-CIRCUIT, PERMANENT FAULTS** .

If a fault is detected, check in particular the intermediate connector in the cable harness (2) for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Do the necessary corrective action.

If no fault is found, check the resistance between 4 in the relay socket and ground.

The ohmmeter should display 0 ohm.

If the resistance deviates, replace the rear electronic module (REM).

INFORMATION

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

CEM-6A03: REAR LEFT DOOR LOCKED. SIGNAL TOO LOW. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION

Condition

Diagnostic trouble code (DTC) n CEM-6A03 is stored if the central electronic module (CEM) registers a low signal from the lock position sensor 15 seconds after unlocking.

Possible Source

- The lock has jammed in the locked position.
- Short-circuit to ground in the signal cable for the lock position sensor.
- Fault in the relay.
- Open-circuit in the relay supply / defective fuse.
- Fault in the locking motor circuit.
- Fault in the rear electronic module.

Fault symptom[s]

- Does not lock / unlock a door.

SIGNAL TOO LOW. INTERMITTENT FAULT

CHECKING THE COMPONENT

Check that the lock has not stuck by using the lock button on the inside of the door. Check that the lock unit is correctly installed.

Was a fault detected?

- **YES**

  OKAY: Troubleshooting has been completed.

- **NO**

  Refer to **CHECKING THE WIRING AND SWITCHES**

CHECKING THE WIRING AND SWITCHES

Check the signal cable for the lock position sensor between the central electronic module connector terminal #B13 and lock module connector terminal #5. Check for an open-circuit.

NOTE: **Diagnostic trouble code (DTC) REM-6A04 or REM-6A05 may also be stored if this fault occurs. Use the VCT2000 (or appropriate scan) tool to read diagnostic trouble codes (DTCs).**

CHECK

Is the lock to the other rear door not working?

- **YES**

  Refer to **CHECKING THE FUSE**

- **NO**

  Refer to **REPLACING THE COMPONENT**

REPLACING THE COMPONENT

Replace the relays for locking (2/111) and unlocking (2/112) in the cargo compartment relay/fuse box. At the same time check relay socket contacts for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Additional information

- To access relay/fuse box in the cargo compartment:

Is there a fault?

- **YES**

  OKAY: Troubleshooting has been completed.

- **NO**

  Refer to **CIRCUIT TEST**

CIRCUIT TEST

The fault is caused by an open circuit in one of the relay circuits or in the lock unit. To find out which circuit

contains the fault:

Disconnect the lock unit connector.

Check the contacts for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Check resistance between 4 and 6 on cable connector.

Additional information

- To access/replace the lock unit, see **LOCK MECHANISM REAR SIDE DOOR, REPLACING** .

- **NOT OK**

  Refer to **CIRCUIT TEST, CONTINUED**

CIRCUIT TEST, CONTINUED

Check the resistance between 4 and ground and between 6 and ground on the cable connector.

The ohmmeter should display 0 ohm.

1. The ohmmeter shows a fault between 4 and ground

   Refer to **CHECKING THE UNLOCKING RELAY CIRCUIT**

2. The ohmmeter shows a fault between 6 and ground.

   Refer to **CHECKING THE LOCKING RELAY CIRCUIT**

CHECKING THE LOCKING RELAY CIRCUIT

Remove the locking relay (2/111).

Check the wire between 4 in the cable connector and 3 in the relay socket for an open circuit as described in, see **OPEN-CIRCUIT, PERMANENT FAULTS** .

If a fault is detected, check in particular the intermediate connector in the cable harness (2) for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Do the necessary corrective action.

If no fault is found, check the resistance between 4 in the relay socket and ground.

The ohmmeter should display 0 ohm.

If the resistance deviates, replace the rear electronic module (REM).

CHECKING THE FUSE

Remove the fuse 11C/36 in cargo compartment fuse box.

Check that fuse is intact and check for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Additional information

- To access relay/fuse box in the cargo compartment:
  - For -2004, see: **RELAY/FUSE BOX CARGO COMPARTMENT/REAR ELECTRONIC MODULE (REM), REPLACING**

Is the fuse intact?

- **YES**

  Refer to **CHECKING THE VOLTAGE**

- **NO**

  Refer to **CHECKING FOR A SHORT CIRCUIT**

CHECKING FOR AN OPEN CIRCUIT

Check door control unit connector B7 for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Trouble-shoot the wire between fuse holder secondary side (left) and door control unit connector B7 for an open circuit as described in, see **OPEN-CIRCUIT, PERMANENT FAULTS** .

If a fault is detected, check in particular the intermediate connector in the cable harness (1/control unit) for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

If there is an open circuit the fault should be between the fuse and the common junction point 53/427.

Fig. 459: Identifying Ohm Meter

CHECKING FOR A SHORT CIRCUIT

Check the resistance between the fuse holder secondary side (left) and ground.

The ohmmeter should display infinite resistance.

NOTE: If the value is correct the fault could be intermittent.

Switch to trouble-shooting intermittent short circuits to ground as described in, see **SHORT-CIRCUIT TO GROUND, INTERMITTENT FAULTS** .

If the ohmmeter indicates a fault (short circuit), trouble-shoot the wires between the fuse and door control unit connector B7 for a short circuit to ground as described in, see **SHORT-CIRCUIT TO GROUND, PERMANENT FAULTS** .

The fault should be between the fuse and the common junction point 53/427.

Replace fuse.

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

ELECTRICAL

Cables And Fuses - Diagnostic Trouble Codes and Associated Procedures

CEM-8F26: WINDSHIELD WIPERS. SIGNAL TOO HIGH (2006-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-8F26

Condition

The central electronic module (CEM) checks the windshield wipers.

The diagnostic trouble code (DTC) is stored if the Central electronic module (CEM) detects too high a signal on the output for the windshield wiper low/high speed relay.

The diagnostic trouble codes (DTCs) can be diagnosed when windshield wipers are activated, full speed.

Fig. 1: Identifying Windshield Wiper Switch
Courtesy of VOLVO CARS CORPORATION

Substitute Value

- None.

Possible Source

- Short-circuit to supply voltage in the cable.

Fault symptom[s]

- Windshield wiper does not work

SIGNAL TOO HIGH

CHECKING THE CABLE

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.

Checking the cable and relay

Check the cable between the central electronic module (CEM) and the windshield wiper relay low/high speed (2/90). Check for a short-circuit to supply voltage.

Take readings between:

- Central electronic module (CEM) #C3(#3) and relay, windshield wipers low/high speed (2/90) #2.

If no fault is found in the signal cable try replacing relay 2/90.

Remedy as necessary.

CEM-8F26: WINDSHIELD WIPER, HIGH SPEED RELAY. SIGNAL TOO HIGH. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE INFORMATION

Condition

Relay must be activated to detect the diagnostic trouble code. If the control unit detects that the relay, wiper high speed, is short circuited to voltage supply, diagnostic trouble code CEM 8F26 is displayed.

Substitute Value

None.

Possible Source

- Short circuit to voltage supply.

Fault symptom[s]

- Wiper only works on lowest speed.

SIGNAL TOO HIGH. INTERMITTENT FAULT

CHECKING THE RELAY

Check that the relay is securely connected and not defective. Check for contact resistance and oxidation. Check for loose connections.

The following applies only in the event of an open-circuit in the cable:

HINT: The fault may have caused by contact resistance, oxidation or loose connections in the supply to the relay. The voltage must be 12 V at both terminals #1 and #5 for relay 2/91. For relay 2/90 the voltage

must be 12 V at terminal #1. Check fuse 11B/13 in the integrated relay/fusebox in the engine compartment in particular.

Using the table below, check the cable between the central electronic module (CEM) and the windshield wiper relay. Check for an intermittent short-circuit to supply voltage. Check for contact resistance and oxidation.

Diagnostic Trouble Code (DTC)	Control module	Relay
CEM-8F23	#13A	#2 (2/91)
CEM-8F26	#14A	#2 (2/90)

Also check the connector. Check for contact resistance and oxidation. Check for an intermittent short-circuit to supply voltage.

CHECKING THE RELAY AND SUPPLY

Check that relay 2/90 is correctly connected. Check that the relay is not defective.

HINT: This tip applies only in the event of an open-circuit in cable.

HINT: The fault may have been caused by an open-circuit in the supply to the relay. The voltage must be 12 V at terminal #1 for relay 2/90. Check fuse 11B/13 in particular.

CEM-8F28: WINDSHIELD WIPER, HIGH SPEED RELAY. SIGNAL MISSING. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE INFORMATION

Condition

Relay should not have to be activated to display the diagnostic trouble code. If the central electronic module (CEM) detects an open circuit on the wiper high speed relay, diagnostic trouble code CEM-8F28 is displayed.

Substitute Value

None.

Possible Source

- Open circuit in signal wire
- Open circuit in power supply to the relay
- Faulty relay
- Relay is not installed.

Fault symptom[s]

- Wiper only works on lowest speed

FAULTY SIGNAL OR SIGNAL MISSING. INTERMITTENT FAULT

CHECKING THE RELAY

Check that the relay is securely connected. Check for contact resistance and oxidation. Check for loose connections.

The following applies only in the event of an open-circuit in the cable:

HINT: The fault may have caused by contact resistance, oxidation or loose connections in the supply to the relay. The voltage must be 12 V at both terminals #1 and #5 for relay 2/91. For relay 2/90 the voltage must be 12 V at terminal #1. Check fuse 11B/13 in the integrated relay/fusebox in the engine compartment in particular.

Using the table below, check the cable between the central electronic module (CEM) and the windshield wiper relay. Check for contact resistance and oxidation. Check for loose connections.

Diagnostic Trouble Code (DTC)	Control module	Relay
CEM-8F25	#13A	#2 (2/91)
CEM-8F28	#14a	#2 (2/90)

Also check the connector. Check for contact resistance and oxidation. Check for loose connections.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-8F2C

Condition

Fig. 49: Identifying Windshield Wiper Lever
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) checks the windshield wipers.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) detects that the windshield wiper is in "parking position" for longer than 5 seconds and the steering wheel module (SWM) indicates that the windshield wiper should be activated.

The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute Value

- None.

Possible Source

- Damaged windshield wiper motor
- Short-circuit to supply voltage in the power supply cable
- Open-circuit in the power supply cable.

Fault symptom[s]

- The windshield wipers are not working
- No rain sensor function.

SIGNAL TOO HIGH

CHECKING THE CABLE

HINT: The fault could also have been caused by the windshield wipers sticking.

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.

Check the cable between the central electronic module (CEM) and the windshield wiper motor (6/1). Check for a short-circuit to supply voltage. Check for an open-circuit.

Take readings between Central electronic module (CEM) terminal #C31(#31) and the windshield wiper motor (6/1) #3.

Check the cable between the central electronic module (CEM) and the rain sensor (7/149). Check for a short-circuit to supply voltage. Check for an open-circuit.

Take readings between Central electronic module (CEM) terminal #D11 (#11) and rain sensor (7/149) #4.

SIGNAL TOO LOW

CHECKING THE CABLE

HINT: The fault could also have been caused by the windshield wipers sticking.

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.

Check the cable between the central electronic module (CEM) and the windshield wiper motor (6/1). Check for a short-circuit to ground.

Take readings between Central electronic module (CEM) terminal #C31(#31) and the windshield wiper motor (6/1) #3.

Check the cable between the central electronic module (CEM) and the rain sensor (7/149). Check for a short-circuit to ground.

Take readings between Central electronic module (CEM) terminal #D11 (#11) and rain sensor (7/149) #4.

Also check the connectors.

If no other faults are found try a new windshield wiper motor (6/1).

Remedy as necessary.

CEM-8F2E: WIPERS. SIGNAL TOO LOW. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE INFORMATION

Condition

If the central electronic module (CEM) indicates that the windscreen wiper is somewhere on the windscreen for longer than 5 seconds and the steering wheel module (SWM) indicates that the windscreen wiper should be activated, diagnostic trouble code CEM 8F2E is displayed.

Substitute value

- Windshield wipers are run in low speed position for 6 seconds and then are stationary anywhere on the windshield for 6 seconds. After two repetitions the windshield wipers are stationary for one minute before the procedure is repeated.

Possible Source

- The signal line between Central electronic module (CEM) and the rain sensor is short-circuited to ground.
- The signal line between the position sensor in the wiper motor and Central electronic module (CEM) is short-circuited to ground.
- Damaged windshield wiper motor.

HINT: The signal line between Central electronic module (CEM) and the rain sensor may be trapped under the foot of the interior rearview mirror.

CEM-8F52: RELAY, HEADLAMP WASH / WIPE. SIGNAL TOO LOW OR SIGNAL MISSING (2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-8F52

Condition

The central electronic module (CEM) checks the output signal to the relay coil for relay, headlamp wash / wipe.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the output signal to the relay coil is too low/missing.

The diagnostic trouble code (DTC) can be detected when the relay driver is not activated.

Substitute Value

- None.

Possible Source

- Fuse for washer pump blown
- Short-circuit to ground/open-circuit in the signal cable
- Relay defective/missing.

Fault symptom[s]

- The headlamp washer motor does not operate.

CEM-8F52: RELAY, HEADLAMP WASH / WIPE. SIGNAL TOO LOW OR SIGNAL MISSING (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-8F52

Condition

Fig. 122: Identifying Central Electronic Module (CEM)
Courtesy of VOLVO CARS CORPORATION

The Central electronic module (CEM) checks the output signal to the relay winding for headlight cleaning.

If Central electronic module (CEM) registers that the output signal to the relay winding is missing or too low, the diagnostic trouble code is generated.

The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute Value

- None.

Possible Source

- The washer pump's fuse has failed.
- Open-circuit or short-circuit to ground in the signal cable.
- Damaged relay.
- Short-circuiting in the pump for high-pressure washing.

Fault symptom[s]

- Headlight washer pump does not work

SIGNAL TOO LOW OR SIGNAL MISSING

CHECKING FUSES

Check that the fuse for the high-pressure washer is intact. Replace the fuse if necessary.

After changing fuse, erase trouble codes.

Activate ignition position II.

Try to activate the headlight washers with the lever.

HINT: The washer must be activated for more than 0.3 seconds for the high-pressure washer to be activated. The high-pressure washer is activated every fifth time that the washers are activated if not more than 10 minutes have passed since the last activation. Warning light for low washer fluid level may not be on.

If the trouble code does not return and the high-pressure washer works, no further action is needed.

If the fuse fails again, or if the trouble code returns, continue troubleshooting.

Do you wish to continue with fault tracing?

- **YES**

  Refer to **CHECKING THE COMPONENT**

  Refer to **VERIFICATION**

CHECKING THE COMPONENT

Replace relay 2/182.

Activate high-pressure washing by activating the washer for the windshield.

HINT: The washer must be activated for more than 0.3 seconds for the high-pressure washer to be activated. The high-pressure washer is activated every fifth time that the washers are activated if not more than 10 minutes have passed since the last activation.

If the function is OK, the cause of the fault was a damaged relay (short-circuit in the relay).

Do you wish to continue with fault tracing?

CHECKING FUSEBOX

Remove headlight washer relay (2/182) from the fuse box socket.

Check the relay winding's drive circuit for short-circuiting to voltage by measuring voltage between #2 and ground in the relay socket.

Voltage between #2 and ground shall be battery voltage.

  Refer to **VERIFICATION**

CHECKING HIGH-PRESSURE WASHER PUMP

Check that the fuse for the high-pressure washer is intact.

Disconnect the pump for high-pressure washing from its connector.

Try to activate the headlight washers with the lever.

If the fuse does not fail when the washer pump is disconnected, the cause of the trouble code being set is probably an internal short circuit in the washer pump for the headlights. Try with changing high-pressure washer pump.

If the fuse fails, even if the pump is disconnected, the pump is probably okay. Continue troubleshooting.

CEM-8FD0: RELAY, AUXILIARY LAMP. SIGNAL TOO HIGH (2006-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-8FD0

Condition

The central electronic module (CEM) supplies voltage to the extra lights.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) detects too high a signal on the control signal for the auxiliary lamp relay.

The relay for the auxiliary lamp must be activated for the diagnostic trouble code (DTC) to be stored.

Substitute Value

- If the fault has been detected in 100 ignition cycles, the output is closed permanently until the diagnostic trouble code is erased (applies from structure week 200539).

Possible Source

- Short-circuit to battery voltage in the signal cable to the auxiliary lamps relay.

Fault symptom[s]

- Auxiliary lights do not function

SIGNAL TOO HIGH

CHECKING THE CABLE

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.

Checking the cable and relay

Check the cable between the central electronic module (CEM) and the auxiliary lamps relay (2/64). Check for a short-circuit to supply voltage.

Take readings between:

- Central electronic module (CEM) #C9 (#9) and relay, auxiliary lamps, (2/64) #1.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-9F20

Condition

Fig. 168: Identifying Twilight Sensor
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) receives information about the prevailing light conditions from the twilight sensor. This information is used to determine the light intensity for symbols and the instrument lighting. Two different levels are pre-defined, one for day and one for night. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers a short-circuit to battery voltage in the twilight sensor circuit.

The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.

Substitute Value

- Light intensity for night is used.

Possible Source

- Short-circuit to supply voltage in the signal cable
- Damaged twilight sensor.

Fault symptom[s]

CEM-DD00: COMMUNICATION WITH LSM CONTROL MODULE AND CPM CONTROL MODULE. COMMUNICATION FAULT (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-DD00

Condition

Fig. 196: Identifying Light Switch Module (LSM)
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) sends and receives information via a standardized serial communication system. This system is called Volcano Lite (VOLvo CAN based distributed real time Operative environment). The diagnostic trouble code (DTC) is stored if the control module registers serious interference such as blocked communication with the light switch module (LSM) or combustion preheater module (CPM).

The diagnostic trouble code (DTC) can be diagnosed when the ignition key is in position II for at least 10 seconds and with the battery voltage above 10.5 V.

NOTE: **In the event of CEM-DDxx diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors. The central electronic module (CEM) is the only control module that monitors the voltage level in the signal cables. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of this type of fault unless VIDA (Volvo scan tool) has indicated that the central electronic module (CEM) has an internal fault.**

Substitute Value

- None.

Possible Source

- Short-circuit to supply voltage in the signal cable
- Short-circuit to ground in the signal cable
- Internal fault in another control module in the same part of the network.

Fault symptom[s]

- The light switch does not operate
- Beam height control does not function

- Ignition off
- Disconnect connectors D and C from the central electronic module (CEM).

  The diagnostic trouble code (DTC) indicates that the communication between the light switch module (LSM), central electronic module (CEM) and combustion preheater module (CPM) is not working. This may be due to a fault in the signal cable between the control modules or a damaged communication device in one or all of the control modules.

  Check the signal cable. Check for a short-circuit to ground.

  Take readings between:

  - Central electronic module (CEM) terminal #D41 (#41) and light switch module (LSM) terminal #3

- Central electronic module (CEM) terminal #C32 (#32) and combustion preheater module (CPM) terminal #6.

The diagnostic trouble code indicates that communication between the central electronic module (CEM) and the alternator control module (ACM) (not vehicles with a V8 engine), the left camera module (LCM) (optional extra) and the right camera module (RCM) (optional extra) is inoperative. This could be due to a fault in the signal lead between the control modules or a damaged communication unit in one or all of the control modules.

NOTE: **All vehicles from and including model year 2005 are equipped with a signal cable to the Left Camera Module (LCM) / Right Camera Module (RCM) even if the vehicle is not equipped with BLIS system. This means that measurements must always be carried out up to the 12-pin connector in the external doors when the diagnostic trouble code (DTC) has been detected on LIN bus 2.**

Check the signal lead between the central electronic module (CEM) and the alternator control module (ACM) for an open circuit or shorting to ground.

CHECKING THE COMPONENT

For vehicles equipped with the Blind Spot Indication System (BLIS)

The LEDs should flash three times whenever the Blind Spot Indication System (BLIS) is activated.

Switch on the ignition to check the right and left sides.

If any LED fails to flash three times on activation, try changing the control module on that side.

If both LEDs flash three times on activation, try changing the alternator control module (ACM).

For vehicles without the Blind Spot Indication System (BLIS)

Try changing the alternator control module (ACM).

Select the desired alternative:

1. Change the alternator control module (ACM).

   Refer to **REPLACING THE CONTROL MODULE**

2. Change the left camera module (LCM) / right camera module (RCM).

   Refer to **REPLACING THE CONTROL MODULE**

REPLACING THE CONTROL MODULE

CEM-DD30: COMMUNICATION WITH THE ALTERNATOR CONTROL MODULE (ACM). SIGNAL MISSING (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-DD30

Condition

Fig. 245: Identifying Generator (GEN)
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) transmits and receives information via a standardized serial communication method - LIN (Local Interconnect Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference such as blocked LIN communication with the alternator control module (ACM).

The diagnostic trouble code (DTC) can be detected when the ignition key is in position II for at least 10 seconds and the battery voltage exceeds 10.5 V.

NOTE: **In the event of CEM-DDxx diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the LIN network. The central electronic module (CEM) is the only control module that monitors the voltage level in the LIN wiring. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a LIN fault unless VIDA (Volvo scan tool) has indicated that the central electronic module (CEM) has an internal fault.**

Substitute Value

Possible Source

- Short-circuit between the LIN wiring
- Open-circuit in the LIN wiring
- Internal fault in another control module in the same part of the LIN network.

Fault symptom[s]

CEM-DD51: COMMUNICATION WITH THE STEERING WHEEL MODULE (SWM). SIGNAL MISSING (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-DD51

Condition

Fig. 283: Identifying Steering Wheel Control Module
Courtesy of VOLVO CARS CORPORATION

The Central Electronic Module (CEM) both transmits and receives information via a standardized serial

communication method - LIN (Local Interconnect Network). If the control module registers serious interference, for example that the LIN communication to the cruise control switch is blocked, then the Diagnostic Trouble Code (DTC) is generated.

The diagnostic trouble code (DTC) can be detected when the ignition key is in position II for at least 10 seconds and the battery voltage exceeds 10.5 V.

NOTE: **In the event of CEM-DDxx diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the LIN network. The central electronic module (CEM) is the only control module that monitors the voltage level in the LIN wiring. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a LIN fault unless VADIS fault-tracing has indicated that the central electronic module (CEM) has an internal fault.**

Substitute Value

- None.

Possible Source

- Short-circuit between the LIN wiring
- Open-circuit in the LIN wiring
- Internal fault in another control module in the same part of the LIN network.

CEM-DF01: CAN-H, LOW SPEED NETWORK. SIGNAL MISSING (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-DF01

Condition

Fig. 295: Identifying Central Electronic Module
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) checks the voltage in the CAN wiring in the low speed network. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers an open-circuit in CAN

H or CAN L in the low speed network.

NOTE: **The central electronic module (CEM) is the only control module that monitors the voltage level in the Control area network wiring. The central electronic module (CEM) is the only control module that can directly store diagnostic trouble codes (DTCs) for an open-circuit in these conductors. However other control modules can store diagnostic trouble codes (DTCs) as a result of the open-circuit. Do not replace the central electronic module (CEM) in the event of a CAN fault unless VIDA (Volvo scan tool) has indicated that the central electronic module (CEM) has an internal fault.**

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Substitute Value

Possible Source

- Open-circuit in one of the control area network (CAN) cables on the low speed network
- Contact resistance in the terminals.

- Radio interference.

SIGNAL TOO HIGH. INTERMITTENT FAULT.

CHECKING CONNECTORS AND BUS WIRE

NOTE: Remember that the CAN network is only a communications network. There are therefore no fuses, switches or sensors on the CAN bus. Check the resistance as described below (see reference).

NOTE: To maintain the correct values the battery should be disconnected before measuring resistance.

Check the bus wire for a short circuit to voltage supply as described in, see **SHORT-CIRCUIT TO SUPPLY VOLTAGE, INTERMITTENT FAULTS** , and for an intermittent open circuit as described in **OPEN-CIRCUIT, INTERMITTENT FAULTS** .

HINT: When checking for an open circuit, check if possible from the rear of the connector concerned so that it is not damaged.

Also check the intermediate connectors for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** , and for a loose contact as described in **LOOSE CONNECTIONS (TERMINALS)** .

HINT: If the fault is found before all the wires below have been checked, the remaining trouble-shooting should not be done.

The following wires and connectors should be checked to locate the short circuit.

Do not replace the central electronic module (CEM) in the event of a CAN fault unless VIDA (Volvo scan tool) has indicated that the central electronic module (CEM) has an internal fault.**

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Substitute Value

- None.

Possible Source

- Short-circuit to ground in the low speed network.

Fault symptom[s]

- Radio interference.

CEM-DF04: CAN-L, LOW-SPEED NETWORK. SIGNAL TOO LOW. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-DF04

Condition

Diagnostic trouble codes (DTCs) are stored if the central electronic module (CEM) registers that there is a short-circuit to ground in the CAN L in the low speed network.

NOTE: **In the event of DFxx diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replace as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the Control area network The central electronic module (CEM) is the only control module that monitors the voltage level in the Control area network wiring. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a CAN fault unless VIDA (Volvo scan tool) has indicated that the central electronic module (CEM) has an internal fault.**

Substitute Value

None.

Possible Source

- Short-circuit to ground in the low speed network.

Fault symptom[s]

- The central locking system does not function at all
- Radio interference.

SIGNAL TOO LOW. INTERMITTENT FAULT.

CHECKING CONNECTORS AND BUS WIRE

NOTE: **Remember that the CAN network is only a communications network. There are therefore no fuses, switches and sensors on the CAN bus. Check the resistance as described below (see reference).**

NOTE: **To maintain the correct values the battery should be disconnected when measuring resistance.**

Check the bus wire for a short circuit to ground as described in, see **SHORT-CIRCUIT TO GROUND, INTERMITTENT FAULTS** .

Also check the intermediate connectors for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** and for a loose contact as described in **LOOSE CONNECTIONS (TERMINALS)** .

HINT: If the fault is found before all the wires below have been checked trouble-shooting is not necessary on the wires.

The following wires and connectors should be checked to locate the short circuit.

Wire between:

CEM-6A04: REAR RIGHT DOOR LOCKED. SIGNAL TOO LOW. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE INFORMATION

Condition

If the central electronic module (CEM) detects a low signal from the lock position sensor 15 seconds after unlocking, diagnostic trouble code CEM-6A04 is displayed.

Possible Source

- The lock has stuck in locked position
- Lock position sensor signal wire short circuited to ground
- Relay fault
- Open circuit on relay supply/defective fuse
- Fault in locking motor circuit
- Fault in rear electronic module (REM).

Fault symptom[s]

- A door does not lock / open.

SIGNAL TOO LOW. INTERMITTENT FAULT

CHECKING THE COMPONENT

Check that the lock has not stuck by using the lock button on the inside of the door. Check that the lock unit is correctly installed.

Was a fault detected?

- **YES**

  OKAY: Troubleshooting has been completed.

- **NO**

  Refer to **CHECKING THE WIRING AND SWITCHES**

CHECKING THE WIRING AND SWITCHES

Check the signal cable for the lock position sensor between the central electronic module connector terminal #C3 and lock unit connector terminal #5. Check for an open-circuit.

NOTE: **Diagnostic trouble code (DTC) REM-6A0C or REM-6A0E may also be stored if this fault occurs. Use the VCT2000 (or appropriate scan tool) to read diagnostic trouble codes (DTCs).**

CHECKING THE REAR LEFT DOOR

CHECK

Is the lock to the other rear door not working?

- **YES**

  Refer to **CHECKING THE FUSE**

- **NO**

  Refer to **REPLACING THE COMPONENT**

REPLACING THE COMPONENT

Replace the relays for locking (2/111) and unlocking (2/112) in the cargo compartment relay/fuse box. At the same time check relay socket contacts for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Additional information

- To access relay/fuse box in the cargo compartment:

Is there a fault?

- **YES**

  OKAY: Troubleshooting has been completed.

- **NO**

  Refer to **CIRCUIT TEST**

CIRCUIT TEST

The fault is caused by an open circuit in one of the relay circuits or in the lock unit. To find out which circuit

contains the fault:

Disconnect the lock unit connector.

Check the contacts for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Check resistance between 4 and 6 on cable connector.

Additional information

- To access/replace the lock unit, see **LOCK MECHANISM REAR SIDE DOOR, REPLACING** .

- **NOT OK**

  Refer to **CIRCUIT TEST, CONTINUED**

CIRCUIT TEST, CONTINUED

Check the resistance between 4 and ground and between 6 and ground on the cable connector.

The ohmmeter should display 0 ohm.

1. The ohmmeter shows a fault between 4 and ground

   Refer to **CHECKING THE UNLOCKING RELAY CIRCUIT**

2. The ohmmeter shows a fault between 6 and ground.

   Refer to **CHECKING THE LOCKING RELAY CIRCUIT**

CHECKING THE LOCKING RELAY CIRCUIT

Remove the locking relay (2/111).

Check the wire between 4 in the cable connector and 3 in the relay socket for an open circuit as described in, see **OPEN-CIRCUIT, PERMANENT FAULTS** .

If a fault is detected, check in particular the intermediate connector in the cable harness (2) for contact resistance and oxidation as described in, see **CONTACT RESISTANCE AND OXIDATION** .

Do the necessary corrective action.

If no fault is found, check the resistance between 4 in the relay socket and ground.

The ohmmeter should display 0 ohm.

If the resistance deviates, replace the rear electronic module (REM).

CHECKING FOR A SHORT CIRCUIT

Check the resistance between the fuse holder secondary side (left) and ground.

The ohmmeter should display infinite resistance.

If the value is correct, replace the fuse.

If the value deviates, trouble-shoot all the relay circuits involved for a short circuit to ground as described in, see **SHORT-CIRCUIT TO GROUND, PERMANENT FAULTS** .

HINT: Replace fuse.

HINT: If the fuse works straight away the fault is a short circuit on the relay supply wire.

HINT: If the fuse works when activating each relay the short circuit is on the component supply wire

HINT: The relay circuits involved belong to relays 2/111, 2/112, 2/113, 2/114, 2/115, 2/56, 2/59 and 2/67.

CHECKING FOR A SHORT CIRCUIT

Check the resistance between the fuse holder secondary side (left) and ground.

The ohmmeter should display infinite resistance.

NOTE: If the value is correct the fault could be intermittent.

Switch to trouble-shooting intermittent short circuits to ground as described in, see **SHORT-CIRCUIT TO GROUND, INTERMITTENT FAULTS** .

If the ohmmeter indicates a fault (short circuit), trouble-shoot the wires between the fuse and door control unit connector B7 for a short circuit to ground as described in, see **SHORT-CIRCUIT TO GROUND, PERMANENT FAULTS** .

The fault should be between the fuse and the common junction point 53/427.

Replace fuse.

COMMUNICATION FAULT

REPLACING THE ANTENNA UNIT

The antenna unit has registered an internal fault.

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the antenna module (ATM) or can be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. If the fault recurs, replace the antenna unit.

HINT: The diagnostic trouble code (DTC) can also be stored by temporary interference in the communication with the antenna unit. If this is the case the antenna unit need not be replaced and the diagnostic trouble code (DTC) can be erased.

With the ignition on the central electronic module (CEM) reads the transponder signal. The diagnostic trouble code (DTC) is stored if the transponder responds with an unknown transponder, a non-approved code (not stored in the memory), no transponder code at all or an unknown communication format.

NOTE: **This diagnostic trouble code (DTC) may be stored for example if there are several ignition keys on the same key ring and one of them is inserted in the ignition switch.**

Substitute Value

- None.

Possible Source

- The ignition key has a damaged transponder
- The ignition key is of the wrong type. It has no transponder
- The ignition key has previously belonged to the vehicle but has been erased from the memory for the central electronic module (CEM)
- The ignition key is a new key and has not yet been programmed into the memory for the central electronic module (CEM)
- Several keys are too close to each other during the read off
- An electronic door key was too close to the antenna unit during the read off
- An automatic road toll transponder is installed too close to the antenna unit
- EMC interference (strong electrical field) during the communication phase (when starting the engine)
- The ignition key is a Volvo key but for a different model
- The ignition key belongs to another Volvo of the same type, i. e. it has a different transponder code
- The ignition key is for another make of car and therefore does not have the same type of transponder.

CEM-6C48: TRANSPONDER TYPE. FAULTY SIGNAL. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE INFORMATION

Condition

When the ignition is on, the central electronic module (CEM) takes a transponder reading. If the transponder responds with an unrecognized transponder code that is not approved (i. e. not stored in the memory), no transponder code or in an unrecognized communication form, the diagnostic trouble code (DTC) is generated.

NOTE: This diagnostic trouble code can be generated if, for example, several ignition keys hang together on the same keychain when one of them is inserted in the ignition switch.

Substitute Value

Nothing.

Possible Source

- The ignition key has a damaged transponder.
- The ignition key is faulty, or has no transponder
- The ignition key is a constituent of the vehicle, that is to say it has the correct security code programmed into the transponder memory, but the key's transponder code is not programmed as it has been cleared from the memory of the central electronic module (CEM).
- The ignition key is new and its transponder code has not yet been programmed into the memory of the central electronic module (CEM).
- Several similar keys are used to ensure that several transponder codes have been read during transponder reading. The result is an unknown code which is a combination of several keys' transponder codes

CHECKING THE KEY TYPE

NOTE: **Check to, see if there are several keys (with transponders) on the same key ring. These keys should be separate so that they do not touch the key being used. Also check that no other transponder, such as an electronic door key or an identity card with an integrated transponder, is near by.**

If there is an automatic toll road transponder in the car, this should be positioned as far from the antenna unit as possible.

Visually check to, see if the key in the ignition switch is the correct type. See the illustration.

Check that the color marking (a small semi-circular plastic marking positioned on the head of the key nearest one of the short sides of the metal section) is the correct color: The correct color is gray or red.

The key is for another type of Volvo if the color marking is black or blue.

If the color is not correct, replace the key with the color marking as above. Insert the key in the ignition switch. If the key with the correct color marking is missing order a new key. Program the key(s). See **ADD/REMOVE KEY** .

Refer to **CHECKING START**

CHECKING START

Use the same key which previously could not start the engine. Carry out three more start attempts.

Note, if the start attempts are carried out in quick succession, remove the key from the ignition switch for at least two seconds between each start attempt. Otherwise a new transponder check will not be carried out. (If the key is left in the ignition switch between each start attempt, a new transponder check will not occur until the ignition has been switched off for approximately 30 seconds.)

One of the following may occur:

1. The engine starts every time

   Refer to **COMMUNICATION**

2. The engine starts at least once

   Refer to **DAMAGED TRANSPONDER**

3. The engine does not start.

   Refer to **INCORRECT KEY**

COMMUNICATION

HINT: The fault was due to a temporary disruption in communication between the transponder and the central electronic module (CEM).

  Refer to **VERIFICATION**

INCORRECT KEY

The key is for another vehicle. The transponder code and the mechanical key code (key fits in the ignition switch) happen to match, but the security code does not match that of the vehicle in question.

Order new key(s). Program the key(s). See **ADD/REMOVE KEY** .

FAULT-TRACING INFORMATION

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

CEM-6C57: TRANSPONDER COMMUNICATION FAULTY SIGNAL (2011-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-6C57

Condition

The central electronic module (CEM) is continuously supplied with the necessary information from the phone module (PHM). The central electronic module (CEM) checks information coming from the phone module (PHM).

The diagnostic trouble code (DTC) is stored if the control module detects that:

- The transmitting control module sends an incorrect value to the central electronic module (CEM).

The control module's test for the diagnostic trouble code (DTC) starts in the event of:

- All ignition positions.

NOTE: The control module can only detect the fault once the test has been started and the diagnostic trouble code (DTC) is stored when the conditions are met.

Substitute Value

- None.

Possible Source

- Incorrect software in the phone module (PHM).
- Incorrect software in the central electronic module (CEM).

HINT: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the Control area network. Do not replace the Central electronic module (CEM) unnecessarily.

Fault symptom[s]

- Volvo On Call/Does not work
- Volvo On Call/Other Volvo On Call problems

FAULT-TRACING

CHECKING SOFTWARE

Remedy the fault by downloading new software to the Phone module (PHM).

If the fault remains, download new software in Central electronic module (CEM).

CEM-6D01: RELAY, WINDOW LIFT LR UP. SIGNAL TOO HIGH. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE INFORMATION

Condition

If the control unit registers signal too high in the relay coil (2/116) when the window lift in the rear LH door is activated upwards, diagnostic trouble code CEM-6D01 will be set.

Substitute Value

- None.

Possible Source

- Defective relay (short circuit in the relay coil) which means that the window lift cannot be operated.
- Defective control unit.

Fault symptom[s]

- Electric window lift does not work.

SIGNAL TOO HIGH. INTERMITTENT FAULT

CHECKING THE WIRING

Check the relay coil driver circuit for an intermittent short-circuit to supply voltage by taking a voltmeter reading between terminal #2 and ground in the relay base for relay 2/116.

For further information about a short-circuit to supply voltage, see **SHORT-CIRCUIT TO SUPPLY VOLTAGE, INTERMITTENT FAULTS** .

HINT: The voltage between terminal #2 and ground should be approximately 0 volt.

DIAGNOSTIC TROUBLE CODE INFORMATION

Condition

If the control unit registers no signal/signal too low on relay coil (2/116) when the window lift in rear LH door is activated upwards, diagnostic trouble code CEM-6D03 is set.

Substitute Value

- None.

Possible Source

- Oxidation on relay socket contacts.
- Relay is loose or missing.
- Relay fault, open circuit/short circuit to ground in relay coil (meaning that window lift will not activate).
- Defective control unit.

Fault symptom[s]

- Electric window lift does not work.

SIGNAL TOO LOW. INTERMITTENT FAULT

CHECKING THE CONTROL MODULE FOR OPEN-CIRCUITS

Remove relay 2/116.

Check the driver circuit for the relay coil for an intermittent open-circuit as follows:

Measure the voltage between terminals #1 and #2 on the relay base. For further information about intermittent open-circuits, see **OPEN-CIRCUIT, INTERMITTENT FAULTS** .

Activate the relay driver, window up: Use the VCT2000 (or appropriate scan tool).

HINT: The voltage between terminals #1 and #2 should be battery voltage.

If the value deviates excessively, check the voltage between terminal #2 and the battery and between terminal #1 and ground. Both should equal battery voltage. Check for an intermittent open-circuit according to **OPEN-CIRCUIT, INTERMITTENT FAULTS** . Do not forget to check that the power supply to the control module is OK.

CHECKING AND REPLACING THE COMPONENT

Replace the relay, 2/119.

Activate the relay using the button on the control panel on the right rear door, window down.

If the function is OK, the cause of the fault was a damaged relay (short-circuit in the relay).

CEM-6D0C: RELAY, WINDOW LIFT RR DOWN. SIGNAL TOO LOW. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE INFORMATION

Condition

If control unit registers no signal/signal too low on relay coil (2/119) when the window lift in rear RH door is activated downwards from rear door switch unit, diagnostic trouble code CEM-6D0C is set.

Substitute Value

- None.

Possible Source

- Oxidation on relay socket contacts.
- Relay is loose or missing.
- Faulty relay, open circuit/short circuit to ground in relay coil.
- Defective control unit.

Fault symptom[s]

- Electric window lift does not work.

SIGNAL TOO LOW. INTERMITTENT FAULT

CHECKING THE CONTROL MODULE FOR OPEN-CIRCUITS

Remove relay 2/119.

Check the driver circuit for the relay coil for an intermittent open-circuit as follows:

Measure the voltage between terminals #1 and #2 on the relay base.

see **CHECKING WIRING AND TERMINALS. INTERMITTENT FAULTS**

Activate the relay driver for the right rear window down: Use the VCT2000 (or appropriate scan tool).

HINT: The voltage between terminals #1 and #2 should be battery voltage.

If the value deviates significantly, check voltage between #2 and battery voltage as well as between #1 and ground. Both shall be equal to battery voltage. Check for an intermittent open-circuit. See **CHECKING WIRING AND TERMINALS. INTERMITTENT FAULTS** Do not forget to check that the power supply to the control module is OK.

CEM-6F71: SWITCH, FUEL TANK FILLER COVER. SIGNAL TOO LOW (2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION

Condition

The central electronic module checks if the button for opening the fuel tank filler cover has stuck.

Diagnostic trouble code (DTC) CEM-6F71 is stored in the central electronic module if the it registers that the button for opening the fuel tank filler cover is pressed in for longer than 60 seconds.

Diagnostic trouble code (DTC) CEM-6F71 can be detected when the battery voltage is > 10.5 volt.

Substitute Value

- None.

Possible Source

- The button has jammed in the pressed in position
- Defective lamp switch module.

Fault symptom[s]

CEM-8A01: INVALID SWITCH POSITION FOR THE LIGHT SWITCH. FAULTY POSITION (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-8A01

Condition

Fig. 397: Identifying Light Switch Module (LSM)
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) communicates with the light switch module (LSM).

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) receives information from the light switch module (LSM) that the light switch is not in an approved position. For example it is in-between the position for parking lamps and low beam.

The voltage in the central electronic module (CEM) must exceed 10 V for at least 1 second in order for the diagnostic trouble code (DTC) to be detected.

The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.

Substitute Value

- Low beam always on.

Possible Source

- Fault in the communication with the light switch module (LSM)
- Damaged light switch module (LSM).

Fault symptom[s]

- The low beam is constantly lit.

FAULTY POSITION

CHECKING THE CONTROL

The diagnostic trouble code (DTC) is stored when the button or switch has been pressed in for too long or is in a non-approved position.

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up or can be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.

Check that the button or the switch is not sticking, jammed in the activated position or in a non-approved position.

Remedy as necessary.

CEM-8A02: MAIN BEAM RELAY. SIGNAL TOO HIGH. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE INFORMATION

Condition

Main beam relay must be activated to display the diagnostic trouble code. If the central electronic module (CEM) indicates that the main beam is short circuited to the battery voltage, diagnostic trouble code CEM-8A02 is displayed.

Possible Source

- The main beam relay circuit is short circuited to voltage supply.

Fault symptom[s]

- Front lamp is not working.

SIGNAL TOO HIGH/SIGNAL MISSING. INTERMITTENT FAULT

CHECKING THE RELAY

Check that relay 2/63 is installed correctly.

At the same time check the relay connections, in particular 2/63 2, for an intermittent short circuit to voltage supply as described in, see **SHORT-CIRCUIT TO SUPPLY VOLTAGE, INTERMITTENT FAULTS** , contact resistance and oxidation as described in **CONTACT RESISTANCE AND OXIDATION** and a loose connection as described in **LOOSE CONNECTIONS (TERMINALS)**

CEM-5B02: RH HEATING ELEMENT. SIGNAL FAULTY. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION

Condition

The central electronic module (CEM) communicates with the right-hand seat heating module (SHM).

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) receives information from the right-hand seat heating module (SHM) registering a fault in the heater pad.

The voltage in the central electronic module (CEM) must exceed 10.5 V for at least 1.5 seconds in order for the diagnostic trouble code (DTC) to be detected.

The diagnostic trouble code (DTC) can be diagnosed at key position II.

CEM-5F32: COOLANT TEMPERATURE SENSOR SHORT CIRCUIT TO GROUND (2003-2004)

DIAGNOSTIC TROUBLE CODE INFORMATION

Condition

Fig. 133: Identifying Engine Coolant Temperature Sensor

If the water temperature sensor circuit is short-circuited to ground, the control unit will interpret this as a fault and diagnostic trouble code CEM-5F32 will be set.

Substitute Value

- None.

Possible Source

- Signal wire short-circuited to ground.
- Defective water temperature sensor.

Fault symptom[s]

- Poor interior heating.

CHECKING COMPONENTS AND WIRING

Check the resistance of the engine coolant temperature sensor. For the resistance values, see **COMPONENTS RESISTANCE VALUES** .

Check the cable between control module terminal #16 and the signal terminal for the engine coolant temperature (ECT) sensor. Check for a short-circuit to ground. See **SHORT-CIRCUIT TO GROUND, PERMANENT FAULTS** .

HINT: It is difficult to separate the ground lead for the engine coolant temperature sensor from the signal cable. Therefore, measure one cable at a time and, see if the permitted values are present on either

of them.

Remedy as necessary.

Other information:

- To access the control module or connect the breakout box, see **CONNECTING THE BREAKOUT BOX**
- To access or replace the engine coolant temperature sensor, see **OVERHEAT PROTECTION THERMOSTAT / FLAME SENSOR / ENGINE COOLANT TEMPERATURE SENSOR, REPLACING**
- With the ignition on and the signal cable for the engine coolant temperature sensor cut, the voltage between the signal cable for the engine coolant temperature sensor (engine control module (ECM) side) and ground should be approximately 5 V
- For other values, see **SIGNAL SPECIFICATION** .

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-5F36

Condition

Fig. 145: Identifying Flame Sensor
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) checks the communication with the combustion preheater module (CPM).

The diagnostic trouble code is generated if Central electronic module (CEM) registers that the circuit for flame guard is short-circuited to ground.

The diagnostic trouble code (DTC) can be diagnosed when the heater is activated.

Substitute Value

CHECKING COMPONENTS AND WIRING

Check the cable between control module terminal #12 and water pump terminal 1. Check for a short-circuit to supply voltage.

The water pump must be replaced if no faults are found in the cable.

Remedy as necessary.

Other information:

- To access the control module or connect the breakout box, see **CONNECTING THE BREAKOUT BOX**
- To access or replace the water pump, see **WATER PUMP ENGINE COOLANT HEATER, REPLACING**
- With the ignition on and the water pump connector disconnected, the voltage between water pump terminal 1 (control module side) and ground should be approximately 0 V
- For other values, see **SIGNAL SPECIFICATION**
- see **CHECKING WIRING AND TERMINALS** .

The central electronic module (CEM) checks the communication with the combustion preheater module (CPM).

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the overheat protection thermostat has deployed.

The diagnostic trouble code (DTC) can be diagnosed when the heater is activated.

Substitute Value

- None.

Possible Source

- Air in the cooling system
- The cooling system is blocked
- Damaged overheat protection thermostat
- Damaged engine coolant temperature (ECT) sensor.
- Open circuit on fuel pump circuit.

Fault symptom[s]

INTERMITTENT FAULT

Check the combustion preheater module (CPM) connectors. Check for loose connections. Check for contact resistance and oxidation.

Check the circuit between combustion preheater module (CPM) terminal #11 and the components which are connected to the supply circuit (water pump terminal 2, fuel pump (FP) terminal 1 and combustion fan supply terminal). Check for an intermittent open-circuit. Check for an intermittent short-circuit to ground.

- Read off the engine coolant temperature.

NOTE: It is important that only the ignition is on in order for the heater to start.

- Activate the heater.

HINT: After repair, the voltage of the flame sensor can be checked. The voltage must be a maximum of 1.0 V.

Check the heater function.

CAUTION: In order for to enable start of the heater itself, the battery voltage must be normal, coolant temperature must be lower than +96 °C and the heater's after-run/stop sequence must be finished. There must also be enough fuel in the tank.

CAUTION: If the heater or other components are not activated, try starting the activation again using the VCT2000 (or appropriate scan tool).

DIAGNOSTIC TROUBLE CODE INFORMATION

Condition

Fig. 442: Fuel Pump, Water Pump, And Heater Fan Power Supply Diagram
Courtesy of VOLVO CARS CORPORATION

If the power supply from the control unit to the fuel pump, water pump and heater fan is short-circuited to ground or if there is an open circuit, the control unit will interpret this as a fault, and diagnostic trouble code CEM-5F43 will be set.

Substitute Value

- None.

Possible Source

- Contact resistance in control unit connector.
- Voltage supply circuit short-circuited to ground.

- Open circuit in power supply wire.

Fault symptom[s]

- Poor interior heating.

CEM-8A0A: EXTRA LAMP RELAY. SIGNAL MISSING. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE INFORMATION

Condition

Extra lamp relay should not have to be activated to display the diagnostic trouble code. If the central electronic module (CEM) shows that an extra lamp is fitted and there is an open circuit in the extra lamp circuit, diagnostic trouble code CEM-8A0A is displayed.

Possible Source

- Open circuit in extra lamp relay circuit.

Fault symptom[s]

- Front lights are not working.

CEM-8A0B: RELAY, DAYTIME RUNNING LAMP. SIGNAL TOO HIGH (2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION

Condition

The diagnostic trouble code (DTC) is stored if the control module registers a high signal from the status flag when activating the relay guide for the "day time running lamp" relay.

Diagnostic trouble code (DTC) CEM-8A0B can be detected at ignition on.

Substitute Value

- None.

Possible Source

- The relay guide for the "daytime running lamp" relay is short-circuited to battery voltage.

Fault symptom[s]

- The front lighting does not function.

CEM-8C12: REAR FOG SWITCH ACTIVATED TOO LONG (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-8C12

Condition

Fig. 89: Identifying Light Switch Module (LSM)
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) communicates with the light switch module (LSM).

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) receives information from the light switch module (LSM) indicating that it has detected that the switch for the rear fog lamps has been activated for more than 60 seconds.

The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.

Substitute Value

- None.

Possible Source

- Damaged switch for the rear fog lamps
- Fault in the communication with the light switch module (LSM).

Fault symptom[s]

- The rear fog lamp does not work.

ACTIVATED TOO LONG

CHECKING THE CONTROL

The diagnostic trouble code (DTC) is stored when a button or switch has been depressed for a long time.

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up or can be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.

Check that the button or switch does not stick in the activated position.

Remedy as necessary.

CEM-8C12: REAR FOG LAMP SWITCH. SIGNAL TOO LOW. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE INFORMATION

Condition

Rear fog lamp switch must be activated for at least 60 seconds for the diagnostic trouble code to be detected. If the central electronic module (CEM) detects that the rear fog lamp switch has been registered for 60 seconds, diagnostic trouble code CEM-8C12 is displayed.

Possible Source

- Faulty rear fog lamp switch.

Fault symptom[s]

- Rear fog lamp does not work.

CEM-8C13: FRONT FOG LAMP RELAY. SIGNAL TOO HIGH. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE INFORMATION

Condition

Front fog lamp relay must be activated to display the diagnostic trouble code. If the central electronic module (CEM) indicates that the front fog lamp is short circuited to the battery voltage, diagnostic trouble code CEM-8C13 is displayed.

Possible Source

- The front fog lamp relay is short circuited to voltage supply.

Fault symptom[s]

- Front fog lamp is not working.

CEM-8D01: IGNITION LOCK LIGHT AND EXTRA BRAKE LIGHT. SIGNAL TOO LOW. INTERMITTENT FAULT (2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION

Condition

For the diagnostic trouble code (DTC) to be stored, neither the ignition switch lighting or the stop (brake) lamp may be activated. Diagnostic trouble code (DTC) CEM-8D01 is stored if the central electronic module (CEM) indicates a short-circuit to ground in the high level additional stop (brake) lamp or the ignition ring lighting.

Possible Source

- Over heated.
- Short-circuit to ground in the circuit for the ignition switch or the stop (brake) lamp circuit.

- Defective high level stop (brake) lamp.

Fault symptom[s]

- The stop (brake) lamp does not light when the brake pedal is depressed.

SIGNAL TOO LOW. INTERMITTENT FAULT.

CHECKING THE WIRE

Check the wire between central electronic module (CEM) 17D and ignition lock light (16/65) 5 for an intermittent short circuit to ground as described in, see **SHORT-CIRCUIT TO GROUND, INTERMITTENT FAULTS** and for a loose contact as described in **LOOSE CONNECTIONS (TERMINALS)** .

Check the wire between central electronic module (CEM) 5B and high level brake light (10/19) 5 for an intermittent short circuit to ground as described in, see **SHORT-CIRCUIT TO GROUND, INTERMITTENT FAULTS** and for a loose contact as described in **LOOSE CONNECTIONS (TERMINALS)** .

Also check the connector.

CHECKING THE IGNITION LOCK WIRE

Fig. 105: Identifying Ignition OFF

- Ignition off.

  Apply the brake then release the brake to check whether the brake light works correctly. If the high level brake light is not working, the fault may be caused by overheating. Wait about 10 minutes and check whether the fault was caused by overheating.

  If the brake light works, the diagnostic trouble code may also be caused by a fault in the lighting circuit to the ignition lock. If the ignition lock light does not work correctly, check the wire between central electronic module (CEM) 19D and ignition lock light (16/65) 5 for a short circuit to ground as described in, see **SHORT-CIRCUIT TO GROUND, PERMANENT FAULTS** .

  Do the necessary corrective action.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-8D01

Condition

For the diagnostic trouble code (DTC) to be stored, either the ignition switch lighting or the stop lamp must be activated. Diagnostic trouble code (DTC) CEM 8D01 is stored if the central electronic module (CEM) indicates a short-circuit to ground in the high level additional stop lamp or in the ignition ring lighting.

Possible Source

- Over heated
- Short-circuit to ground in the circuit for the ignition switch or the stop lamp circuit
- Defective high level stop lamp.

Fault symptom[s]

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-8D01

Condition

Fig. 116: Identifying Central Electronic Module (CEM)
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) checks the stop lamps.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) detects that the signal from the lower brake lights is too low.

The diagnostic trouble code (DTC) can be diagnosed when the stop lamp is active.

Substitute Value

- If the fault has been detected in 200 ignition cycles, the output is closed permanently until the diagnostic trouble code is erased.

Possible Source

- The circuit between Central electronic module (CEM) and lower brake lights is short-circuited to ground.

Fault symptom[s]

- The stop lamp does not light when the brake pedal is depressed.

SIGNAL TOO LOW

CHECKING THE STATUS

Fig. 117: Identifying Ignition ON
Courtesy of VOLVO CARS CORPORATION

- Ignition on.

  Activate the stop lamp.

  Check if the fault is permanent or intermittent.

  The stop lamp must light on activation.

  The fault is permanent if the stop lamp does not activate.

  If the stop lamp is activated, this is an indication that the fault was present previously but that it is not

active at the moment, i. e. the fault is intermittent.

  Refer to **CHECKING COMPONENTS AND WIRING**

CHECKING COMPONENTS AND WIRING

When too low voltage has been detected, the Central electronic module (CEM) turns off the output to the next ignition cycle. If low voltage has been detected in 200 ignition cycles, the Central electronic module (CEM) is closed by the output until the DTC is erased.

HINT: Erase the diagnostic trouble code, turn off and on the ignition and read out the diagnostic trouble codes again. If the fault has disappeared, the output activates and then the brake light when the brake pedal is depressed. Otherwise the DTC will be stored again.

Check the voltage between the left and right-hand stop lamps and the output on the rear electronic module (REM). The voltage must be approximately 12 V when the stop lamp is activated.

Check the cable between central electronic module (CEM) terminal #A15 (15) and rear electronic module (REM) terminal #A18 (18). Check for a short-circuit to ground.

Check the cable between Rear electronic module (REM) and brake lights with regards to short-circuiting to ground.

HINT: Disconnect the cable between the Rear electronic module (REM) and the brake lights to ensure that the cable between the Central electronic module (CEM) and Rear electronic module (REM) is OK.

Remedy as necessary.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-8D02

Condition

For diagnostic trouble code (DTC) CEM-8D02 to be stored, neither the ignition switch lighting or the stop lamp may be activated.

Diagnostic trouble code (DTC) CEM-8D02 is stored if the central electronic module indicates a short-circuit to supply voltage or an open-circuit in the high level stop lamp or the ignition switch lighting.

Possible Source

- Open-circuit in the circuit for the ignition switch or the high level stop lamp
- Short-circuit to supply voltage in the circuit for the ignition switch or the high level stop lamp
- Defective ignition switch lighting
- Defective high level stop lamp.

Fault symptom[s]

- The stop lamps do not light when the brake pedal is pressed
- The stop lamp lights constantly.

STOP LAMP, REAR WINDSHIELD, REPLACING

Special tools:

see **9512636**

REMOVING THE STOP LAMP

USE CLEAN GLOVES

To avoid customer complaints:

- gloves which leave no prints must be used
- visible surfaces, where the stop lamp can cover the rear windshield, must be kept unmarked and fault-free
- visible surfaces on the stop lamp must be kept unmarked and fault-free.

PREPARATORY WORK

Fig. 136: Clips, Rear Interior Lighting And Rubber
Courtesy of VOLVO CARS CORPORATION

Remove:

- three rear clips (1) in the headlining by twisting a quarter of a turn and pulling it out
- the rear interior lighting (2). The mounting mechanism consists of metal springs
- foam rubber (3) from the top of the headlining. Be careful. It must be reused.

NOTE: Note the position of the foam rubber.

- connector (4) from the stop lamp
- stop lamp wiring. Pull it out through the hole for the rear interior lighting.

REMOVING THE STOP LAMP

Fig. 137: Identifying Stop Lamp Removal
Courtesy of VOLVO CARS CORPORATION

WARNING: The stop lamp must be removed from the headlining. Do this carefully as the headlining is made of corrugated cardboard.

Use a weatherstrip tool to cut as close to the stop lamp tape as possible. This is to avoid damaging the headlining.

Start with the two pieces of tape on the section that points forwards. Then cut the two pieces of tape closest to the rear windshield.

Do one corner at a time.

IDENTIFICATION

IDENTIFYING THE STOP LAMP

Fig. 138: Identifying Stop Lamp
Courtesy of VOLVO CARS CORPORATION

A **version 1** stop lamp can be identified as follows:

- The P/N (1), stamped onto the left-hand side of the stop lamp, is 9154503
- the connector (1) on the stop lamp has a smooth surface facing downwards and an enclosing collar.

A **version 2** stop lamp can be identified as follows:

- The P/N (2), stamped onto the left-hand side of the stop lamp, is 9483132
- the connector (2) on the stop lamp has a smooth surface facing upwards.

REMOVING LOOSE PAPER

Remove loose paper from the inside of the headlining where the stop lamp was located.

NOTE: Do not damage the headlining.

REPLACING THE STOP LAMP TO THE SAME MODEL

If the stop lamp is being replaced with one of the same model, no modifications need to be made. Continue with:**INSTALLING COMPONENTS**.

REPLACING THE STOP LAMP, VERSION 1 TO VERSION 2

If a version 1 stop (brake) lamp is replaced with a version 2 stop (brake) lamp (see, see **IDENTIFICATION**) the cables should exchange positions (change polarity). See **REVERSING POLARITY OF CABLES**.

REVERSING POLARITY OF CABLES

OPENING THE SECONDARY CATCH

Fig. 139: Identifying Opened Secondary Catch
Courtesy of VOLVO CARS CORPORATION

Use a thin screwdriver with a 3-4mm wide blade.

Carefully undo the hooks on the secondary catch.

REMOVING CABLE

Fig. 140: Extracting Cable Terminal -- Double Cavity Row
Courtesy of VOLVO CARS CORPORATION

NOTE: Transfer one cable at a time.

Press the cable terminal through the cavity.

Insert the terminal removal tool see **9512636** from the contact side into the upper cavity bank, by the cable terminal. The beveled side of the tool should face sideways.

Extract the cable terminal.

Repeat for each cable.

CHECKING THE CABLE TERMINAL

Fig. 141: 0. 64 Socket
Courtesy of VOLVO CARS CORPORATION

Inspect the locking tabs on the terminal for damage. Check that the tabs are not pressed inward.

INSTALLING THE CABLE

Fig. 142: Identifying Cable Terminal Inserted In Housing
Courtesy of VOLVO CARS CORPORATION

Use a new connector, P/N 978305.

Install the yellow-red cable in terminal 1.

Install the brown cable in terminal 5.

When the cable terminal is inserted in the cavity a click is often heard when the primary catch engages.

Pull the cable gently to check that the cable terminal is properly seated in the cavity.

CLOSING THE SECONDARY CATCH

Fig. 143: Closing Housing
Courtesy of VOLVO CARS CORPORATION

When the secondary catch is closed a click is often heard.

If it cannot be closed this might be because the cable terminal is not completely inserted in the cavity.

INSTALLING COMPONENTS

TESTING THE STOP LAMP

Fig. 144: Connecting Stop Lamp
Courtesy of VOLVO CARS CORPORATION

Connect a new stop lamp.

Check its function.

Disconnect it.

REMOVING THE BACKING

Fig. 145: Double Sided Adhesive Backing
Courtesy of VOLVO CARS CORPORATION

Remove the backing (1) from the double-sided adhesive tape on the stop lamp.

INSTALLING THE STOP LAMP

Fig. 146: Identifying Stop Lamp Positioned On Headlining With Bevel
Courtesy of VOLVO CARS CORPORATION

Position the stop lamp on the headlining with the bevel (1)**against** the headlining.**Do not** allow the double-sided adhesive tape touch the headlining.

NOTE: **To avoid squeaking it is important that the stop lamp is correctly positioned on the headlining.**

Press the stop lamp into place on the headlining.

FINISHING WORK

Fig. 147: Identifying Stop Lamp Components
Courtesy of VOLVO CARS CORPORATION

Connect the connector (1) to the stop lamp.

Tape (2) stop lamp wiring to the headlining so that they cannot make a noise.

Install foam rubber (3), just behind the hole for the rear interior lighting. Use contact adhesive, P/N 1161434, if there is too little adhesive left on the foam rubber for it to stick to the headlining.

Install clip (4) in the headlining by pressing straight up and twisting a quarter turn.

Install the interior lighting (5) by pressing straight up.

FUNCTION TEST

CHECKING THE STOP LAMP

Check the function of the stop lamp with the low beam on and the turn signal lamp activated.

Check the function of the interior lighting.

The central electronic module (CEM) checks the stop lamps.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the signal from the stop lamps is faulty.

The diagnostic trouble code (DTC) can be diagnosed when the stop lamp is active.

Substitute Value

- None.

Possible Source

- Open-circuit in the circuit for the stop lamps.

Fault symptom[s]

- The stop lamp does not light when the brake pedal is depressed.

FAULTY SIGNAL

CHECKING THE STATUS

Fig. 149: Identifying Ignition ON

- Ignition on.

  Activate the stop lamp.

  Check if the fault is permanent or intermittent.

  The stop lamp must light on activation.

The fault is permanent if the stop lamp does not activate.

If the stop lamp is activated, this is an indication that the fault was present previously but that it is not active at the moment, i. e. the fault is intermittent.

CHECKING COMPONENTS AND WIRING

Check the voltage between the left and right-hand stop lamps and the output on the rear electronic module (REM). The voltage must be approximately 12 V when the stop lamp is activated.

Check the control signal cable. Check for an open-circuit. Check for a short-circuit to supply voltage.

Take readings between:

- Rear electronic module (REM) terminal #B3 (#3) and stop lamp terminal #A5.

Check the cable between central electronic module (CEM) terminal #A15 (15) and rear electronic module

(REM) terminal #A18 (18). Check for a short-circuit to supply voltage. Check for an open-circuit.

Remedy as necessary.

CEM-8D03: BRAKE LIGHT SWITCH INTERNAL FAULT (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-8D03

Condition

The central electronic module (CEM) checks the signal from the stop lamp switch.

The diagnostic trouble code (DTC) is stored if the control module detects that:

- Brake light is activated when Engine control module (ECM) informs that brake pedal is not depressed, and no internal error has been detected of Central electronic module (CEM).

The control module's test for the diagnostic trouble code (DTC) starts in the event of:

- Ignition position I and II, when HS-CAN is activated.

NOTE: The control module can only detect the fault once the test has been started and the diagnostic trouble code (DTC) is stored when the conditions are met.

Substitute Value

- None.

Possible Source

- Internal error in brake light switch or leads.

Fault symptom[s]

- Cruise control/Does not engage
- Cruise control/Disengagement does not work
- Cruise control/Does not remain at set speed/disengages

- Tail light/Brake lights constantly lit

CHECKING STOP LAMP SWITCH STATUS

NOTE: The following troubleshooting shall not be performed if no symptom (according to trouble code information) is noticed on the vehicle. Then the diagnostic trouble code shall be erased instead.

This diagnostic trouble code indicates that there is a defect in the brake light switch or the leads to the same.

Brake light switch is a switch that controls when the brake lights shall be activated/not activated.

Troubleshoot according to:

1. Check the brake light switch connector for contact resistance and oxidation.

2. Check that the brake light switch is supplied with voltage.

3. Check leads between Central electronic module (CEM) and brake light switch.

If no defect is detected, replace brake light switch.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-8D04

Condition

The central electronic module (CEM) checks the signal from the stop lamp switch.

The diagnostic trouble code (DTC) is stored if the control module detects that:

- Brake light is activated when Engine control module (ECM) informs that brake pedal is not depressed, and Central electronic module (CEM) detects abnormal current to brake light.

The control module's test for the diagnostic trouble code (DTC) starts in the event of:

- Ignition position I and II, when HS-CAN is activated.

NOTE: The control module can only detect the fault once the test has been started and the diagnostic trouble code (DTC) is stored when the conditions are met.

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-8E01

Condition

Fig. 158: Identifying Back-Up (Reversing) Lamp Switch
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) checks the back-up (reversing) lamp switch.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the signal in the circuit for the back-up (reversing) lamp switch is too low when gears 1 to 5 are selected and vehicle speed is above 80 km/h.

The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute Value

- None.

Possible Source

CEM-8F04: TURN SIGNAL LAMP. FAULTY SIGNAL (2005-2012)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION CEM-8F04

Condition

Fig. 201: Identifying Steering Wheel Control Module
Courtesy of VOLVO CARS CORPORATION

The central electronic module (CEM) checks the turn signal lamps.

The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the signal from the switch for the turn signal lamps is faulty.

The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute Value

- None.

Possible Source

- Damaged switch for the turn signal lamps
- Internal fault in the steering wheel module (SWM).

Fault symptom[s]

- The turn signal lamps do not work.

FAULTY SIGNAL

CHECKING THE STATUS

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the steering wheel module (SWM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. If the diagnostic trouble code (DTC) recurs, replace the turn signal lamp switch.
