FAULT TRACING

FAULT TRACING

SIGNAL MISSING

GENERAL INFORMATION

NOTE: Illustrations shown are only examples.

HINT: For general information about CAN-troubleshooting, see: GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK

General about CAN-related diagnostic trouble codes.

CEM-DF01 - DF17 can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. tart with these diagnostic trouble codes first.

CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). he control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). his diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

NOTE: In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. or certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery o "restart" the control module/CAN-net.

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. here will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

NOTE: **Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.**

- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. he resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

HINT: For HS-CAN the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

NOTE: **Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules.**

Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. o measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. he values shall be as above.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. or certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery o "restart" the control module/CAN-net.**

- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal

communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #4 (ground). he voltage should be approx:2, - 3, V.
- #14 and #4 (ground). he voltage should be approx:1, - 2, V.
- #6 and #14. he voltage shall be between approx. 0.55-1.4 V. he voltage shall normally be between 0.55 - 0.90 V. higher voltage may indicate increased traffic on the CAN-net. n case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

NOTE: After fault with control modules that interfere with communication, other control modules may remain in Limp-Home even when the ignition has been turned off and on a few times. or certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery o "restart" the control module/CAN-net.

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net etc., are examples of such faults. he tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 as well as associated TJ 20402.

- Ignition on.
- Connect DiCE to the diagnostics socket.
- Note the blue LED-indicator. he indicator flashes to show detection of fault messages.

NOTE: Certain interference may occur without any real fault

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

IDENTIFYING A CONTROL MODULE IN THE CAN NETWORK

Fig. 6: Identifying Ignition ON

For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

HINT: DiCE can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. he tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools:951 3010 (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: **It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.**

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. he average value of the voltage must be approximately 0.6-1.4 V. he voltage shall normally be between 0.55 - 0.90 V. higher voltage may indicate increased traffic on the CAN-net. n case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. he easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: **When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.**

HINT: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. witch off the ignition between each check.

NOTE: **Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.**

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. or certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery o "restart" the control module/CAN-net.**

  Checking for a short-circuit to ground

  Measure resistance between the following connections on the OBDII-box/diagnostics socket.

  - #6 and #4 (ground). Measurement is shown in the illustration. he resistance should be above 1 kohms.
  - #14 and #4 (ground). he resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #16 (voltage). Measurement is shown in the illustration. he resistance should be above 1 kohms.
- #14 and #16 (voltage). he resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

HINT: Part the CAN-net at suitable points to decide where a short-circuit may be found.

NOTE: **After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. or certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery o "restart" the control module/CAN-net.**

- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

  For general information about CAN-troubleshooting, see: **GENERAL INFORMATION ABOUT FAULT-TRACING IN THE CAN NETWORK**

  In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. his means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. f there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.., contact resistance in a connector or branching, communication may be lost/interfered with.

  Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.

  Carry out the following:

  Measure voltage between the following connections on the OBDII-box/diagnostics socket.

  - #6 and corresponding connection on relevant control module for CAN-H. he voltage shall be lower than 50 mV.
  - #14 and corresponding connection on relevant control module for CAN-L. he voltage shall be

lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. heck the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

ELECTRICAL

ACTIVATING COMPONENTS/FUNCTIONS

ACTIVATION OF COMPONENTS

Using this facility, a number of components can be activated to check their function. The following components can be activated:

GLOW PLUG

Activating the glow plug.

NOTE: Important: This function should be activated for no longer than 10-20 seconds.

HEATER FAN

Activating the heater fan.

A "buzzing" noise is heard from the heater fan when it is activated.

FUEL PUMP

Activating the fuel pump.

A "buzzing" noise is heard from the fuel pump when it is activated.

WARNING: The fuel pipe shall only be filled when replacing the pipe. If you fill with fuel for too long, there is a risk of smoke development or heater damage. However, it is necessary to fill the pipe when replacing the fuel pipe as the control unit only permits 3 heater start attempts. It shall take a maximum of 8-10 minutes to fill up with fuel when replacing the pipe.

WATER PUMP

Activating the water pump.

A "buzzing" noise is heard from the water pump when it is activated.

HEATER

Activating the heater.

In case of too low battery voltage or if the heater is in a state that prohibits activation, the heater will abort the activation. In order to enable start of the heater itself, battery voltage shall be normal, coolant temperature must be lower than +96 °C, and the heater's post-run/stop sequence must be completed. There must also be enough fuel in the tank.

CAUTION: If the heater or other components are not activated, try closing down the activation window and then starting the activation again using the VCT2000 (or appropriate scan tool).

COMPONENT SUPPLY VOLTAGE

Activating the relay that provides supply voltage to the water pump, fuel pump and heater fan.

CHECK POWER STEERING FLUID, COOLANT ETC. IN THE GENERATOR (2003-12)

CHECK POWER STEERING FLUID, COOLANT ETC. IN THE GENERATOR

If, for any reason, there is power steering fluid, coolant etc on the generator's carbon brushes, slip rings or windings, there may be no charge.

Check for signs of oil or fluid on the outside of the reservoir, pump, pipe and hoses as well as on the generator. In the event of suspected spillage, remove the generator and check carbon brushes, slip rings and windings. If oil or fluid spillage is clearly visible the generator or parts of the generator must be replaced. If the cause of oil or fluid spillage is due to damaged parts, these must be replaced.

Remedy as necessary.

- Oil or fluid in the generator.

Fault symptom[s]

- The battery discharges
- The "Generator not charging" warning lamp is lit when the engine is running.

CHECKING FOR NOISE FROM THE STARTER MOTOR (2003-12)

CHECKING FOR NOISE FROM THE STARTER MOTOR

CHECKING FOR NOISE

Check for noise from the starter motor when a start is attempted. Only an "engagement sound" should be heard.

Noise can come from the starter mechanism, the electric motor and the bearing as well as from the starter collar and carrier.

When start attempts are stopped the starter motor should stop immediately without any noise.

In the event of noise, the starter motor or the starter collar or carrier should be replaced.

Remedy as necessary.

HINT: For vehicles with automatic start/stop of engine, the output and torque of the starter motor is increased. In addition, the gear ratio is changed, which means that the starter motor runs at higher speeds. This can cause the starter motor for vehicles with automatic start/stop of engine to be perceived as more audible.

If the starter motor bearing or starter drive and drive unit are defective, noise may occur when a start is attempted.

Possible Source

- Defective starter motor
- Defective starter collar or carrier.

Fault symptom[s]

- Noise from the starter motor.

CHECKING POWER CONSUMING COMPONENTS WHEN DRIVING (2003-12)

CHECKING POWER CONSUMING COMPONENTS WHEN DRIVING

If the belt or belt tensioner is defective, the belt can slip at the belt pulleys, which means that the power that is to be transferred becomes friction heat between the belt and the pulley.

Possible Source

- Damaged auxiliary unit belt and belt tensioner.

Fault symptom[s]

- The battery discharges
- The "Generator not charging" warning lamp lights when the ignition is switched on
- Noise from the generator (GEN)
- Noise from the belt transmission.

CHECKING THE BATTERY

Check the battery. See **FAULT-TRACING AND TESTING THE BATTERY** . Check that the battery has the correct specification for the model.

Try a new battery if the specification is not OK.

NOTE: **If the car is equipped with a battery of different specification to the recommended battery but the battery is fault free, do not replace the battery.**

FAULT-TRACING AND TESTING THE BATTERY

NOTE: **As the graphics in this service information are used for different model years and/or models, some variation may occur. However, the essential information in the graphics is always correct.**

WARNING: **Oxyhydrogen is formed when batteries are being charged. Oxyhydrogen is extremely explosive. Smoking, welding, grinding and naked flames in the vicinity of the battery may result in the battery exploding causing personal injury and damage to the car. Only charge the battery in a well ventilated area. Ensure that ventilation is good**

WARNING: **Watch out for acid splash The battery contains sulfuric acid which can cause serious corrosive damage. If the electrolyte comes into contact with your eyes, skin or clothes - flush using large quantities of water. Contact a doctor immediately if acid splashes into eyes Use protective goggles when handling batteries.**

CLEANING AND CHECKING BATTERIES

CLEANING AND CHECKING BATTERIES EXTERNALLY

Fig. 13: Identifying Battery

Cleaning

- Remove the battery from the car. Always disconnect the negative terminal first to prevent sparking
- Check that the battery is clean. Dirt can cause leakage currents between the battery posts
- Wash the battery using water. A mild cleaning agent can be used if necessary. Ensure that no dirt or water penetrates any of the cells
- Wipe clean and dry.

External checks

- Check the battery for signs of the following damage and remedy as necessary:
  - Dirty or loose posts
  - The battery is not secure and is loose in the engine compartment or cargo compartment
  - Worn, oxidized or damaged battery leads.

- Discard the battery if any of the following faults are found:
  - Cracked container

- Leakage
- Bent, loose or damaged terminals
- Battery damaged by freezing.

- Reinstall the battery in the car after checking it. Connect the positive terminal first
- Check that the battery is secure in the engine compartment or cargo compartment.

WARNING: The battery can develop oxyhydrogen, which is highly explosive. Ensure that any evacuation hose (the hose which evacuates oxyhydrogen from the cargo compartment) is correctly connected to the battery and that the hose leads downwards to the dedicated outlet in the bodywork

CHECKING THE ELECTROLYTE LEVEL

Check the electrolyte level. Top up the electrolyte if necessary. To check and top up, see **BATTERY ACID LEVEL, CHECKING** .

ALTERNATIVE TEST METHOD

NOTE: **This method does not apply to North American dealers. North American dealers must always follow the Volvo Battery Analyzer 3100/3200 test method.**

Follow the steps below:

1. Checking the density of the acid

The density of the acid can be measured using an electrolyte gauge or a refractometer on the battery at room temperature.

Measure the density in all the cells. Check the following:

- If the density is above 1.225 g/cm^3 in each cell and the difference in density between the cells is less than 0.03 g/cm^3 , the battery must be tested for load. See point 4 below, *Load check*
- If the density is below 1.225 g/cm^3 in each cell and the difference in density between the cells is less than 0.03 g/cm^3 , the battery must be charged. See **BATTERY, CHARGING**
- If the density in two adjacent cells is considerably lower than in other cell (i. e. if the difference is greater than 0.03 g/cm^3 , there is probably leakage between the two cells. Discard the battery
- If the density is markedly lower in only one cell, the fault is probably a short-circuit. Check the battery acid for discoloration. Discard the battery.

2. Checking the stand-by voltage

Check the stand-by voltage as follows:

- Disconnect the cable from the battery negative terminal
- Leave the battery disconnected for at least 2 hours
- Measure the stand-by voltage using a digital multimeter. The battery must be recharged immediately if the stand-by voltage is lower than 12.45 V. For information about charging, see **BATTERY, CHARGING**
- If the car has not been delivered to a customer - update the Battery Maintenance Card, as shown
- Connect the battery negative terminal.

3. Charging

If the battery is not charged, it must be charged according to **BATTERY, CHARGING** .

Check that the battery takes the charge.

- If the charge is OK, the battery must be load tested. See point 4, *Load check*
- The battery may be sulfated if it does not charge. Sulfating means that the battery is damaged due to insufficient charge. Discard the battery.

4. Load check

During a load test, the load current must rise to at least 3 times the battery capacity in amperes (A).

For example: A battery with a capacity of 60 Ah must be loaded with a current of 180 A (= 3 x 60).

Read off the battery voltage after approximately 15 seconds. The voltage must then be 9.6 V. If this voltage is not reached there may be an open-circuit or a short-circuit in the battery.

- An **open-circuit** can be identified, for example, by the voltage dropping rapidly towards 0 V when the battery is loaded, or if the voltmeter does not give a reading when connected to the battery. Discard the battery if there is an open-circuit
- A **short-circuit** is most often evident under load when the short-circuited cell or cells begin to boil. Discard the battery if there is an short-circuit.

5. Self-discharge

If the battery has been checked according to points 1-4 above, but is not showing signs of the above faults, set the battery to self-discharge to check that the self-discharge is normal.

If the battery self-discharges abnormally and does not retain a charge for more than a couple of days, this may be a sign of a potential short-circuit. Discard the battery.

- Check the voltage of the **battery** while the starter motor is operating by temporarily short-circuiting the cables to each other so that the control solenoid is powered and the starter motor engages. Make a note of the value.

NOTE: Do not bridge directly in the relay base or the connections in the base may be damaged.

HINT: A starter motor relay without a protective cover can be used to create the short-circuit. Closes the switches manually.

The voltage can vary slightly depending on the engine compression action, therefore an average value should be taken

- Connect a voltmeter between the starter motor power supply terminal #1 (30) and the cylinder block
- Check the voltage across the **starter motor** while the starter motor is operating by temporarily short-circuiting the cables to each other so that the control solenoid is powered and the starter motor engages. Make a note of the value.

NOTE: Measure the voltage between the battery's positive pole and negative pole, as well as between the power supply to the starter motor terminal #1(30) and the starter motor's ground as shown.

The **difference** between the voltage at the battery and the starter motor respectively must **not** exceed 1 V. If the difference is greater it indicates excessively high resistance in the supply voltage to the starter motor and in the ground circuit from the battery.

When the voltage drop is too high it indicates excessively high resistance in the circuit.

The ground terminals on a car are a vital part of the car electrical system as all sub-system voltage levels have the ground terminal as a reference (as 0 V). The three illustrations show the ground terminal screwed connections to the cylinder block (the left-hand illustrations) and to the chassis (right-hand illustration), and the path of the current in the joint. A poor contact on the ground terminal will have a negative impact on the car electrical systems. It is therefore very important that the ground terminal contact is in good order, that the screws are tight and the cable terminals are correctly crimped to the cable. Ground terminals where several cables are connected to one ground terminal are especially important.

NOTE: There should be no corrosion between the cable terminals and the screw head.

Check the starter motor terminal for power supply and the terminal for grounding to the cylinder block. Check for contact resistance and oxidation. Check the connection of the terminal to the cable in particular.

Check the engine ground terminal. Check for contact resistance and oxidation. Check the connection of the terminals to the cables in particular.

Check the start assistance terminals in the engine compartment. Check for contact resistance and oxidation. Check the connection of the terminals to the cable in particular.

CABLE TERMINALS SURFACE TREATMENT

GENERAL INFORMATION

Fig. 40: Identifying Terminal With Integrated Cable
Courtesy of VOLVO CARS CORPORATION

Terminal with integrated cable designated "cable terminal", certain cases "service terminal".

Fig. 41: Identifying Terminal With Integrated Cable
Courtesy of VOLVO CARS CORPORATION

Black marking = terminal's surface treatment is gold. Marking introduced running from second quarter 2008.

CAUTION: If new components are supplied with a section of new wiring, the equivalent wiring section in the vehicle must be substituted with the new section.

Due to oxidation and galvanic currents, female and male connections with the same surface treatment should be used.

Example of different surface treatments: Gold (Au), Silver (Ag), Tin (Sn)

- Silver + Tin = Permitted
- Tin + Gold = Not permitted
- Silver + Gold = Permitted

The type of surface treatment on the connector can only be determined by inspection the male connector's pins with a magnifying glass.

CHECKING THE CONTROL SOLENOID AND STARTER MOTOR

PREPARATORY CHECKS

There are three starter motor checks that should be performed to avoid extra work.

The checks are and should be troubleshooted in the following order:

1. Checking voltage drop in the starter motor and battery circuits
2. Checking solenoid and starter motor
3. Checking the starter motor

Before continuing troubleshooting of the starter motor, check as above.

- **Continue**

  see **CHECKING TERMINAL**

CHECKING TERMINAL

NOTE: To carry out this test, the battery must be fault free and the starter motor relay

must be checked and there must be no diagnostic trouble codes (DTCs) stored for the symptom.

WARNING: **If the engine cooling fan (FC) is running, wait until it has stopped.**

Fig. 43: Identifying Ignition OFF

- Ignition off.
- The gear lever shall be in neutral position.
- Parking brake applied.
- Check the fuse for the starter motor.

Check terminal #1(30). Check for:

- Damaged terminal.
- Loose terminal.
- Rust, oxidation or other deposit.

Remedy as necessary.

Check terminal #2(50). Check for:

- Damaged terminal.
- Loose terminal.
- Rust, oxidation or other deposit.

The terminal must be replaced if any of the above faults are found on terminal #2(50).

When replacing, connection with P/N 30765120 must be used. The terminal is supplied with corresponding cable. The cable must be adapted to a suitable length. The cable must not be stretched when the terminal is installed.

Remedy as necessary.

- Reconnect the connectors and relay
- Connect a voltmeter to control solenoid terminal #2 (50)
- Check the voltage at the start position.

  If the voltage falls below approximately 9 V in the cranking position, there is a voltage drop in the wiring circuit for the solenoid.

  Select an alternative to continue

2. The voltage dropped too low in the cranking position. A fault was found. Troubleshooting has been completed.
3. No fault detected during the test. Troubleshooting has been completed.

CHECKING VOLTAGE DROP IN THE STARTER MOTOR AND BATTERY CIRCUITS

NOTE: The conditions for this test are that:

- **The battery is fully charged**
- **The car and engine temperatures exceed 20°C (68°F).**

WARNING: If the engine cooling fan (FC) is running, wait until it has stopped.

- Ignition off
- Select neutral (automatic transmissions: "N"). Apply the parking brake
- Expose the starter motor relay in the integrated relay/fusebox in the engine compartment. For the location of the relays, see the wiring diagram. Remove the relay
- Expose the battery
- Connect a voltmeter between the battery positive and negative terminals
- Temporarily connect two cables to relay base terminals #3 (30) and #5 (87)
- Check the voltage of the **battery** while the starter motor is operating by temporarily short-circuiting the cables to each other so that the control solenoid is powered and the starter motor engages. Make a note of the value!

NOTE: Do not bridge directly in the relay base or the connections in the base may be damaged.

HINT: A starter motor relay without a protective cover can be used to create the short-circuit. Closes the switches manually.

The voltage can vary slightly depending on the engine compression action, therefore an average value should be taken

- Connect a voltmeter between the starter motor power supply terminal #1 (30) and the cylinder block
- Check the voltage across the **starter motor** while the starter motor is operating by temporarily short-circuiting the cables to each other so that the control solenoid is powered and the starter motor engages. Make a note of the value.

NOTE: Measure the voltage between the battery's positive pole and negative pole, as well as between the power supply to the starter motor terminal #1 (30) and the starter motor's ground as shown.

The **difference** between the voltage at the battery and the starter motor respectively must **not** exceed 1 V. If the difference is greater it indicates excessively high resistance in the supply voltage to the starter motor and in the ground circuit from the battery.

CHECKING THE STARTER MOTOR

There is an internal fault in the starter motor if the starter motor does not function despite having power supply.

Check the brush holders and carbon brushes for the starter motor. Check for wear.

Check if the starter motor rotor or other components have jammed so that the starter motor is blocked.

HINT: If the starter motor is blocked the interior lighting will dim when the starter motor is activated.

Try a new starter motor if no fault is found.

CHECKING THE FREEWHEEL ON A GENERATOR (GEN) (2003-06)

CHECKING THE FREEWHEEL ON A GENERATOR (GEN)

NOTE: **This test is only carried out if the generator (GEN) is equipped with a freewheel. The cover over the pulley nut in the center of the pulley indicates whether a freewheel is installed.**

Check the function of the free wheel as follows.

Checking the function of the freewheel on the generator (GEN) in the car

- Ensure that no extra power consuming components are connected
- Start the engine. Rev the engine to 3000 RPM
- Check that only a faint clicking sound is heard when the freewheel engages and disengages
- Quickly switch off the engine. Check that the generator rotates for longer than the engine.

NOTE: **If it is cold, the battery charge warning lamp may light shortly after start-up because the freewheel needs to rotate and warm up the bearing grease before it locks and engages the rotor shaft. If the warning lamp remains lit, it may be an indication that the freewheel has not locked the pulley to the rotor shaft.**

Checking the function of the freewheel on a removed generator (GEN)

- Rotate the pulley counter-clockwise and brake the pulley heavily. The freewheel must grip the rotor shaft when rotating counter-clockwise
- Stop the rotation by braking the pulley. When braking the pulley, the freewheel mechanism should release so that the rotor shaft continues to rotate.

Remedy as necessary.

  Read off the status of the L signal.

  The L signal between the governor and the central electronic module (CEM) is used both to pre-magnetize the generator (GEN) and to provide a signal to the central electronic module indicating that the generator (GEN) is not charging when the engine is running. For information about the L signal, see **DIAGNOSTIC FUNCTIONS** .

  When the connector for the L signal is disconnected at the generator (GEN) the value should read < 0.2 V with the ignition on. Disconnect the connector for the L signal from the generator (GEN). The value of the L signal must then change to > 0.8 V.

HINT: OnD5252Tengines the wiring for the L signal and DF signal are mounted in a common two pin connector. See the L and DF markings on the rear face of the generator (GEN).

NOTE: Diagnostic trouble codes (DTCs) may be stored in the central electronic module (CEM) when the L signal is disconnected. Erase any stored diagnostic trouble codes (DTCs) after fault-tracing.

NOTE: **Diagnostic trouble codes (DTCs) may be stored in the central electronic module (CEM) when the L signal is disconnected. Erase any stored diagnostic trouble codes (DTCs) after fault-tracing.**

FAULT-TRACING INFORMATION

Condition

Fig. 99: Identifying Generator Terminals
Courtesy of VOLVO CARS CORPORATION

The L signal between the governor and the central electronic module (CEM) is used both to pre-magnetize the generator (GEN) and to provide a signal to the central electronic module indicating that the generator (GEN) is not charging when the engine is running. When the generator (GEN) starts charging, the charge increases in stages for a short time. At the same time the load on the engine also increases in stages. The generator (GEN) will not charge the battery if the L signal is missing.

NOTE: **The generator (GEN) regulator can self magnetize the rotor and start charging in this way. This only happens at speeds in excess of approximately 2300 RPM. There is no charge engagement by stages with self magnetization, the generator operates at full charge immediately.**

Possible Source

- Contact resistance or oxidation in the connectors
- Open-circuit in the L signal cable between the generator (GEN) and the central electronic module (CEM), short-circuit to ground or voltage.

Fault symptom[s]

- The battery discharges

- The "Generator not charging" warning lamp does not light when the ignition is switched on
- The "Generator not charging" warning lamp is lit when the engine is running.

CHECKING THE STAND-BY CURRENT CONSUMPTION (2003-04)

CHECKING THE STAND-BY CURRENT CONSUMPTION

The generator (GEN) has been designed to supply the car with sufficient current for normal electrical loads when driving. The battery functions as a buffer for extreme consumption or driving conditions. When the engine is switched off, it is the battery that supplies the car with energy. Components or functions which consume energy when the ignition is switched off are items such as the engine cooling fan (FC), blower fan, lighting, control modules etc. The control modules in the car consume energy for up to 10 minutes after the ignition was switched off.

Check the stand-by current consumption. See **STANDBY CURRENT, MEASURING/FAULT-TRACING** .

Other information

- For general information about electrical consumption, see **ELECTRICAL CONSUMPTION, GENERAL**
- For information about the stand-by consumption of components, see **STAND-BY CURRENT, CONSUMPTION VALUE** .

Possible Source

- Great resistance in the starter circuit due to poor contact in connectors/transitions in the power supply side (B+).
- Great resistance in the starter circuit due to poor contact in connectors/transitions in the ground side (B-).
- Worn carbon brushes or too low pressure in the brush springs
- Large resistance because of a dirty commutator
- Short-circuit in the windings
- Defective bearing which makes the rotor drag against the pole pieces.
- Poor battery.

Fault symptom[s]

- Low rotation speed in the starter motor.

CHECKING THE STARTER MOTOR RELAY (2003-04)

CHECKING THE STARTER MOTOR RELAY

CHECKING THE POWER SECTION OF THE STARTER RELAY

NOTE: The test assumes that the battery is fault free, and that no relevant diagnostic trouble codes (DTCs) for the symptom are stored.

The signal chain to the starter motor can be checked quickly by short-circuiting the relay connections to the starter motor.

Move the gear selector to position P or N. Parking brake applied.

WARNING: The starter motor should operate when there is a short-circuit. Be very careful.

CAUTION: Use two cables with suitable cable terminal when short-circuiting so that the spark does not damage the relay socket.

Remove the starter motor relay and short-circuit the relay socket #3(30) with #5(87), that is, the relay circuit.

NOTE: Do not bridge directly in the relay base or the connections in the base may be damaged.

If the starter motor now operates there is no fault in the power section of the circuit.

Discharge yourself and tools to be used by holding the tool's metal part and touching a body part on the car just before starting to work.

- It is possible to deduce whether the fault is in the wiring or in the relay by connecting a electrician's screwdriver over the relay socket coil.
- Move the gear selector to position P or N. Parking brake applied.

  Connect a test probe between relay connection #1(86) and #2(85) on the relay socket. Turn the ignition to start position (ignition position III) and observe the light.

  If the electrician's screwdriver lights, replace the relay.

  If the test probe is not lit, check the cable between the ignition's 50-feed #7 and relay socket #1 (86). Also check the cable between the relay socket #2 (85) and central electronic module (CEM) #A3.

  Check the central electronic module (CEM) connector. Check for contact resistance and oxidation.

INSPECT TERMINALS VISUALLY

Fig. 1: Checking Contact Resistance & Oxidation
Courtesy of VOLVO CARS CORPORATION

NOTE: **When checking the engine control module (ECM), do not remove the control module from the car before the main relay has interrupted the power supply. This may take up to 4 minutes after the ignition has been switched off and the engine cooling fan (FC) has stopped running.**

Inspect the terminals visually when checking, or taking readings from, opened connectors.

Checks:

- Check for oxidation. This can cause poor connections in the terminals
- Check for damage to pins and terminals. Check that they are properly inserted into the connector. Check that the cable is properly connected to the pin or terminal. Check pins and terminals particularly carefully
- Using a loose male connector, test to, see if the female connector provides a good contact and that the pin remains in place when the male connector is pulled lightly
- Shake the cable lightly and pull on connectors during measurement to locate damage.

OPEN-CIRCUIT

Fig. 2: Checking For Open Circuit
Courtesy of VOLVO CARS CORPORATION

CAUTION: Avoid touching control module connector pins and corresponding cable harness connectors. There is a risk of electrostatic discharge, which could damage the control module. Relieve any charge on yourself and the tools to be used by holding the metal part of the tool and touching part of the body just before starting work.

An open-circuit in a cable will be indicated by the loss of a function (or functions).

Chafed and broken leads are common causes of faults.

Checks:

- Disconnect the connectors at both ends of the cable.

Check the cables visually according to **INSPECT TERMINALS VISUALLY**.

Connect an ohmmeter between the ends of the cable.

The ohmmeter should read approximately 0 ohms if there is no open-circuit in the cable.

NOTE: **When taking readings from the female connector it is important to position a replacement part between the female connector and the measuring instrument. The replacement part consists of a piece of cable with a cable terminal at one end. Never insert an object into the female connector. There is a risk of damaging the female connector.**

Shake the cable lightly and pull on connectors during measurement to locate the damage.

If the reading is not correct. Replace the cable and/or continue according to **CONTACT RESISTANCE AND OXIDATION**.

Fig. 3: Identifying Control Module Installation
Courtesy of VOLVO CARS CORPORATION

Always check the control module and control module box connectors to ensure that their pins and sockets are not bent or damaged, this may cause faults.

Check pins and terminals particularly carefully.

SHORT-CIRCUIT TO GROUND

Fig. 4: Checking For Short Circuit To Ground
Courtesy of VOLVO CARS CORPORATION

CAUTION: Avoid touching control module connector pins and corresponding cable harness connectors. There is a risk of electrostatic discharge, which could damage the control module. Relieve any charge on yourself and the tools to be used by holding the metal part of the tool and touching part of the body just before starting work.

A short-circuit between a live cable and ground is often indicated by the loss of a function or a fuse blowing when a current is passed through the cable.

Checks:

- Check the cables visually according to **INSPECT TERMINALS VISUALLY**.

  Activate all switches and sensors in the circuit. Check whether the fuse blows

- Disconnect the connectors in the circuit to ensure that they do not affect readings.

Connect an ohmmeter between cable and ground.

The ohmmeter should read infinite resistance if no components are connected.

NOTE: **When taking readings from the female connector it is important to position a replacement part between the female connector and the measuring instrument. The replacement part consists of a piece of cable with a cable terminal at one end. Never insert an object into the female connector. There is a risk of damaging the female connector.**

Shake the cable lightly and pull on connectors during measurement to locate the damage.

If the reading is not correct, replace the cable and/or continue according to **CONTACT RESISTANCE AND OXIDATION**.

SHORT-CIRCUIT TO SUPPLY VOLTAGE

Fig. 5: Checking For Short Circuit
Courtesy of VOLVO CARS CORPORATION

CAUTION: **Avoid touching control module connector pins and corresponding cable harness connectors. There is a risk of electrostatic discharge, which could damage the control module. Relieve any charge on yourself and the tools to be used by holding the metal part of the tool and touching part of the body just before starting work.**

A short-circuit between a cable and supply voltage is often indicated by the loss of a function or a fuse blowing

when a current is passed through the cable.

Checks:

- Check the cables visually according to **INSPECT TERMINALS VISUALLY**.

  Use a voltmeter to take readings at various points in the circuit while operating switches and sensors.

The voltmeter reading depends on the circuit being tested and the positions of switches and sensors.

Use an ohmmeter between the suspect cables to detect short-circuits between them.

The ohmmeter should read infinite resistance between cables not connected to each other in the circuit.

NOTE: **When taking readings from the female connector it is important to position a replacement part between the female connector and the measuring instrument. The replacement part consists of a piece of cable with a cable terminal at one end. Never insert an object into the female connector. There is a risk of damaging the female connector.**

Shake the cable lightly and pull on connectors during measurement to locate the damage.

If the reading is not correct. Replace the cable and/or continue according to **CONTACT RESISTANCE AND OXIDATION**.

LOOSE CONNECTIONS (TERMINALS)

Fig. 6: Identifying Terminal Inspection
Courtesy of VOLVO CARS CORPORATION

Loose connections in terminals may be caused by oxidation of the pins and sockets, or by a faulty connection of a cable to its cable terminal.

Loose connections produce the same faults as an intermittent open-circuit in a cable.

Checks:

- Inspect terminals visually according to **INSPECT TERMINALS VISUALLY**.

  Continue according to **CONTACT RESISTANCE AND OXIDATION**.

CONTACT RESISTANCE AND OXIDATION

Fig. 7: Identifying Terminal Inspection
Courtesy of VOLVO CARS CORPORATION

CAUTION: Avoid touching control module connector pins and corresponding cable harness connectors. There is a risk of electrostatic discharge, which could damage the control module. Relieve any charge on yourself and the tools to be used by holding the metal part of the tool and touching part of the body just before starting work.

The resistance in switches, cables and terminals should be 0 ohms. There is sometimes some resistance in connections due to oxidation.

If resistance is too great there will be function problems. The magnitude of the resistance before it causes a malfunction depends on the circuit load. A guideline would be a few ohms.

NOTE: When taking readings from the female connector it is important to position a replacement part between the female connector and the measuring instrument. The replacement part consists of a piece of cable with a cable terminal at one end. Never insert an object into the female connector. There is a risk of damaging the female connector.

Cleaning female socket terminals and male pin terminals

NOTE: **Do not apply rust solvent spray or grease to the catalyst monitor sensor or instrument cluster connectors.**

- Ignition off
- Disconnect the battery negative terminal
- Use compressed air to clean the disconnected connector
- Apply rust solvent spray 1161422 to the disconnected connectors
- Blow clean using compressed air.

Greasing female terminals

Fig. 9: Identifying Grease Pressed Into Terminals
Courtesy of VOLVO CARS CORPORATION

NOTE: Do not fill the protective cover with grease.

- Press grease, P/N 1161417-9, into the terminals directly from the tube
- Check that all the cavities in the connectors are filled
- Use a loose male pin to ensure that contact in sockets is good. The pin should remain in position when pulled gently.

INTERMITTENT FAULT-TRACING

The reason the car is in the workshop is because the customer has experienced abnormalities with the car. The symptoms experienced by the customer does not always coincide with a permanent fault. The fault might not occur when the customer arrives at the workshop but occurs on a single occasion.

In order to deduce the fault type is important to check the symptoms reported by the customer:

- How does the car behave? Is the car difficult to start, are the gears hard to shift, does the tachometer flicker etc.
- What are the circumstances when the fault occurs? under heavy load, is it dependent on the weather, outside temperature, on uneven roads, when making sharp turns, only when the engine is cold, under hard braking etc.

It is important to interview the customer about the surrounding circumstances in the event of a fault.

It may be an advantage to simulate the driving conditions for when the symptom occurs and carry out an analysis and deduce the fault. By deducing the fault, the symptom can be remedied so that the fault does not recur.

When a diagnostic trouble code (DTC) has been stored the freeze frames are also stored. These can be used to recreate the driving conditions for the diagnostic trouble code (DTC).

Tools:

- Reading off freeze frames, read off the freeze frame data for the relevant diagnostic trouble code (DTC)
- Status identifier, read off the status of the selected diagnostic trouble code (DTC)
- The counter indicates, amongst other things, how many fault free cycles have been carried out since the diagnostic trouble code (DTC) was stored.

INTERMITTENT ELECTRICAL FAULT

An intermittent electrical fault can be caused by faults in the wiring, components or connectors.

Possible fault causes for intermittent electrical faults are:

- Damaged terminal pins in the connector
- Loose connections in the connectors
- Poor ground connection (oxidation)
- Moisture, poor connections in the connector
- Defects, cracking, damage on the components
- Strong magnetic or other interference that has affected the control modules.

INTERMITTENT FUNCTIONAL FAULTS

Intermittent functional faults could be caused by mechanical defects in the components.

- Cracked or blocked hoses
- Incorrect oils, fluids
- Incorrect fuel
- Sticking mechanical components.

INTERMITTENT INTERNAL FAULTS

Intermittent internal faults could be due to:

- Electromechanical interference
- Power supply too low
- Oxidized ground terminal for the control module
- Defective internal components.

INTERMITTENT COMMUNICATION PROBLEMS

Intermittent communication problems could be due to:

- Electromechanical interference
- Oxidation/loose connections in the connectors
- Defective signal cables.

SIMULATING FAULT CAUSES

A large amount of input data is a required to recreate and simulate fault occurring circumstances.

Certain cases can be difficult to recreate. High speed driving and stalling to achieve high loads is not recommended.

In order to achieve high loads accelerate hard in quick succession a number of time instead.

Cases that are possible to simulate:

- high load
- moisture
- heat
- cold
- loose connections.

High load

High load can be simulated by accelerating hard repeatedly.

Moisture

Moisture can be simulated by spraying water on the suspected faulty component or connector using a spray bottle or hose.

Heat

Heat can be simulated by using a hot air gun or similar to heat up a suspected faulty component or connector.

In order to achieve a high engine temperature allow the engine to idle at a high load with the hood down to prevent air flowing through the engine compartment. Run the engine in hot conditions. Read off the engine coolant temperature (ECT) using VIDA, the temperature gauge in the combined instrument panel is progressive.

Cold

Cold can be simulated by cooling down the suspected faulty component or connector using a freeze spray.

Loose connections

Loose connections can be simulated by twisting and shaking the connector whilst the function is activated.

CARS EQUIPPED WITH SRS/SIPS (AIRBAG)

WARNING: **Extra care must be taken when working on cars equipped with SRS/SIPS air bags. This is important to prevent:**

1. Personal injury

2. Damage to or malfunction of the SRS/SIPS system.

Work on the SRS/SIPS systems or related components must always be carried out by an authorized Volvo workshop.

Is the car equipped with SRS (supplemental restraint system)?

Cars equipped with a driver's airbag have the letters "SRS" imprinted on the center panel of the steering wheel. Cars equipped with driver's and passenger airbags are marked with "SRS" on both the steering wheel center panel and also on the dashboard close to the airbag.

If the car is equipped with SIPS (side impact protection system) a "SIPS" decal is marked on both the front seats.

Cars equipped with inflatable curtains have the marking "SRS" on one of the panels along the posts on the inside of the car.

Cars equipped with SRS (supplemental restraint system) also have an "SRS" decal on the front windscreen.

WARNING: **The air bag inflation areas must not be obstructed. Never place any objects, such as upholstery or accessories, within these areas. The panels must be able to open in the correct manner at the right time, otherwise there is an increased risk of personal injury in the event of a collision.**

Do not damage the SRS wiring.

Do not trap, chafe, pierce or damage the SRS wiring. SRS wiring has orange casing and/or is plaited.

Steering and front suspension

The contact reel in the SRS system can easily be damaged when working on the steering wheel, steering shaft or steering gear. Refer to the SRS (supplemental restraint system) Service Manual or service instructions in VIDA (Volvo Scan Tool) for information on carrying out such work. This is to prevent damage.

SRS warning lamp

If the SRS warning lamp lights after repairs have been carried out, take the car to an authorized Volvo workshop.

SUPPLEMENTAL RESTRAINT SYSTEM MODULE, SRS

XC90

The supplemental restraint system module (SRS) is located on the tunnel under the center console, in front of the parking brake.

ALARM (2003)

ALARM

SYMPTOM AND FUNCTION DESCRIPTION

All alarm inputs are continuously monitored when the alarm is activated. The alarm is activated by pressing the button. A long flashing signal, from the vehicle's direction indicators, confirms that the alarm is activated and that the doors are locked. The alarm LED will start to flash directly after the system has been activated.

The alarm should trip when:

- Door, bonnet or boot lid are opened.
- The ignition switch is turned with a non-approved key or subjected to force.
- Movement detected in the passenger compartment (only applies if the vehicle is equipped with a movement sensor).
- The vehicle is lifted or towed away (only applies if the vehicle is equipped with a level movement sensor).
- Someone attempts to disconnect the siren or battery.

The siren is used as the sound source for the alarm function. The siren includes an internal battery which is charged when the lights are on. The climate affects the life of the battery. The battery cannot be replaced as a single component. Consequently the siren should be replaced at regular intervals.

HINT: For more information, see OTHER ELECTRICAL EQUIPMENT - DESIGN AND FUNCTION .

Verification

Check the different alarm system functions as follows:

NOTE: The alarm must not trip during testing. If the alarm goes off it should be possible to deactivate using the remote key's unlock button or by putting the remote key in the starter switch. A signal confirming alarm deactivation must be given by the direction indicators (two short flashes).

Testing the movement sensor

- Sit in the vehicle.
- Deactivate the movement sensor, then activate the alarm.
- Wait 30 seconds. Without moving.
- Test the movement senor in the passenger compartment by moving.

Testing the function of the indicator LED

- Check the LED status before and after alarm activation and with the ignition switched on.

Interpret LED indication flashing as follows:

- Unlit LED, indicates that the alarm is deactivated
- The LED flashes rapidly, after the alarm has been deactivated, up until the ignition is switched on. Indicates that the alarm has been tripped.
- The LED flashes once per second after the vehicle's direction indicators have produced one long flashing signal. Flashing indicates that the alarm is activated.

ALARM (2004-12)

ALARM

SYMPTOM AND FUNCTION DESCRIPTION

All alarm inputs are continuously monitored when the alarm is activated. The alarm is activated by pressing the button. A long flashing signal, from the vehicle's direction indicators, confirms that the alarm is activated and that the doors are locked. - Movement detected in the passenger compartment (only applies if the vehicle is equipped with a movement sensor).
- The vehicle is lifted or towed away (only applies if the vehicle is equipped with a level movement sensor).
- Someone attempts to disconnect the siren or battery.
- The panic function is activated via the remote key.

The siren is used as the sound source for the alarm function. The siren includes an internal battery which is charged when the lights are on. The climate affects the life of the battery. The battery cannot be replaced as a single component. Consequently the siren should be replaced at regular intervals.

HINT: For more information, see OTHER ELECTRICAL EQUIPMENT - DESIGN AND FUNCTION .

Verification

Check the different alarm system functions as follows:

NOTE: The alarm shall trip during each test, a siren shall sound and all direction indicators flash. It should be possible to deactivate the alarm using the remote

key's unlock button or by inserting the remote key in the starter switch. A signal confirming alarm deactivation must be given by the direction indicators (two short flashes).

Testing the doors

- Open all windows.
- Deactivate the movement sensor, then activate the alarm.
- Wait 30 seconds.
- Open one of the doors by using the handle on the inside of the door.

Testing the hood

- Sit in the vehicle.
- Deactivate the movement sensor, then activate the alarm.
- Wait 30 seconds.
- Open the bonnet with the handle below the instrument panel.

Test of automatic activation (market dependent)

- Activate the alarm.
- Wait 30 seconds.
- Deactivate the alarm with the remote key. Do not open the doors or hoods.
- Wait two minutes. The vehicle shall automatically activate the alarm and lock the doors.

FRONT/REAR PARKING ASSISTANCE (2003-04)

FRONT/REAR PARKING ASSISTANCE

SYMPTOM AND FUNCTION DESCRIPTION

The parking assistance system is activated automatically when the vehicle starts. An LED illuminates in the button for park assist when the system is active.

- Parking assistance is active at speeds below 15 km/h. At higher speeds, the system deactivates. When the speed drops below 10 km/h, the system is activated again.
- The closer the vehicle gets to the object behind, the more frequent the signal occurs. At a distance of approx. 30 cm, the tone should be constant.

Rear parking assistance

- Parking assistance in reverse activates when reverse is engaged.
- The measurement range behind the vehicle is approximately 1.5 m.

- A message is shown in the text display, in the driver information module, in case of many malfunctions in the parking assistance system.
    - Horn.
    - Wet tires on asphalt.
    - Pneumatic brakes.
    - Exhaust pipe on motor bike.
- Snow and ice on the sensors can impair the function.
    - Horn.
    - Wet tires on asphalt.
    - Pneumatic brakes.
    - Exhaust pipe on motor bike.
- If a trailer is connected or a bicycle holder is on the tow hitch, the system must be switched off.
    - Horn.
    - Wet tires on asphalt.
    - Pneumatic brakes.
    - Exhaust pipe on motor bike.
- Under certain circumstances the park assist system may give false warning signals, which are caused by external sound sources, which produce the same ultrasound frequencies that the system works with. This does not indicate a fault in the system. Examples of such sources are:
    - Horn.
    - Wet tires on asphalt.
    - Pneumatic brakes.
    - Exhaust pipe on motor bike.

Verification

Access to the vehicle is necessary for the following checks.

- Ignition on or start the engine.
- Engage reverse gear.

Does text appear in the audio display when reverse gear is selected?

Is sound emitted from the loudspeakers, if there is an object behind the vehicle?

Test by placing an object or having a person stand behind the vehicle. Move the object/person both closer to and further away from the vehicle and check that the sound frequency increases the closer one gets. At a distance of approx. 30 cm, the tone should be constant.

On left-hand drive vehicles, the sound is emitted from the right-hand rear loudspeakers.

Test this in the same way, by positioning a person or object in front of the vehicle. Sound should be heard from the loudspeaker.

HEADLAMP WASHER (2004)

HEADLAMP WASHER

SYMPTOM AND FUNCTION DESCRIPTION

This function is an option on some markets. Headlamp wipers are on certain models.

Headlamp washing is activated at the same time as windscreen wiper washing is activated. Cleaning is started by moving the stalk towards the steering wheel. The wipers operate for as long as washing is activated.

The headlamp wipers are not activated when only the windscreen wipers are activated but when windscreen washing is activated.

High pressure washing of the headlamps requires large amounts of washer fluid. To save on the amount of washer fluid, the washer is only activated every fifth time within a two minute period.

If the washer fluid level remains low, the supply of washer fluid to the headlamps is cut off. Headlamp washing will not occur when the washer fluid level is low.

Verification

- Switch on the ignition and check that no message regarding low washer fluid appears in the combined instrument panel.

  Check that the high pressure washer, and any wipers, activate for the headlamps when the windscreen washer is activated by moving the control stalk on the steering column.

When headlamp washing has occurred once, it will not occur again until 10 minutes have passed.

WINDSHIELD WIPERS - RAIN SENSOR (2003-04)

WINDSCREEN WIPERS - RAIN SENSOR

SYMPTOM AND FUNCTION DESCRIPTION

The rain sensor senses the amount of water on the windscreen and can then activate and control the speed of the wipers automatically to obtain a good view. The rain sensor is in front of rear view mirror on the inside of the windscreen.

To activate the rain sensor the key must be in ignition position I or II, and the windscreen wipers must be switched off. The stalk for the windscreen wipers must always be in position **0** .

The sensor is then activated by pressing the small button on the stalk. An LED illuminates as a confirmation that the function has been activated.

There are two ways of activating the rain sensor:

- Press the small button on the stalk again so that the LED goes out.
- Activate one of the other functions for the windscreen wipers by moving the stalk downwards.

The rain sensor function switches off automatically when the key is removed from the ignition or five minutes after the ignition has been switched off if the key has not been removed.

If there is a fault with the rain sensor during the time the function is active, intermittent wiping at high speed is selected.

If the fault occurs whilst the function is not active, intermittent wiping will be activated the next time the rain sensor function is attempted to be activated. But then only with a fixed interval and no change depending on the amount of precipitation.

CAUTION: Remember that the rain sensor function must be off during automatic washing. The windscreen wipers can otherwise start and become damaged.

Verification

- Switch on the ignition and ensure that the stalk for the windscreen wipers is in position **0** .

- Press the button for the rain sensor and check that the LED in the button illuminates when the function is activated.
- Check that the windscreen wipers start when water hits the windscreen in front of the rain sensor.
- Check that the rain sensor function disengages by moving the stalk downwards to another wiper program. The LED on the button must go out.

WINDSHIELD WASHER (2003-12)

WINDSHIELD WASHER

SYMPTOM AND FUNCTION DESCRIPTION

Windscreen cleaning is started by moving the stalk towards the steering wheel.

The wipers operate for as long as washing is activated.

The rear washer is operated by moving the right-hand control stalk on the steering column away from the steering wheel. The wipers operate for as long as washing is activated.

The windscreen must be properly wet when the wipers operate, therefore, generous amounts of washer fluid should be used when cleaning.

Verification

- Switch on the ignition and check that no message regarding low washer fluid appears in the combined instrument panel.

  The capacity of the washer fluid reservoir is 4.5 liters and a message regarding low level appears when the volume in the reservoir is below 1 liter.

- Check that washing occurs on the windscreen when the right-hand control stalk is moved towards the steering wheel and that the windscreen wipers run for as long as washing is activated.
- Check that washing occurs on the rear windscreen when the right-hand control stalk is moved away from on the steering column and that the wipers run for as long as washing is activated.

WINDSHIELD WIPER (2003-04)

WINDSHIELD WIPER

SYMPTOM AND FUNCTION DESCRIPTION

The windscreen wipers are switched off as long as the right-hand stalk is in position **0** . The windscreen wipers are operated using the control stalk, which has four different positions:

- Intermittent wiping.

NOTE: This function is replaced by the rain sensor if the vehicle is equipped with one.

- Single sweep.
- Normal speed.
- High speed.

Intermittent wiping.

The time between the sweeps for intermittent wiping can be adjusted using the collar on the stalk. Turning the collar clockwise (upwards) increases the frequency of the wiper strokes.

Turning the collar anticlockwise (downwards) decreases the frequency of the wiper strokes.

Single sweep.

If the right-hand stalk is moved up, the wipers will only make one sweep.

Normal speed.

The windscreen wipers sweep at normal speed.

High speed.

The windscreen wipers sweep at high speed.

A signal tells the vehicle when the windscreen wipers are in the "parked position" in order to stop the wipers in the correct position.

The control for the rear windscreen wipers is on the end of the right-hand stalk. The rear wipers are operated via a button, which has two positions.

Upwards

- Rear windscreen intermittent wiping.

Downwards

- Normal speed of rear windscreen wipers.

The rear windscreen wiper (intermittent wiping) is also normally activated if the windscreen wipers are on and reverse gear is engaged. If the rear wiper is already engaged at normal speed when reverse gear is engaged, the engaged function does not change. The function can be reprogrammed so that the rear windscreen wiper is not activated when reverse gear is engaged and the windscreen wipers are on.

Verification

Access to the vehicle is necessary for the following checks.

- Activate ignition position II.
  - Intermittent wiping.
  - Single sweep.
  - Normal speed.
  - High speed.
- Check that the different positions of the windscreen wipers work properly.
  - Intermittent wiping.
  - Single sweep.
  - Normal speed.

- Check that the interval reduces respectively increases if the collar on the control stalk is turned clockwise respectively anticlockwise.
- Check that intermittent wiping on the rear windscreen starts when the button on the end of the control stalk is set to the "upward" position.
- Check that wiping at normal speed starts when the button on the end of the control stalk is set to the "downwards" position.
- Check that rear windscreen wiping starts when reverse gear is engaged and the windscreen wiper is active (as long as the function has not been reprogrammed).

ELECTRICAL

ELECTRICAL

CENTRAL ELECTRONIC MODULE (CEM), INFORMATION ABOUT INCORRECT REPLACEMENT

When analyzing replaced central electronic modules (CEM), it has become evident that many replacements have been carried out incorrectly. In order to identify the main cause for certain electrical fault symptoms more easily, this document describes the role of the central electronic module (CEM) in the vehicle and the CAN network.

This service information is also intended to clear up misunderstandings and, in the final analysis, to reduce the number of incorrect replacements of the central electronic module (CEM).

NOTE: **The central electronic module (CEM) contains vehicle-specific information that cannot be deleted after programming and cannot be used in another vehicle. For this reason, the control module must not be programmed for a vehicle for the purpose of fault-tracing. Do not condemn the central electronic module (CEM) in advance.**

Common misunderstandings

- CAN-related faults

  "Do not shoot the messenger". Although the central electronic module (CEM) monitors CAN communication and verifies that all control modules are in the system, the control module is not responsible for all CAN activity. When CAN-related diagnostic trouble codes (DTCs) are present in the central electronic module (CEM), the control module is often wrongly thought to be defective.

  The central electronic module (CEM) can identify faults in other control modules as well as in wiring. When the CAN bus is active, the control module checks specific signals from other control modules. The diagnostic trouble codes (DTCs) CEM-1A5X-1A6X indicate that the central electronic module (CEM) was unable to receive the anticipated signals from other control modules. For more information:**INFORMATION ABOUT THE CAN NETWORK, STRUCTURE AND FUNCTION**

  Diagnostic trouble codes (DTCs) CEM-DF03-DF16 indicate short-circuits between the CAN cables (green or white) to battery voltage or ground. This does not mean that the central electronic module (CEM) is damaged, but that the control module has detected a fault somewhere in the CAN network

  1. The first central electronic module (CEM) was defective
  2. The second central electronic module (CEM) is also defective, but with a different fault.
- Discharged battery

When fault-tracing a vehicle with battery problems, control modules with a constant power supply must be checked carefully. For example, is any lamp lit when it should be off? Is the power circuit for the blower fan still drawing current after the ignition key has been removed? Are the heater pads for the door mirrors constantly switched on? Is any relay constantly engaged? These are only a few examples. The wiring diagram of the relevant car must be used for further fault causes

1. The first central electronic module (CEM) was defective
2. The second central electronic module (CEM) is also defective, but with a different fault.

- Downloading software

  Since version 2000C, VIDA (Volvo scan tool) has a slightly different procedure for downloading software. This procedure must be followed when downloading software in, or replacing, the central electronic module (CEM). Incorrect downloading of software does not damage the control module, but can be difficult to rectify

  1. The first central electronic module (CEM) was defective
  2. The second central electronic module (CEM) is also defective, but with a different fault.

- Problems with the Immobilizer

  Immobilizer problems are rarely caused by faulty hardware in the central electronic module (CEM)

  1. The first central electronic module (CEM) was defective
  2. The second central electronic module (CEM) is also defective, but with a different fault.

- Incorrect relay activation

  Some central electronic modules (CEM) have been replaced mistakenly when all that was damaged was a system relay. Relays are very simple to replace and test in other positions or in another car. The control module is often incorrectly diagnosed due to a faulty system relay. The faulty relay may have been moved to a different location after the central electronic module (CEM) has been replaced.

  This gives the incorrect impression that:

  1. The first central electronic module (CEM) was defective
  2. The second central electronic module (CEM) is also defective, but with a different fault.

The relays that control the power supply from the central electronic module (CEM) to other control modules should permit simple fault-tracing. For example, if the diagnostic trouble codes (DTCs) CEM-1A54, (communication with the power seat module (PSM)), CEM-1A55 (communication with the climate control module (CCM)) and CEM-1A56 (communication with the driver information module (DIM)) are stored in the central electronic module (CEM), it is important to check the X-supply relay.

A few tips

- The monitoring function for the central electronic module (CEM) in VIDA (Volvo scan tool) is a good tool for determining whether a relay is engaged or whether an input is high or low. This function, alongside readings using the breakout box, solves many problems related to the function of the control

module. Note that only the coil in the relay for the control module is diagnosed, not the relay output

- When CAN-related diagnostic trouble codes (DTCs) are fault-traced, use the relevant "Data communication" pages in the wiring diagrams for the car model in question. These pages contain important information about how the control modules are connected in relation to each other. Parallel or in series
- The central electronic module (CEM) contains PIN codes for the immobilizer function but has nothing to do with the codes for remote controls or memories for power seats and mirrors with memory. (Remote control codes are stored in the upper electronic module (UEM), the power seats are controlled by the power seat module (PSM) and the mirror memories are in the driver's door module (DDM) and the passenger door module (PDM))
- The start relay that is activated by the central electronic module (CEM) has 0 V from the output from the control module in both activated and not activated modes. Do not rule out fault causes based solely on voltage readings. Check whether the relay is clicking or use a test lamp if necessary. The 0 V that is "supplied" by the central electronic module (CEM) in deactivated mode does not engage the relay coil
- The central electronic module (CEM) monitors CAN H (white cable) and CAN L (green cable). This does NOT mean that all CAN problems are related to this control module. The likelihood of the central electronic module (CEM) causing an E001 diagnostic trouble code (DTC) is no greater than this being caused by some other control module. When fault-tracing CAN-related faults in the central electronic module (CEM) or other control modules, measure the resistance in the CAN bus. Check behind the radio for short-circuited wiring, check the CAN cables for the supplemental restraint system module (SRS), the transmission control module (TCM) and the engine control module (ECM) as well as the connectors

NOTE: **Do not use an electrician's screwdriver or other tool when checking the connectors, as this may damage the connector. Male terminal P/N 9441394 (Female terminal P/N 9442486) can be used to check the affected connectors.**

NOTE: **If diagnostic trouble code (DTC) E001 is permanently stored in a control module and the wiring is OK, a good tip is to cut the power to the control modules that have stored E001 (except for the central electronic module (CEM)) and check whether the code disappears. Then restore the power supply to one control module at a time until the code recurs. If it is possible to communicate with the car in ignition positions 0 and 1 but not in position 2, look for a control module that is powered via the ignition switch (+15) to find the defective control module.**

-
-
- In order to isolate the OBD2 connector from the rest of the CAN network in the car, the central electronic module (CEM) contains four diagnostic relays. This means that the control module "opens" communication with both the low speed and specification networks via hardware. The command for opening communication is given over the communication cable from VIDA (Volvo scan tool) to the central electronic module (CEM).

  This means that if VIDA (Volvo scan tool) can communicate with at least one control module on the low speed network and one control module on the high speed network, the relays are working properly. Defective communication cable communication between VIDA and the central electronic module (CEM)

means that both networks are inaccessible. Where there is no communication between VIDA and the car, and the car is functioning properly, check the cable to scan tool.

- The central electronic module (CEM) is involved in the alarm function, but so are other control modules. For cars after model year 01, VIDA (Volvo scan tool) can be used to check the cause of the alarm. Verify correct function of door locks, the passenger door module (PDM), the driver's door module (DDM) and the upper electronic module (UEM) using the monitoring function in VIDA, for example

NOTE: **There is a considerable difference between "there are no diagnostic trouble codes (DTCs) in a control module" and "the control module is not reporting any diagnostic trouble codes (DTCs)". When diagnostic trouble codes (DTCs) are read from all control modules and there is a permanent CAN problem, the information can be misinterpreted. If a control module is not listed, it does not necessarily mean that the control module does not contain diagnostic trouble codes (DTCs). It may also mean that the control module is not responding.**

-
- The central electronic module (CEM) only sends the temperature of a serial cable to the seat heating module (SHM). If the serial cable reports good voltage values, it is unlikely that the central electronic module (CEM) is the cause of any problems with seat heating.

CHECKING WIRING AND TERMINALS. INTERMITTENT FAULTS

INSPECT TERMINALS VISUALLY

Fig. 1: Checking Contact Resistance & Oxidation
Courtesy of VOLVO CARS CORPORATION

NOTE: **When checking the engine control module (ECM), do not remove the control module from the car before the main relay has interrupted the power supply. This may take up to 4 minutes after the ignition has been switched off and the engine cooling fan (FC) has stopped running.**

Inspect the terminals visually when checking, or taking readings from, opened connectors.

Checks:

- Check for oxidation. This can cause poor connections in the terminals
- Check for damage to pins and terminals. Check that they are properly inserted into the connector. Check that the cable is properly connected to the pin or terminal. Check pins and terminals particularly carefully
- Using a loose male connector, test to, see if the female connector provides a good contact and that the pin remains in place when the male connector is pulled lightly
- Shake the cable lightly and pull on connectors during measurement to locate damage.

OPEN-CIRCUIT, INTERMITTENT FAULTS

Fig. 2: Checking For Open Circuit
Courtesy of VOLVO CARS CORPORATION

An open-circuit in a cable will be indicated by the loss of a function (or functions).

Chafed and broken leads are common causes of faults.

Checks:

- Disconnect the connectors at both ends of the cable.

Check the cables visually according to **INSPECT TERMINALS VISUALLY**.

Connect an ohmmeter between the ends of the cable.

The ohmmeter should read approximately 0ohms if there is no open-circuit in the cable.

Shake the cable lightly and pull on connectors during measurement to locate the damage.

If the reading is not correct. Replace the cable and / or continue according to **CONTACT RESISTANCE AND OXIDATION**.

Fig. 3: Identifying Control Module Installation
Courtesy of VOLVO CARS CORPORATION

Always check the control module and control module box connectors to ensure that their pins and sockets are not bent or damaged, this may cause faults.

Check pins and terminals particularly carefully.

SHORT-CIRCUIT TO GROUND, INTERMITTENT FAULTS

Fig. 4: Checking For Short Circuit To Ground
Courtesy of VOLVO CARS CORPORATION

A short-circuit between a live cable and ground is often indicated by the loss of a function or a fuse blowing when a current is passed through the cable.

Checks:

- Check the cables visually according to **INSPECT TERMINALS VISUALLY**.

  Activate all switches and sensors in the circuit. Check whether the fuse blows

- Disconnect the connectors in the circuit to ensure that they do not affect readings.

Connect an ohmmeter between cable and ground.

The ohmmeter should read infinite resistance if no components are connected.

Shake the cable lightly and pull on connectors during measurement to locate the damage.

If the reading is not correct, replace the cable and / or continue according to **CONTACT RESISTANCE AND OXIDATION**.

SHORT-CIRCUIT TO SUPPLY VOLTAGE, INTERMITTENT FAULTS

Fig. 5: Checking For Short Circuit
Courtesy of VOLVO CARS CORPORATION

A short-circuit between a cable and supply voltage is often indicated by the loss of a function or a fuse blowing when a current is passed through the cable.

Checks:

- Check the cables visually according to **INSPECT TERMINALS VISUALLY**.

  Use a voltmeter to take readings at various points in the circuit while operating switches and sensors.

The voltmeter reading depends on the circuit being tested and the positions of switches and sensors.

Use an ohmmeter between the suspect cables to detect short-circuits between them.

The ohmmeter should read infinite resistance between cables not connected to each other in the circuit.

Shake the cable lightly and pull on connectors during measurement to locate the damage.

If the reading is not correct. Replace the cable and / or continue according to **CONTACT RESISTANCE AND OXIDATION**.

LOOSE CONNECTIONS (TERMINALS)

Fig. 6: Identifying Terminal Inspection
Courtesy of VOLVO CARS CORPORATION

Loose connections in terminals may be caused by oxidation of the pins and sockets, or by a faulty connection of a cable to its cable terminal.

Loose connections produce the same faults as an intermittent open-circuit in a cable.

Checks:

- Inspect terminals visually according to **INSPECT TERMINALS VISUALLY**.

  Continue according to **CONTACT RESISTANCE AND OXIDATION**.

CONTACT RESISTANCE AND OXIDATION

Fig. 7: Identifying Terminal Inspection
Courtesy of VOLVO CARS CORPORATION

In theory, the resistance across contacts, leads and terminals should be 0 ohms. However, there is always some resistance due to terminal oxidation.

If resistance is too great there will be function problems. The magnitude of the resistance before it causes a malfunction depends on the circuit load. A guideline would be a few ohms.

Cleaning female socket terminals and male pin terminals

Fig. 8: Apply Rust Solvent Spray Or Grease To Connectors
Courtesy of VOLVO CARS CORPORATION

NOTE: **Do not apply rust solvent spray or grease to the catalyst monitor sensor or instrument cluster connectors.**

- Ignition off
- Disconnect the battery negative terminal
- Use compressed air to clean the disconnected connector
- Apply rust solvent spray 1161422 to the disconnected connectors
- Blow clean using compressed air.

Greasing female terminals

Fig. 9: Identifying Grease Pressed Into Terminals
Courtesy of VOLVO CARS CORPORATION

NOTE: Do not fill the protective cover with grease.

- Press grease, P/N 1161417-9, into the terminals directly from the tube
- Check that all the cavities in the connectors are filled
- Use a loose male pin to ensure that contact in sockets is good. The pin should remain in position when pulled gently.

CHECKING WIRING AND TERMINALS. PERMANENT FAULTS

CHECK TERMINALS VISUALLY

NOTE: **When checking the engine control module (ECM), do not remove the control module from the car before the main relay has interrupted the power supply. This may take up to 4 minutes after the ignition has been switched off and the engine cooling fan (FC) has stopped running.**

Inspect the terminals visually when checking, or taking readings from, opened connectors.

Checks:

- Check for oxidation. This can cause poor connections in the terminals
- Check for damage to pins and terminals. Check that they are properly inserted into the connector. Check that the cable is properly connected to the pin or terminal. Check pins and terminals particularly carefully
- Use a separate male terminal to check the female terminal. Check that they are secure: Pull on the pin.

OPEN-CIRCUIT, PERMANENT FAULTS

Fig. 12: Checking For Open Circuit

An open-circuit in a cable is indicated by a loss of one or more functions.

Chafed and broken cables or terminals that have come loose are common causes of faults in electrical systems.

- Disconnect the connectors at both ends of the cable.

Connect an ohmmeter between the ends of the cable.

The ohmmeter should read approximately 0 ohms if there is no open-circuit in the cable.

Checks:

- Use a voltmeter to take readings at various points in the circuit while operating switches and sensors.

Voltmeter readings will depend on which circuit is tested and the status of switches and sensors.

Use an ohmmeter between the suspect cables to detect short-circuits between them.

The ohmmeter should read infinite resistance between cables not connected to each other in the circuit.

Check pins and terminals particularly for this fault. See **CHECK TERMINALS VISUALLY**.

CONTACT RESISTANCE AND OXIDATION

In theory, the resistance across contacts, leads and terminals should be 0 ohms. However, there is always some resistance due to terminal oxidation.

If this resistance becomes too great the result will be a malfunction. The magnitude of the resistance before it causes a malfunction depends on the circuit load.

Checks:

- Check the cables visually according to **CHECK TERMINALS VISUALLY**.

CAN NETWORK

INFORMATION ABOUT THE CAN NETWORK, STRUCTURE AND FUNCTION

This document explains how the structure of the CAN network, its function and how the on-board diagnostic system works. It also explains the circumstances under which diagnostic trouble codes (DTCs) are stored, as well as containing a few tips on how to conduct fault-tracing on the CAN network. Faults in the CAN network are often complicated to fault-trace because it is a distributed system and because diagnostic trouble codes (DTCs) are stored under different circumstances in different control modules.

The information in this document should ideally be used as a basis for understanding how the CAN network works, diagnostics for the system and how to carry out fault-tracing. There is no guarantee that it will help you find a fault source for a specific problem immediately. This document should be viewed as a supplement to the normal training information and is suitable for mechanics who have completed and understood the content of the "Volvo Automotive Networks" course.

Diagnostic functions in the central electronic module (CEM)

The central electronic module (CEM) is the only control module that monitors the voltage levels in the control area network (CAN). Only this control module can store diagnostic trouble codes (DTCs) for short-circuits between the CAN cables and ground or supply voltage (e. g. DTC CEM-DF14). However, other control modules can store diagnostic trouble codes (DTCs) for causes based on a short-circuit (e. g. DIM-E003). This is a small, but very important difference.

NOTE: **The fact that the central electronic module (CEM) contains more diagnostics functions that other control modules does not mean that this control module is the cause of the fault. Do not replace the central electronic module (CEM) in the event of CAN-related faults unless an internal fault has been confirmed through fault-tracing.**

The central electronic module (CEM) also has functions for determining whether other control modules have failed. All control modules on the CAN network must transmit and receive information. More specifically, all other control modules in the controller area network (CAN) must receive information from the central electronic module (CEM), and the central electronic module (CEM) must receive information from all other control modules in the controller area network (CAN). If a control module does not receive information from the central electronic module (CEM) it will store diagnostic trouble code (DTC) XXX-E003. If the central electronic module (CEM) cannot receive information from a control module it will store diagnostic trouble code (DTC) CEM-1A51 to CEM- 1A66 depending on which control module the central electronic module (CEM) is not receiving information from. For example, the climate control module (CCM) will store diagnostic trouble code (DTC) CCM-E003 if it does not receive information from the central electronic module (CEM), and the central electronic module (CEM) will store diagnostic trouble code (DTC) CEM-1A55 if it does not receive any information from the climate control module (CCM).

If there is an open-circuit in the CAN network, diagnostic trouble codes (DTCs) will be stored in pairs, one in the central electronic module (CEM) and one in the relevant control module. Note that this may result in the central electronic module (CEM) storing so many diagnostic trouble codes (DTCs) that it reaches its maximum (10).

These diagnostic trouble codes (DTCs) are explained in detail under Diagnostic trouble codes (DTCs) CEM-1A51 to CEM-1A66.

Diagnostic trouble codes (DTCs) for faults in the CAN network

Diagnostic trouble codes (DTCs) CEM-DF03 to CEM-DF16

The central electronic module (CEM) is the only control module that can detect a short-circuit to ground or to voltage. This is done by measuring the voltage level on the CAN cables via an internal voltmeter in the central electronic module (CEM) and as a result the diagnostic trouble codes (DTCs) CEM-DF03 to CEM-DF16 can be stored.

NOTE: There are different codes for the high speed and low speed networks. DF03, DF04, DF05 and DF06 refer to the low speed network while DF13, DF14, DF15 and DF16 refer to the high speed network.

There is no defined function for detecting an open-circuit in the CAN cables, but a number of diagnostic trouble codes (DTCs) will be stored as a result of an open-circuit. Diagnostic trouble codes (DTCs) CEM-DF03 to CEM-DF16 are the strongest indication of a fault in the CAN network, although the diagnostic trouble codes (DTCs) cannot localize the fault. Due to the criteria that cause these codes to be stored, diagnostic trouble codes (DTCs) can also be stored if the car is driven in areas with strong magnetic fields.

The CAN cables are monitored continuously for faults of this type. It can take up to ten seconds from the time the fault occurs until the diagnostic trouble code (DTC) is stored. Diagnostic trouble codes (DTCs) CEM-DF03 to CEM-DF16 are stored when the voltage on one of the CAN cables is higher than 4.5 V or lower than 0.5 V. A typical scenario when these codes are stored is when one of the CAN cables has been clamped together with a ground lead or a power supply cable.

Diagnostic trouble codes (DTCs) CEM-1A51 to CEM-1A66

The central electronic module (CEM) expects to receive a signal from each control module on the network. The control module stores a diagnostic trouble code (DTC) for faults in the communication with a control module, or "node not alive", if there is no communication for more than ten seconds.

The diagnostic trouble codes (DTCs) are normally stored in the event of an open-circuit in the CAN cables, a short-circuit to voltage or ground, when the control module has no supply voltage or if other circumstances cause the control module to stop communicating with the central electronic module (CEM). Combinations of diagnostic trouble codes (DTCs) CEM-1A51 to CEM-1A66 are very useful for localizing a fault in the network. See the section "Multiple diagnostic trouble codes (DTCs) and extended diagnostics".

If the status of diagnostic trouble codes (DTCs) CEM-1A51 to CEM-1A66 is intermittent, always check that communication is possible between all control modules when carrying out repairs. Then check the power supply

and ground for the affected control modules. The control module will not store a diagnostic trouble code (DTC) if it was without power when the fault occurred. The central electronic module (CEM) on the other hand will store diagnostic trouble code (DTC) CEM-1A5X or CEM-1A6X even if the control module has no power supply or is experiencing other CAN communication problems.

Diagnostic trouble code (DTC) XXX-E003 stored in control modules other than the central electronic module (CEM)

Diagnostic trouble code (DTC) XXX-E003 is stored when an incorrect CAN configuration ID is received from a control module within 5 seconds of start up. This means that the control module cannot receive the data message with the correct Master Configuration ID that the central electronic module (CEM) transmits. This is normally due to an open-circuit on the CAN cables or some other interference in communication.

The diagnostic trouble code (DTC) is intended to detect whether the central electronic module (CEM) has defective software, but is more common when there are faults in the CAN network or faults in the power supply to the control modules. A combination of E003- codes makes it easier to localize the fault, see the section on "Multiple diagnostic trouble codes (DTCs) and extended diagnostics". On the other hand, the diagnostic trouble code (DTC) is not stored at the same time in all control modules. This depends on the power supply to the control modules (e. g. X / 15 / 15I / 30).

The diagnostic trouble code (DTC) can be stored if incorrect software is downloaded into a control module or if a control module is moved from one car to another. This is why moving control modules between cars is not permitted. If several or all control modules have stored diagnostic trouble code (DTC) E003, this may be due to an incorrect signal configuration having been downloaded into the central electronic module (CEM). This is not particularly likely in practice, however, but is more often due to a physical fault in the CAN network.

X/ 15I / 15 supplied control modules can detect the fault five seconds after the control module has been powered up (ignition on). The control module compares its own CAN configuration ID (SW version) with the CAN configuration ID that is continuously transmitted by the central electronic module (CEM). Diagnostic trouble code (DTC) E003 is stored by the control module if the central electronic module (CEM) ID is absent or is different from the anticipated value five seconds after the control module has been powered up. An incorrect CAN configuration ID may be the result of a control module having been taken from one car and installed in another, although the diagnostic trouble code (DTC) is usually stored due to the signal being completely absent. A control module that is supplied directly from the battery (30) does not follow the same start up procedure as other control modules, but receives information about the position of the ignition key via the CAN network. This means that a 30-supplied control module will not store diagnostic trouble code (DTC) E003 5 seconds after the ignition is switched on if there is a permanent fault. The control modules will store the diagnostic trouble code (DTC) after a time-out lasting approximately ten minutes instead.

NOTE: This means that for a 30-supplied control module, the diagnostic trouble code (DTC) will be stored or not depending on when then fault occurred.

A typical reason for E003 being stored is an open-circuit in the CAN cables. In this case, the diagnostic trouble code (DTC) is often stored together the codes CEM-1A51 to CEM-1A66.

Diagnostic trouble codes (DTCs) E000 and E001 in a control module (E000=HS-CAN, E001=LS-CAN)

Diagnostic trouble code (DTC) E001 indicates a fault in the data communication on the CAN network. This can be due to interference of various types or if a control module is sending incorrect messages. Monitoring for this type of fault takes place continuously. The diagnostic trouble codes (DTCs) are originally intended to indicate contact bounces of if incorrect messages are sent over the network, but can also be stored in the event of a short-circuit between the two CAN cables or if communication only functions on one of the two cables. It takes a couple of seconds from the fault occurring to its detection.

Another important cause of these codes is if a control module has been disconnected from the network without the battery cable having been disconnected from the negative terminal (in such cases removing the ignition key does not help) or if the signal on the CAN cables is "weak" or disrupted. This can occur if communication is only working on one of the CAN cables or if one of the network resistors in the network is not working. The network resistors on the low speed network are located in the upper electronic module (UEM) and the rear electronic module (REM). On the high speed network, the resistors are located in the anti-lock brake system module (ABS)/brake control module (BCM) and in the electronic throttle module (ETM), except for Bosch EMS MY02 and later where the resistors are located in the brake control module (BCM) and the engine control module (ECM).

In certain cases, the diagnostic trouble code (DTC) may be stored if a control module sends data at the wrong transfer speed or if the crystal in a control module is defective.

Diagnostic trouble codes (DTCs) in the event of lost signal, rapid indication of faults on the CAN network

Some control modules, such as the engine control module (ECM), the electronic throttle module (ETM), the anti-lock brake system module (ABS) and the transmission control module (TCM) continually check the existence of each other and store diagnostic trouble codes (DTCs) in the event of missing signals. These diagnostic trouble codes (DTCs) are often due to different driving conditions and combinations of diagnostic trouble codes (DTCs) are often stored which can make fault-tracing more difficult. When attempting to recreate the fault, there is no guarantee that the same combination of diagnostic trouble codes (DTCs) will be stored. The detection of these diagnostic trouble codes (DTCs) is often more sensitive and they are usually stored more easily than CEM-1A51 to CEM-1A66 or CEM-DF03 to CEM-DF16. This can therefore be an indication of a short-term intermittent fault having occurred on the CAN network.

Below is a selection of diagnostic trouble codes (DTCs) that may or may not be stored in the event of an intermittent fault on the CAN network:

- ECM-928C (Bosch), ECM-922A (Denso), only when the engine is running. These diagnostic trouble codes (DTCs) indicate that the control signal for the cruise control is missing or could not be received by the engine control module (ECM)
- ECM-901A, ECM-901E, ECM-902A, ECM-911A, ECM-912A and ECM-913A for Bosch and ECM-901A, ECM-902A, ECM-911A, ECM-912A for Denso
- SRS-00D6, time-out for the seat belt buckle. This diagnostic trouble code (DTC) indicates that the supplemental restraints system module (SRS) has not received the status of the seat belt buckles from the central electronic module (CEM). The sensor for the seat belt buckles is directly linked to the central electronic module (CEM)
- SRS-00D5, status of the SRS indicator lamp in the driver information module (DIM)
- Discrepancies in the signal from the pedal position sensor between the directly connected signal and the signal over the CAN network. See the table below.

Engine control module (ECM) Bosch		
	ECM-959F	Fault when comparing the signals AP12T APU (Analog Pedal Unit) Analog and PWM (from the electronic throttle module (ETM))
Engine control module (ECM) Denso		
	ECM-9520	ETS, APM, PWM, electrical fault, signal too low
Monitoring the engine control module (ECM)		
Bosch		
	ECM-510F	No speed signal
Denso	ECM-510D	No speed signal
	ECM-A02B	No signal from the anti-lock brake system module (ABS)/brake control module (BCM)
	ECM-902A	Communication fault with the electronic throttle module (ETM)

Multiple diagnostic trouble codes (DTCs) and extended diagnostics (counters and freeze frames)

The detection time for faults in the CAN network varies depending on the diagnostic trouble code (DTC). This means that for different fault occurrences, different diagnostic trouble codes (DTCs) can be stored in different control modules. Several diagnostic trouble codes (DTCs) in different control modules can be confusing and must be investigated at the start of fault-tracing to check for any link between the various codes.

It is now possible to read off extended diagnostic trouble code (DTC) information, normally counters and frozen values. This can also help with fault-tracing on the CAN network as it can provide information about diagnostic trouble codes (DTCs) that are stored simultaneously. Remember that the function using counters can be implemented differently in different control modules, which can make it difficult to compare cycles between different control modules.

When performing fault-tracing on a car with many intermittent E003 and CEM-1A51 to CEM-1A66 diagnostic trouble codes (DTCs), this can be made easier by checking the affected control modules. Copy the diagram in the service manual, Data communication for the relevant car model, and write down all diagnostic trouble codes (DTCs) and counters at the relevant control modules. Check any conclusions can be drawn from where the diagnostic trouble codes (DTCs) are stored. If the diagnostic trouble codes (DTCs) are in control modules at one end of the CAN network, this can give an indication of where the fault may be located.

Limp-home modes and characteristics of control modules in the event of faults in the CAN network

When a control module cannot receive messages from the central electronic module (CEM) it will go into Limp-home mode. In such cases, the control module can retain part of its functionality. The remaining

functionality varies in different control modules. If a fault occurs after a control module has been started up, it will normally retain the most recent values as the Limp-home values. There are exceptions, such as the fuel gauge in the driver information module (DIM).

Some clear examples for the low speed side network:

- Driver information module (DIM):

  As the driver information module (DIM) only displays signals received from the CAN network, it will soon be evident if signals are lost. The display of various signals will disappear at slightly different times due to some filtering of the signals in the driver information module (DIM). The values on the gauges are normally frozen for around ten seconds before dropping to zero and the driver information module (DIM) shuts down. If only one control module has disappeared from the network, the driver information module (DIM) can display the first indication of this. An example of this is where the rear electronic module (REM) stops communicating, which is indicated by the fuel gauge dropping to zero

- Climate control module (CCM):

  This control module must retain some of its functionality even if the CAN communication is lost. It is also a very good indication of whether the CAN communication has been lost, as the LEDs will light up exactly ten seconds after the ignition key has been turned to positions one or two. Other symptoms: if the AC compressor is not working, apart from the first second when the function is checked by the engine control module (ECM), this can indicate a fault in the climate control module (CCM)>central electronic module (CEM)>engine control module (ECM) chain. Another very obvious symptom is that the blower fan continues to operate for up to ten minutes after the key is removed from the ignition switch. This is because the climate control module (CCM) is powered via Extended-X from the central electronic module (CEM). The climate control module (CCM) normally switches off the blower fan and other functions when it does not receive a signal over the CAN network after the ignition key has been removed. If there is no CAN communication, the climate control module (CCM) will continue to operate until the central electronic module (CEM) switches off the power supply

- Driver door module (DDM)/Passenger door module (PDM):

  The module will be set to a resting mode and no functions will be performed, such as setting the mirror or operating the power windows

- Power seat module (PSM):

  The memory function in the seat will not work. Stored positions for seats and mirrors will not work when the car is unlocked with a remote control

- Upper electronic module (UEM):

  The seat belt reminder will be lit, even though the belt is secured in the seat belt buckle. It will not be possible to lock or unlock the car using the remote control

- Audio module (AUM):

The radio retains most of its functionality. However, the buttons on the steering wheel will not work

- Rear electronic module (REM):

  The fuel gauge is not working and it will not be possible to lock/unlock the rear doors using the central locking switch. The heating loops in the rear windshield and the rear folding head restraints will not work

- Steering wheel angle sensor module (SAS):

  The anti-skid system will not work

- Steering wheel module (SWM):

  Buttons on the steering wheel and the turn signal lamp stalk will not work. However the horn will still work because it is connected directly to the central electronic module (CEM).

Some clear examples for the high speed network:

- Engines:

  Cannot be started as a result of no communication between the central electronic module (CEM) and transmission control module (TCM) + engine control module (ECM)

  - Level 1: No cruise control function
  - Level 2: Accelerator pedal "heavy". Poor response
  - Level 3: Present Limp-home mode. The engine speed (RPM) is controlled via the injectors.
- Electronic throttle module (ETM):

  The node has three Limp-home levels:

  - Level 1: No cruise control function
  - Level 2: Accelerator pedal "heavy". Poor response
  - Level 3: Present Limp-home mode. The engine speed (RPM) is controlled via the injectors.
- Transmission control module (TCM):

  It is not possible to use all the gears.

  NOTE: If the control module has gone into Limp-home due to an open-circuit in the CAN communication, the functionality will not return during the cycle, even in the event of the fault disappearing.

- Anti-lock brake system module(ABS)/Brake control module (BCM):

  The remaining functionality depends on what fault has occurred. In the event of a fault in the AYC sensor, the indicator lamp lights and DSTC stops working. Faults in the wheel sensors cause the indicator

lamp to light and the ABS function to disappear, although there is still braking assistance. The unit can lose certain diagnostics in Limp-home mode

- Central electronic module (CEM):

  Extremely large loss of function. It is worth noting that the control module has separate circuits for the high speed and low speed networks. This means that it is possible to communicate with the control module via the high speed network even when the low speed network has a fault.

Fault-tracing tips

If the central electronic module (CEM) has stored diagnostic trouble code (DTC) CEM-DF14 CAN low short-circuit to ground, this does **not** mean that the central electronic module (CEM) is necessarily the control module which short-circuits the cable. The short-circuit may be from any part of the cable to any ground terminal or ground lead. The fault may be in a cable harness, which is the most common situation, or in a control module. Note that the diagnostic trouble code (DTC) can be stored in some control modules but not in others, and that the short-circuit in this case can be far from the control module that stores the diagnostic trouble code (DTC).

Statistically there is a high likelihood of the fault being in the cable harness (check behind the audio module (AUM), at the supplemental restraint system module (SRS), the terminals for the CAN cables in the connectors on the transmission control module (TCM) and the engine control module (ECM). Note that terminal pins (P/N 9441394) can be used to check the mating surface in the female connectors for the CAN cables. If the mating surface is defective or the terminal pins detach too easily, the female connector socket must be replaced (P/N 9442486).

If diagnostic trouble code (DTC) E001 is stored continually and the cable harness is free of faults, all control modules containing diagnostic trouble code (DTC) E001, apart from the central electronic module (CEM), must be disconnected from the CAN network. Delete the diagnostic trouble codes (DTCs) in the remaining control modules and read off diagnostic trouble codes (DTCs) again to, see if the fault disappears. Then connect the control modules again, one by one, until the diagnostic trouble code (DTC) recurs. If VIDA (Volvo scan tool) can communicate with the car when the ignition key is in position 0 and 1 but not in position 2, the fault is probably in a 15-supplied control module.

The above method can also be used in other scenarios. On rare occasions, control modules can begin sending irrelevant messages on the CAN network. This can prevent the correct messages from getting through. The result can be one or more E003 or CEM-1A51 to 1A66 diagnostic trouble codes (DTCs). It may be difficult to determine which control module is causing the interference. In this case, the above method may be the only way of finding the fault source.

If none of the control modules on the LS-CAN respond but a response is received from the control modules on HS-CAN

The central electronic module (CEM) protects the CAN network from short-circuits caused by the data connection device. This is achieved with the aid of four internal relays, one for each CAN cable. The relays are closed when the central electronic module (CEM) receives a signal from VIDA (Volvo scan tool) on the communication cable.

If the above problem occurs, check the following:

1. The scan tool cable. This cable has given problems before. Try with a different cable and a different VCT2000 (or appropriate scan tool).
2. Continuity and signal level on the communication cable
3. Continuity and signal level in the CAN cables between the connector and the central electrical module (CEM).

If points one to three do not produce a result, the fault is probably a permanent cable fault in the CAN network or in a control module. Continue fault-tracing according to "CAN network hardware and measurement methods" below.

CAN network hardware and measurement methods

The CAN network is connected using resistors (120 ohms each) between the two CAN cables (green (GN) for CAN-L, white (W) for CAN-H) in some control modules. The two control modules in the low speed network (in principle the passenger compartment) that have resistors are the rear electronic module (REM) and the upper electronic module (UEM). In the high speed network (in principle the engine compartment), the position of resistors depends on the engine type and model year. For model years 99-01, the resistors are positioned in the anti-lock brake system module/brake control module (ABS/BCM) and the electronic throttle module (ETM). In cars from model year 02 with Bosch EMS, the electronic throttle module (ETM) is no longer part of the CAN network. The resistor in this case is located in the engine control module (ECM).

Measurement method

To localize a permanent fault in the CAN network, the resistance can be measured in the network. When taking resistance readings, the battery negative terminal must be disconnected and the resistance must be close to 60 ohms. An open-circuit in one or both CAN cables will produce a resistance of 120 ohms. The recommended approach is to measure the resistance using a breakout box connected to the central electronic module (CEM). This has the following advantages:

1. The reading is taken with the central electronic module (CEM) connected. Note that open-circuits in the anti-lock brake system module/brake control module (ABS/BCM), steering wheel angle sensor module (SAS), power seat module (PSM), passenger door module (PDM), driver's door module (DDM) audio module (AUM) will not affect the reading as these control modules are not connected in series. The reading only checks the "main artery in the CAN network". However, a short-circuit between the two cables will be detected
2. There is easy access to the low speed network, the high speed network and the cables between the central electronic module (CEM) and the connector
3. If a multimeter is connected, this can be positioned in front of the driver's seat and the cable harness/connectors can be twisted above the central electronic module (CEM). It is then easy to, see any changes in resistance
4. As in point 3, twist and turn the cables/junction behind the radio where the cables lie against the rear wall of the engine compartment
5. As in point 3, move the cables/junction connected to the cable harness in the headlining by the A-post
6. As in point 3, ask someone to twist and turn the cables under the cooling box for the central electronic module (CEM) and the transmission control module (TCM).

If for some reason it is not possible to use the breakout box for the central electronic module (CEM), the low speed network can be measured using the breakout box for the power seat module (PSM) or in its connector when the power seat module (PSM) is disconnected.

These measurements are particularly effective when diagnostic trouble codes (DTCs) CEM-1A51 to 1A66 and E003 or E001 are stored without diagnostic trouble codes (DTCs) CEM-DF03 to DF16 being stored. When taking resistance readings, also check that none of the cables are short-circuited to ground or voltage, which ought to have stored CEM-DF03 to DF16. The resistance should be several kohms.

For intermittent faults, the oscilloscope is very useful. The reading should be taken with all control modules connected and powered up using the breakout box. Check that the voltage on CAN-H never exceeds 4.5 V and that CAN-L is never below than 0.5 V. Note that the oscilloscope in VIDA (Volvo scan tool) is not sufficiently accurate (measurement speed too low) for detailed measurement of the traffic on the CAN network, but can give an indication of the voltage levels that exist and whether communication exists or not.

NOTE: **Never take readings directly in the connector using the test probes of the multimeter. This can result in damage to the connector and entail insufficient contact when the connector is reassembled. Use a terminal pin instead.**

FAULT TRACING

FAULT TRACING

COUNTERS, DESCRIPTION

Counter

A useful fault-tracing tool is the Diagnostic Trouble Code (DTC) counter. The control module stores 6 different counters for each Diagnostic Trouble Code (DTC), which describes the occurrence. The counters can be used to determine when and how often a fault has been detected. Using the counters for the Diagnostic Trouble Code (DTC) it is possible to, see if the fault has only been registered during the current operating cycle or whether it has been detected previously.
If a fault is intermittent it is possible to determine how intermittent the fault is by studying the values of the different counters.
Example:

- Counter 1 = 15 Counts the number of operating cycles since the fault was last validated.
- Counter 3 = 69 Counts the number of operating cycles since the fault was first validated.
- Counter 4 = 1 Counts how many times the fault has occurred since the first time the fault was first validated.
- Counter 5 = 91764 The counter adds the time in seconds for which the control module has been operating since the fault was first validated and the diagnostic trouble code (DTC) was stored.
- Counter 6 = 0 The counter adds the time in seconds for which the test, the diagnostic, has run since the fault was first validated and the diagnostic trouble code (DTC) was stored.
- Counter 7 = 0 The counter adds the time in seconds for which the fault has been validated since the fault was first validated and the diagnostic trouble code (DTC) was stored.

In the examples given above, counter 1 gives the number of operating cycles where the diagnostic was run without a fault being detected. Counting takes place from when the fault was last detected. Counter 3 is the total number of operating cycles regardless of whether the diagnostic was run or not. Counter 4 shows the number of operating cycles where the diagnostic detected a fault. Counters 3 and 4 start to count from the first operating cycle after the operating cycle when the fault was first detected.
In the example, counter 4 = 1, which means that the fault was detected twice. One can, see that no fault was detected during the relevant operating cycle. Depending on the number of operating cycles and the customer's driving pattern, it can assist in ruling out this control module from the customer's current problems. The counters can help us understand how intermittent the fault can be. If the counters 1 = 0, 3 = 0 and 4 = 0 it indicates that there have not been any operating cycles since the fault was detected and that the fault was probably generated in the workshop.
For an operating cycle to be recognized certain requirements may be necessary, for example, increasing the engine coolant temperature. In certain cases ignition on, ignition off and ignition on again are counted as an operating cycle.
Counter 5 can be useful if the fault was detected in this operating cycle. The time can be used to determine more exactly when the fault occurred.

NOTE:
Not all counters need be implemented in a control module, this varies from system to system. The possible counters are described below.

Counter	Function
A (see the graph in, see **Fig. 1**) Counter 1	The graph in, see **Fig. 1** illustrates the time at which a fault occurs. In the illustration the control module has detected a fault in the second cycle. This fault has then occurred a total of 5 times. The counter can be read off for each diagnostic trouble code (DTC) in the control module in which this is implemented. Operating cycles are marked with vertical lines. An operating cycle usually begins at ignition on and finishes when the ignition is switched off.
C#1 (see the graph in, see **Fig. 1**) Counter 2	Counts the number of operating cycles since the fault was *last* validated. This information can be used to determine whether the fault is active during the current operating cycle or not. The fault is present now if the value is zero. This counter is also used for most systems to give "Permanent fault" and " Intermittent fault" text messages in VIDA when reading off a diagnostic trouble code (DTC).
C#3 (see the graph in, see **Fig. 1**) Counter 3	Counts the number of operating cycles since the fault was *first* validated. When a fault has been validated, the counter will count up by 1 for each subsequent operating cycle. The same as counter C#1 but monitors the number of cycles since the first fault occurred.
C#4 (see the graph in, see **Fig. 1**) Counter 4	Counts the number of operating cycles in which the fault was validated since it was first validated. Counts the number of times the fault has occurred since the first time.
C#5 Counter 5	The counter assesses the number of seconds the control module has been operating since the fault was first validated and the diagnostic trouble code (DTC) was stored. The time the control module has been operating is only counted when it is active, not in "sleep mode".
C#6 Counter 6	The counter assesses the number of seconds the test (the diagnosis) has been operating since the fault was first validated and the diagnostic trouble code (DTC) was stored.
C#7 Counter 7	The counter assesses the number of seconds the fault has been valid since it was first validated and the diagnostic trouble code (DTC) was stored.

DESCRIPTION OF COUNTER

Counter
There are eight different counters that are stored individually for each diagnostic trouble code (DTC). For an intermittent malfunction, the values of the different counters can be studied to determine how intermittent the malfunction is. All counters do not need to be implemented in one control module, this varies from system to system. The possible counters are described below.

Counter	**Function**
C#1	Counts the number of operating cycles since the malfunction was *last* validated. This information can be used to determine whether the malfunction is active during the current operating cycle or not. The malfunction is present now if the value is zero.
C#2	Counts the number of operating cycles since the malfunction was *last* validated, where test for the diagnostic trouble code was performed without the malfunction being detected and validated. When a test is performed, no malfunction is detected, the counter will count up by 1 for each operating cycle.
C#3	Counts the number of operating cycles since the malfunction was validated *the*

	first time . For each completed operating cycle the counter will count up by 1.
C#4	Counts the number of operating cycles in which the malfunction was validated since it was first validated. Counts the number of times the malfunction has occurred since the first time.
C#5	Counts the number of warm-up cycles since the MIL-light has gone off.
C#6	The counter counts the number of internal detections of the malfunction that have been performed for the diagnostic trouble code. When this counter reaches + 127, the control module considers that the malfunction is active right now. When counter is at value -127 the malfunction is not active. The value is reset to zero at each new operating cycle. If the value increases toward +127 the control module has detected a malfunction and, for each internal test, the value counts up. When the malfunction is not active, the control module counts down to minimum -127. Value can only be changed when the control module has started the test for the diagnostic trouble code. The increments with which the control module counts up or down the value may vary between control modules.
C#7	Shows maximum value for current operating cycle.
C#8	Shows maximum value for current and/or earlier operating cycle.

DESCRIPTION OF STATUS IDENTIFIER

Status identifier
There are different status identifiers that can be read out for each diagnostic trouble code (DTC). The control module tests each connection more or less continuously. By reading out the diagnostic trouble code (DTC) and the associated status identifier (which detects the malfunction and stores the DTC), information about the test is obtained. Not all status identifiers need to be implemented in one control module, this varies from system to system. All status identifiers are reset and start counting again each time the control module is powered up and when erasing diagnostic trouble codes (DTCs). The possible status identifiers are described below.

Status identifier	**Explanation**
SI#01	The malfunction is validated now. Shows if the control module detects the malfunction right now. It is only when the test is in progress that the control module can detect malfunction and generate diagnostic trouble code.
SI#02	The malfunction is validated in the current operating cycle. Shows if the control module has detected the malfunction any time during this operating cycle.
SI#03	Intermittent not yet confirmed diagnostic trouble code.
SI#04	Confirmed diagnostic trouble code.
SI#05	Test status in current and/or earlier operating cycle. Shows if control module has performed test for this diagnostic trouble code in current and/or earlier operating cycle.
SI#06	The malfunction is validated in an earlier operating cycle. Shows if the control module has detected the malfunction any time during an earlier operating cycle.
SI#07	Test status in current operating cycle. Shows if control module has performed test for this diagnostic trouble code in current operating cycle.
SI#08	Request activate warning light/text message. Information about the diagnostic trouble code activates a warning light or text message.

ENGINE COOLANT

WATER QUALITY

The water that may be used in Volvo engine cooling systems together with Volvo original coolant must meet certain requirements. Tap water, for example, contains too much chlorine, minerals and salts. Water that does not meet the requirements according to the specification can cause corrosion and deposits in the cooling system even if the water is mixed with coolant. See specification. See **WATER QUALITY**

If in doubt about whether the water meets the requirements according to the specification, Volvo original coolant must be mixed 50/50 with distilled water (battery water) or ready mixed Volvo original coolant must be used.

When changing coolant or components in the cooling system, the system must be flushed clean with water that meets the specification or with distilled water. Alternatively the cooling system can be flushed with ready mixed Volvo original coolant.

ENGINE

Engine - Cleaning, Inspection and Adjustment

CYLINDER LEAKAGE TEST

CYLINDER LEAKAGE TEST

GENERAL METHOD DESCRIPTION

THE CYLINDERS CAN BE CHECKED FOR LEAKAGE AS AN ALTERNATIVE TO A COMPRESSION TEST

Fig. 1: Compression Gauge In Cylinder
Courtesy of VOLVO CARS CORPORATION

Using this method, the amount of leakage at the engine cylinders is measured and it is possible to locate the

source of any leaks.

A similar check can be performed using a compression gauge by injecting oil in the cylinder. However, this can cause a build-up of coke.

The result will not always be decisive or precise.

In addition, the VIDA station or the Volvo System Tester (VST) must always be connected afterwards to erase any diagnostic trouble codes (DTCs).

HOW IS THE CYLINDER CHECKED FOR LEAKAGE?

- The engine should be run to operating temperature so that the thermostat is open
- The piston in the cylinder that is being checked must be set to Top Dead Center (TDC) at the compression phase
- A metered air pressure is connected to the relevant cylinder via an adapter that is secured in the spark plug / glow plug well
- A gauge is used to measure the size of the leakage from the cylinder.

  This is a pressure sensor with a regulator and displays the size of the leak expressed as a percentage.

  This allows the extent of any problem to be determined.

FAULT-TRACING

The source of a leak can be located by analyzing sound at the following points.

Exhaust pipe	Faulty exhaust valve
Intake manifold / throttle body (TB)	Faulty intake valve
Dip stick hole / Crankcase ventilation	Faulty piston / piston ring
Adjacent cylinder	Faulty cylinder head gasket
Radiator	Faulty cylinder head gasket / cracked cylinder wall. Also check for bubbles in the expansion tank.

A mechanic's stethoscope or a rubber hose can be used as a listening device.

NOTE: There is leakage at the piston rings even on a perfect engine.

This is the only place where a small leak is permissible.

CHECK

If a leak is detected that is assumed to come from the valve system, first check that the piston in the relevant cylinder is at top dead Centre (TDC).

Then try to set the piston just prior to top dead Centre (TDC) and redo the test.

When repeating the leak test on the same engine, there are usually variations in the results of the measurements.

This is due to changes in the engine coolant temperature (ECT) and the piston not reaching the same position as in the previous test, and is affected by the amount of oil on the piston rings at the time.

MEASURING VALVE CLEARANCE

Fig. 77: View of Measuring Valve Clearance
Courtesy of VOLVO CARS CORPORATION

NOTE: Measurements should only be taken on a cold engine. A suitable temperature is approximately 20°C (68°F).

The camshaft cams on the cylinder whose valves are to be measured should point straight up in the direction of the valves.

Tighten the screws of the press tools. M7. See **TIGHTENING TORQUE**

see **9995752**

Press with your finger so that the feeler gauge lies parallel with the top of the lifter (see figure). In order to obtain as correct a reading as possible, move the feeler gauge laterally when measuring clearance.

Valve clearance measured on a cold engine (approx. 20°C/68°F) should be: Exhaust valve: 0.45 ± 0.05 mm.

Differences in valve clearance for different engines / ambient temperatures:	
- 0.01 mm	15°C
+ 0.01 mm	25°C
+ 0.02 mm	30°C
+ 0.03 mm	35°C
+ 0.04 mm	45°C

Fig. 78: Rotating Cam to Repeat Measurement
Courtesy of VOLVO CARS CORPORATION

see **9997261**

Repeat the work by loosening the screws of the press tools and rotating the camshaft until the next cam pair is correctly positioned. Tighten and continue measuring until all exhaust valves have been measured.

Note the results carefully.

CORRECTING MEASURED CLEARANCE

Remove the press tools. Lift off the camshaft. Adjust clearance by replacing the lifter. Alternative lifters are available as a spare part/spare part kit. Reinstall the camshaft and press tool. Tighten to 17 Nm. Check valve clearance again on the adjusted valves.

WHEN CORRECT VALVE CLEARANCE HAS BEEN MEASURED

Remove the press tools.

A CPS solenoid does not have a built in spring. It is therefore necessary to press the valve in slightly during fault-tracing to get the solenoid to work satisfactorily during the test. Use a short M8 screw or similar.

The lack of spring also means that it may sound as if something is loose inside the solenoid if it is shaken. This is completely normal.

CAULKING (B5254T2; 2003-2007)

CAULKING

Fig. 92: Bearing Housing, Cylinder Block And Intermediate Section
Courtesy of VOLVO CARS CORPORATION

On engines manufactured of aluminum the camshaft bearing housing (1) cylinder block (2) and the intermediate section (3) may be caulked.

NOTE: The cylinder heads that are chill-cast may not be caulked.

Each individual case is assessed as to whether caulking can be carried out or not depending on the location of the oil leakage.

Fig. 93: Identifying Center Punch And Rounded Tips
Courtesy of VOLVO CARS CORPORATION

Caulking involves in the event of leakage knocking the material together using a special caulking tool.

Two caulking tools are required. Use center punches (1). Grind down the tips so they become round. One is to be ground so the rounded tip (A) is 2 mm. The other is ground so the rounded tip (B) is 4 mm.

NOTE: Use the protective goggles supplied with the leak tracing kit.

Use: Isopropanol, 1161721

Use an UV light to localize the pore. Carefully wash round the pore with Isopropanol. Check with a UV light that all the oil has been removed.

Fig. 94: Identifying Tool Angle And Pores

Courtesy of VOLVO CARS CORPORATION

WARNING: Use protective goggles.

If the pore is small, it is sufficient to place the tool (2 mm) directly on the pore and hit it with a copper or plastic hammer. If the pore is larger, angle the tool (2 mm) and drive the material in a circle toward the pore (2). If there is a lip around the pore, caulking (tool 4 mm) should be carried out in a spiral form toward the pore (3).

Fig. 95: Driving Material Toward Pore Using 2 mm Tool
Courtesy of VOLVO CARS CORPORATION

Drive the material toward the pore (1) using the 2 mm tool. Seal using the 4 mm tool (2).

Use: Isopropanol, 1161721

Wash with Isopropanol. Check with a UV lamp that there is no oil around the leakage point.

Test drive for 45 minutes as set out below to reach an oil temperature of about 80°C.

1. Allow the engine to idle for 20 minutes.
2. Test drive the car for 15 minutes.
3. Allow the engine to idle for a further 10 minutes.

Check using a UV light that the sealed area no long leaks. If leakage remains, repeat the caulking.

REMOVAL

BLOCKING THE FLYWHEEL

Fig. 415: Blocking The Flywheel Using Gear Sector 999 5112
Courtesy of VOLVO CARS CORPORATION

Use gear sector see **9995112** .

Applies only to certain engine versions with self adjusting clutches:

Secure the clutch automatic adjustment.

Use counterhold see **9995677** . Locate the counterhold, see below.

ALIGNING THE COUNTERHOLD FOR AUTOMATIC CLUTCH ADJUSTMENT

Fig. 416: Aligning Counterhold For Automatic Clutch Adjustment
Courtesy of VOLVO CARS CORPORATION

Applies only to certain engine versions with self adjusting clutches:

The three pins on the counterhold lock the automatic adjustment.

Position the tool as illustrated.

Ensure that all the three pins (see the illustration) go into the groove in front of the tensioner springs for the automatic adjuster.

Press the ring against the pressure plate. Pull out the counterhold springs. Secure the three hooks in the center holes of the outer edge.

INSTALLING THE COMPRESSION TOOL

Fig. 417: Compression Tool 999 5662 Installed
Courtesy of VOLVO CARS CORPORATION

Install compression tool see **9995662** , together with the conversion kit on the clutch. The tool is modified as described in the tool bulletin.

Ensure that the hooks grip correctly, although without clamping the adjuster springs.

Centre the compression tool and tighten the screw to light contact against the diaphragm spring. At the same time, check that the hooks on the tool are in position.

Applies only to clutches without self adjustment:

Note the position of the handle with slots. Then screw in by **not more than two turns** .

Remove the clutch and clutch driven plate

Applies only to certain engine versions with self adjusting clutches:

Compress the clutch so that the automatic adjuster is not under load.

If the clutch is worn, the counterhold turns the automatic adjustment to the original position marking.

The marking consists of two stamped arrows.

Then continue to screw in the compression tool until the diaphragm spring has pressed the pressure plate to a free position.

A click can be heard when the clutch pressure plate snaps out.

Remove the clutch and the clutch driven plate .

RELIEVING THE LOAD FROM THE CLUTCH DIAPHRAGM SPRING

Fig. 418: Identifying Clutch Diaphragm Spring
Courtesy of VOLVO CARS CORPORATION

SAFETY INFORMATION, GASOLINE

WARNING: Risk of explosion and fire.

Make sure there are no open flames or sparks in the vicinity of fuel

system components. It is possible that there is no obvious warning in the form of odor or irritation before a poisonous or hazardous situation arises. This could be immediate or delayed.

WARNING: Gasoline for engine operation can contain considerable amounts of benzene, which is toxic if inhaled. The concentration of gasoline fumes must be kept very low. Make sure there is suitable ventilation when handling and using gasoline.

The greatest of care must be taken to avoid the serious consequences of inhaling if there is fume build-up from spills in enclosed spaces.

High concentrations cause eye/nose/throat irritation, nausea, headaches, depression and signs of insobriety. Very high concentrations result in quick loss of consciousness.

Special methods are to be applied to clean and maintain gasoline storage tanks. Gasoline must not be used as a cleaner. Gasoline must not be taken into the mouth.

• In the event of skin contact: Take extreme care when handling hot fluids. Always wash spilled fluid off of exposed skin immediately.

• In the event of consumption: Consumption can result in mouth and skin irritation and absorption from the stomach can result in drowsiness and loss of consciousness. Small amounts could be fatal to children.

• In the event of inhalation: Inhaling fluid into the lungs, through vomiting, is extremely dangerous. Gasoline dries out the skin. Long-term or repeated exposure can cause irritation and skin inflammation.

• In the event of contact with the eyes: Fluid in the eyes causes severe pain.

CAUTION: Fuel injection equipment is manufactured with extremely tight tolerances and minimum clearance.

CAUTION: It is vital that the utmost cleanliness is upheld when working with these components. Make sure the area around the vehicle is as clean and free of dust as possible.

CHECK FOR AIR LEAKS IN THE INTAKE SYSTEM

PREPARATIONS

Check that all hoses are undamaged and are in place with their hose clips tightened.

CONNECTING

Remove fresh air hose from mass air flow (MAF) sensor.

Install tool see **9995545** with pressure regulator see **9995544** on fresh air hose and tighten hose clamp.

Use hose clip to seal crankcase ventilation hose.

Remove oil filler cap.

Remove the lower hose from the canister purge (CP) valve.

CHECK

Fig. 1: Gentle Hissing Sound Heard From Oil Filler Opening
Courtesy of VOLVO CARS CORPORATION

Connect the compressed air hose and adjust the regulator to obtain a pressure of **maximum 0.3 bar** .

A gentle hissing sound can be heard from the oil filler opening. This is due to the opening of an intake valve and the leakage of cylinder pressure past the piston rings.

If a leak is suspected spray a soap solution onto the area.

Small bubbles are permissible between throttle body (TB) and intake hose (if made of plastic). No bubbles are permissible with rubber hose.

Check for air leakage from canister purge (CP) valve. No leakage is permissible.

COMPRESSION TEST

Diagnostic trouble codes (DTCs) will be stored because the engine speed (RPM) sensor and (where applicable) the camshaft position (CMP) sensor have been disconnected.

Have an assistant hold the accelerator pedal (AP) depressed at wide open throttle (WOT) during the compression test.

The starter motor is activated with the ignition key.

The ignition must be switched off after each cylinder has been compression tested.

NOTE: **It will no longer be possible to control the throttle if the ignition is on for longer than 2 minutes.**

The throttle function is controlled by the control module.

Use compression meter see **9999689**

with extension sleeve see **1158540** .

CATALYTIC CONVERTER DIAGNOSTIC

CATALYTIC CONVERTER DIAGNOSTIC

The three-way catalytic converter (TWC) stores oxygen found in the exhaust gases and uses it to make toxic gases more environmentally friendly. The catalytic converter is a three-way catalytic converter (TWC) in which HC (hydrocarbons) and CO (carbon monoxide) are oxidized and NOx (nitrous oxide) is reduced. As the three-way catalytic converter (TWC) ages its ability to store oxygen drops. This reduces the conversion capacity of the three-way catalytic converter (TWC). To avoid dangerous emissions the engine control module (ECM) checks three-way catalytic converter (TWC) efficiency. In brief, this check is carried out as follows.

Two heated oxygen sensors (HO2S) are used to check the catalytic converter; one upstream and one downstream of the catalytic converter. The main function of the heated oxygen sensors (HO2S) is to measure the oxygen content in the exhaust gases so that the engine control module (ECM) can maintain the engine fuel/air mixture at around lambda=1.

The catalytic converter diagnostic consists of two checks. The first checks how quickly the three-way catalytic converter (TWC) begins to operate, and the second is a response time check. When starting cold the control module checks how quickly the three-way catalytic converter (TWC) begins to operate. If the target lambda is already varying during this check, the following check is not carried out.

When the engine is at operating temperature, lambda variations are created (Dither function) by the diagnostic, adding a deviation to the target lambda signal which the fuel control system regulates towards. The deviation changes between positive and negative values so that the fuel/air mixture changes between rich and lean. The discharge through the three-way catalytic converter (TWC) is determined by studying the variation of lambda and the response from the rear probe.

On a poorly performing three-way catalytic converter (TWC), the deviation changes can easily be calculated by the rear probe response time. On an efficient three-way catalytic converter (TWC) this is more difficult, because the variations take too long to go through.

NOTE: The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.

SMOKE MACHINE

The smoke machine generates smoke that is used to detect leaks in the EVAP- system. Follow the instructions that are supplied with the smoke machine to use it and to check for leaks.

Information

To be able to check for leaks in the whole EVAP-system, the connections must be disconnected and the smoke machine must be connected in such a way that the smoke is not stopped by non-return valves or by the EVAP-pump being closed. Two persons should help each other when checking for leaks. One that operates the smoke machine and one that visually checks for leaks.

HINT: To, see the smoke easier, use a powerful light with flood lights.

The smoke contains a colouring agent that leaves invisible marks in case of leaks. These marks are seen as small green spots when they are illuminated with UV-light and yellow screened glasses are used for viewing.

CONNECTING SMOKE MACHINE

Fig. 10: EVAP-Pump And Outlet Hose
Courtesy of VOLVO CARS CORPORATION

This shows the procedure for a 5-cylinder turbo engine.

Other engine alternatives have similar EVAP-systems.

Disconnect the EVAP-pump, located under the inlet manifold in front of the engine in rubber mounting. Press together the lock on the outlet hose (1) and pull it loose. Press aside the lock on the connector (2) and disconnect it.

Fig. 11: Clamping Shut Hose Closest To Connection To Inlet Manifold With Locking Pliers

Clamp shut the hose closest to the connection to inlet manifold with locking pliers.

Fig. 12: EVAP-Pump With Quick-Coupling
Courtesy of VOLVO CARS CORPORATION

The EVAP-pump sucks in hydrocarbons through the line mounted with quick-coupling (1). The hose (2) receives vacuum since it is connected to the inlet manifold.

The non-return valve results in gas only being able to flow in to the inlet. The other hose (3) leads in to the connection before the turbo.

Disconnect the hose (4) at the EVAP-pump. Connect the smoke machine to the hose that you just disconnected. Fill the hoses with smoke and check that the hoses and non-return valves are intact.

CHECK FOR LEAKS IN PLASTIC HOSE TO CARBON CANISTER

Insert the smoke machine's tapered nozzle in the line that was installed with quick-coupling in the EVAP-pump (1). Lift up the vehicle. See: **JACKING POINTS, BODY** .

Fill the system with smoke. Check that there are no leaks in the hose to the carbon canister.

NOTE: It is natural that smoke seeps out at the tank pipe.

- the hose with quick-coupling
- the connector
- the EVAP-pump with its rubber mount.

NOTE: Make sure that the locks on the quick-coupling and connector are locked securely.

Check the fuel pressure

Absolute pressure: Fuel pressure in fuel system + air pressure.

Relative pressure: Fuel pressure in fuel system.

The air pressure is approx. 100 kPa at sea level. VIDA measures the fuel pressure in absolute pressure. External pressure gauge (pressure gauge) measures the fuel pressure in relative pressure.

Fuel line pressure. See **SPECIFICATIONS**

The following method must be used when reading the fuel line pressure on the fuel rail:

CAUTION: Remove the oil filler cap.

CHECKING THE AIR LEAKAGE

Connect the compressed air hose and adjust the regulator so that a max. pressure of 0.2 bar is obtained.

A weak hissing sound can be heard through the oil filler, this is due to an intake valve being open and the pressure in a cylinder leaking past the piston rings.

Spray soap and water solution if uncertain if leaks exist

Small bubbles are permitted between the throttle body (TB) and the inlet hose if it is plastic. If the inlet hose is rubber then no bubbles are permitted.

Rectify any leakage.

CHECK

Adjust the regulator to obtain a maximum pressure of **0.3 bar** (0.15 psi). There may be a gentle hissing sound from the oil filler opening. This is due to the opening of an intake valve and the leakage of cylinder pressure past the piston rings.

Check components and connections. See: **CHECKING COMPONENTS**.

If a leak is suspected, spray a soap solution onto the area. Check for air leakage from the canister purge (CP) valve. No leakage is permissible.

QUICK CHECK, TURBOCHARGER (TC)

STOP ENGINE AND LISTEN TO TURBOCHARGER (TC) AT THE MOMENT OF STOPPING

Fig. 16: Listening To Turbocharger At Moment Of Stopping
Courtesy of VOLVO CARS CORPORATION

Normally the rotating turbocharger (TC) components stop moving after the engine.

If this is not the case:

Remove the inlet hose from the compressor housing.

Check afterwards that:

- the compressor wheel spins easily when rotated.
- axial- and radial play feels normal.
- the compressor wheel does not rub in the compressor housing.

REPLACING TURBOCHARGER (TC)

In a number of cases the turbocharger (TC) has been changed unnecessarily. This happened because some play has been felt when checking (the shaft floats on an oil film).

Play should always be checked before replacing, to determine if the bearings are worn.

The turbocharger (TC) should always be replaced complete:

- plug all terminals on the old turbocharger before it is sent away.

ENGINE

Lubricating And Oil System - Cleaning, Inspection and Adjustment

OIL CONSUMPTION TEST (2003-2012)

GENERAL INFORMATION

Some oil consumption is normal when an engine is running. The oil consumption varies depending on different factors:

- The condition of the engine (how well the engine is maintained)
- Blocked or damaged air filter
- Driving conditions - large loads, or excessive idling
- Oil grade and viscosity
- Cylinder capacity - in general a larger motor consumes a greater amount of oil than a smaller engine
- Engine power - a stronger engine consumes more oil than a smaller powered engine
- Oil level - too high a level (above the maximum mark on the dip stick) results in increased oil consumption.

Normal oil consumption

Running-in period

The oil consumption can be as much as 1 liter per 1, 000 km during a running-in period of approx. 5, 000 km if the engine is new or replaced (replacement of piston ring).

Driving between 5, 000 and 150, 000 km

Normal driving: up to 0.25 liters per 1, 000 km is considered normal oil consumption.

Driving at high speed/with heavy trailer: up to 0.40 liters per 1, 000 km is considered normal oil consumption.

Mountain/alpine driving: up to 0.50 liters per 1, 000 km is considered normal oil consumption.

The above stated values for oil consumption can be used as guidelines if there is a suspicion that oil consumption is unusually/abnormally high.

NOTE: The oil consumption can be as much as the following at 150, 000 km. The oil consumption can be approx. 0.35 - 0.55 liters per 1, 000 km under all conditions.

To determine the exact oil consumption a test drive of at least 1, 000 km must be performed under controlled conditions. The oil must be weighed before and after the test drive. This way the exact oil consumption can be calculated.

Abnormally high oil consumption

If the customer points out that the car consumes an abnormal amount of oil, the checks below must be carried out before carrying out corrective action.

- Ask the customer what their driving conditions are. See **GENERAL CAUSES OF HIGH OIL CONSUMPTION**)
- Check for oil leaks
- Check that the crankcase ventilation is not blocked
- Check that the correct dip stick is in the engine. Check that the dip stick is pushed down as far as possible
- The car must be parked on level ground when measuring the oil. The engine should be driven at normal operating temperature on the road (not idling) for 30 minutes. The engine must then be left for 15 minutes before noting the oil level.

GENERAL CAUSES OF HIGH OIL CONSUMPTION

Overfilling

If the oil has been filled above the recommended maximum level, oil is forced up against the cylinder walls and is ejected through the crankcase ventilation. The oil level must not be filled above the maximum mark on the dip stick.

Oil grade

Using a non Volvo recommended oil grade can cause increased oil consumption. The oil contains a larger amount of volatile molecules if the oil is too thin. Thin oil has difficulty in maintaining a comprehensive oil film on the cylinder walls at higher temperatures. This results in increased engine wear and increased oil consumption

Hard driving

Long and continuous driving at high engine speed (RPM) causes high engine temperature. The oil thins and consumption increases. Hard cornering at high engine speed (RPM) causes the oil to be forced against the side of the cylinder block and against the cylinder walls, resulting in increased oil consumption.

Mountain driving

Numerous and long periods of regular engine braking also causes high engine temperature. More oil is sucked into the cylinders due to an increased negative pressure in the intake pipe.

Idling

Driving the car in urban traffic conditions, where the engine may be running for long periods but only covering short distances, does not necessarily increase oil consumption but the ratio of oil consumption to distance travelled may be misleading.

Climate

In hot climates, the engine is required to work harder at a higher temperature. This increases oil consumption.

MECHANICAL CAUSES OF HIGH OIL CONSUMPTION

Leaks

Worn crankshaft and crankshaft seal, external leakage, for example leaking gaskets.

Crankcase ventilation

Overpressure in the crank case caused by blocked crankcase ventilation.

Pistons and piston rings

Worn piston ring groove. Worn, scratched, broken or damaged piston rings. Blocked scraper rings. Incorrectly installed piston rings.

Cylinder walls

Worn or scratched cylinder walls.

Valves

Worn valve guides or valve stem. Worn, damaged or missing valve stem seals.

Cylinder head

Internal leakage between the oil ducts and leakage to the combustion chamber.

MEASURING THE OIL CONSUMPTION

General

There are two methods of determining the oil consumption. The oil is measured using a dip stick in the first method, before and after driving a test distance of 2000 km. This gives a sufficient first indication of the oil consumption. The second method consists of weighing the oil in the sump after driving 1000 km.

To reach as a correct result as possible, with both methods, the car must be driven to normal operating temperature (not idling) for 30 minutes before noting the oil level or draining the oil. Change the oil and replace the oil filter to ensure that a Volvo approved oil is used in the engine during the test period. Also replace the air cleaner (ACL) before measuring. The car must be standing on a flat surface and in the same position when measuring or weighing before and after the driven test distance.

Measuring using the dip stick

Replace the oil, oil filter and air cleaner. The oil must be Volvo approved.

Drive the car to operating temperature for 20-30 minutes (not idling). This is so that the oil reaches normal operating temperature.

Switch off the engine. Leave the engine switched off for 15 minutes.

Check the oil level. Top up with oil if necessary. Fill to the maximum mark on the dip stick.

Run the engine for 5 minutes so that the existing oil and the additional oil mix.

Switch off the engine for 15 minutes. Note the oil level on the dip stick. Note the odometer setting and vehicle data on the included form, see **FORM FOR MEASURING OIL CONSUMPTION**.

Drive the car 2000 km, or until the oil level has dropped to the minimum mark on the dip stick.

Drive the car to operating temperature for 20-30 minutes (not idling). This is so that the oil reaches normal operating temperature.

Switch off the engine. Leave the engine switched off for 15 minutes.

Measure the oil level on the dip stick using a sliding gauge. Note the result.

Complete the information on the form.

Weighing

Drive the car to operating temperature for 20-30 minutes (not idling). This is so that the oil reaches operating temperature.

Drain the oil from the oil trough for 15 minutes. A large amount of oil is collected in the cylinder head when the car is running. This factor, together with the design of the splash guard in the oil pan, means that it takes a long time for the oil to drain out of the engine. The oil must **not** be reused.

WARNING: **Take care when draining the oil. Use protective goggles and protective gloves. Hot oil can cause personal injury**

Replace the oil filter and air cleaner.

Fill with the specified amount of Volvo approved engine oil.

Drive the car to operating temperature for 20-30 minutes (not idling). This is so that the oil reaches normal operating temperature and the oil filter fills.

Carefully weigh an empty clean container (± 1 gram).

Drain the oil from the oil trough into the container for 15 minutes.

WARNING: Take care when draining the oil. Use protective goggles and protective gloves. Hot oil can cause personal injury

Carefully weigh the container + oil.

Fill the engine with the weighed oil. Ensure that as much oil as possible leaves the container.

Weigh the empty container. The container may weigh more than it did the first time due to the remaining oil film. The difference in weight is taken from the weighed oil weight.

Note the oil weight odometer setting and vehicle data on the included form, see **FORM FOR MEASURING OIL CONSUMPTION**.

Drive the car 1000 km, or until the oil level has dropped to the minimum mark on the dip stick.

Ensure that the engine is at normal operating temperature. Drive to normal operating temperature if necessary for 20-30 minutes (not idling).

Carefully weigh an empty clean container (± 1 gram).

Drain the oil from the oil trough into the container for 15 minutes.

WARNING: Take care when draining the oil. Use protective goggles and protective gloves. Hot oil can cause personal injury

Carefully weigh the oil + container. Deduct the weight of the container.

Complete the information on the form

If abnormal oil consumption is discovered when measuring, the engine needs to be remedied as follows.

CORRECTIVE ACTION FOR HIGH OIL CONSUMPTION

Conditions

A new and improved type of piston ring was introduced for naturally aspirated engines from model year 1999 inclusive and for turbocharged engines from model year 2000 inclusive. From model year 2000 inclusive the same piston rings are used on both naturally aspirated engines and turbocharged engines.

A car with an engine with the new piston rings can be expected to use 0.05-0.15 litres of oil every 1000 km.

A car with an engine with the earlier piston rings can be expected to use 0.10-0.20 litres of oil every 1000 km.

If the engine consumes more than 0.4 litres of oil every 1000 km, the following checks must be carried out to

check whether the oil consumption problem is in the cylinder head, crankcase ventilation or piston ring and sleeve surface.

Check

Remove the intake manifold.

Inspect to, see if there is an oil film or drops of oil in the cylinder head intake passage and/or oil on the valve stem and top of the valve crown.

Conclusions

If there is not an abnormally large amount of oil in the intake passage and valves and the oil consumption gradually, from being acceptable, begins to quickly increase, or consumption is between 0.30-0.80 litres per 1000 km, the problem is in the piston, piston ring or cylinder sleeve surface.

Faults in valve stem seals for example, or internal leakage in the cylinder head cannot be completely ruled out.

If the oil consumption has always been high, or there are traces of oil in the intake passage and valves, or the oil consumption is above 0.80 litres every 1000 km, the problem is probably in the cylinder head.

The cause could be leaking valve stem seals, internal leakage in the cylinder head or a fault in the crankcase ventilation (other than a blockage).

Corrective actions

If the problem seems to be in the crankcase ventilation, this must be thoroughly checked and remedied if necessary, before reconditioning or replacing the cylinder head.

If the problem seems to be with the piston, piston ring or cylinder sleeve surface, the engine should be reconditioned or if necessary, replaced.

RECONDITIONING

Replacing piston rings

A corrective action is to replace the two lower piston rings (scraper ring and oil ring).

If the upper piston ring (compression ring) is undamaged it must not be replaced. Increased oil consumption may result if the compression ring is replaced.

CAUTION: Check that the upper piston ring (compression ring) faces the right way (see below)

It is important that the uppermost and centre rings are installed the correct way up.

The lower ring can be installed any way up.

Distribute the piston ring openings as follows.

Early version

Fig. 1: Compression Rings
Courtesy of VOLVO CARS CORPORATION

A. Compression ring

This is marked with text or with a circle. The marking must be facing upwards. It may be difficult to read the text, a magnifying glass may be required.

B. Scraper ring

The cut out must be turned downwards. The text must be on the top of the ring.

C. Oil ring

Earlier versions of the oil ring are not marked and can be installed any side up.

Later versions of the oil ring are divided into 3 sections. These slotted rings can be installed with either side facing up.

CAUTION: New versions of the piston ring assembly cannot be combined with earlier versions of the piston

Late version

CONCLUSIONS FOR CORRECTIVE ACTION

Replacing piston rings

As a first corrective action the piston rings should be replaced. Normally only the scraper ring and the oil ring must be replaced. The compression ring should only be replaced if absolutely necessary.

Replacing valve stem seals

If traces of oil are found on the valve crowns, in the ducts or on the valve stems, the valve stem seals should be replaced.

Thoroughly check the cylinder head. Check for internal leakage.

Replacing the cylinder head

If traces of oil (described above) are found and faults are found on the cylinder head, internal leakage for example, the cylinder head must be replaced.

Replacing the cylinder block and pistons

If damage is found in the cylinder block (worn cylinder bore, deep scratches etc.) the cylinder block, pistons and piston rings must be replaced.

Replacing the engine

The engine must be replaced if the problem cannot be remedied using the above corrective actions.

B5244S6, news

Fig. 2: Identifying B5244S6 Engine Components

Cylinder head

Cylinder head with CVVT (Continuous Variable Valve Timing) for both the intake and exhaust camshafts.

Change over angle CVVT:

- intake = 60 crankshaft degrees
- exhaust = 30 crankshaft degrees.

Wide Range. When cold starting in positions P, N (automatic transmissions) or neutral (manual transmissions), the engine speed may initially reach approx.2000 rpm before dropping immediately to approx.1650 rpm for 15 - 20 seconds. The engine then runs at a low ignition setting and lean lambda. The engine speed (RPM) then drops

to idle speed approx.750 rpm. This is to reduce the emissions during the warm-up phase.

The camshaft toothed belt is reinforced to increase service life. The belt tensioner has a new gasket to ensure an optimal seal.

Pistons

Graphite coated pistons.

The pistons have a two piece oil control ring. The design of a stainless steel ring with nitrated steel spring ensures good service life. The thickness of the oil control ring is 2 mm.

Evaporative emission canister (EVAP canister) in the air cleaner (ACL) housing

An EVAP canister is integrated in the air cleaner (ACL) housing.

There is no service interval for the EVAP canister. If the canister is damaged and needs to be replaced, the entire cover must be replaced.

The canister absorbs the hydro-carbons which return through the air cleaner when the engine is switched off. When the engine is started, the absorbed hydro-carbons enter into the air flow and are combusted.

Crankcase ventilation

The connection nipple for the crankcase ventilation at the intake manifold has been modified to provide more even distribution of the crankcase vapors between the cylinders. A positive temperature coefficient (PTC) element prevents freezing.

The flame trap has a labyrinth which efficiently separates oil from the crankcase vapors before they are returned to the intake manifold.

Resonator

There is a resonator on the hose between the mass air flow (MAF) sensor and the ETA (Electronic Throttle Actuator). This is to satisfy European legal requirements for vehicle sound levels. By modifying the unfavorable frequencies which occur at high engine speeds, the sound levels of the intake and exhaust systems are reduced.

When the pulses affect the measurement function of the mass air flow (MAF) sensor, software in the engine control module (ECM) compensates for this. Because the pulses have been reduced, the software has also been modified from previous engine control modules (ECM).

If the resonator is removed, the signals from the mass air flow (MAF) sensor will be incorrectly interpreted by the engine control module (ECM).

Electrical cooling fan for the control module box

The fan starts when the temperature in the control module box reaches approx. +70 °C and stops at approx. +65 °C. The temperature sensor in the engine control module (ECM) is used as a reference.

Three-way catalytic converter (TWC)

The manifold with the catalytic converter, CCC (Closed Coupled Catalyst), has double ceramic monoliths.

The Under Floor Catalyst (UCF) has a ceramic monolith.

B5244S, ULEV (Ultra Low Emission Vehicle)

Differences from B5244S6:

- CVVT (Continuous Variable Valve Timing) only for the intake camshaft. Change over angle CVVT intake = 60 crankshaft degrees
- Emissions regulations apply for 100 000 miles/10 years
- The pistons have three piece oil control rings, 2.5 mm thick
- A new manifold gives improved torque at low engine speeds
- No EVAP canister in the air cleaner (ACL) housing
- Only an under floor catalyst with two ceramic monoliths and integrated muffler.

B5244S6, fuel injection system

Fig. 3: Identifying B5244S6 Fuel Injection System

Combined fuel pressure / fuel temperature sensor

Fuel temperature sensor

A negative temperature coefficient (NTC) sensors transmits a voltage signal (corresponding to a certain temperature) to the engine control module (ECM). The signal is used to compensate for changes in fuel temperature. The injection period is regulated to provide compensation.

Example: If the engine is restarted after a short stop, the temperature of the fuel in the fuel rail will have increased. The engine control module (ECM) uses the signal from the sensor to compensate for the increased temperature by extending the injection period. (The volumetric energy content of hot fuel is lower than cold fuel).

Fuel pressure sensor

For information about this function, see "Control of the fuel pump".

Fuel injection system miscellaneous

- Fuel tank constructed from stainless steel
- Fuel pump (FP) which is activated as required
- Leak diagnostic based on the overpressure principle
- DENSO fuel control system
- New DENSO ETA (Electronic Throttle Actuator).

5. Roll over valves
6. Control module for the fuel pump (FP) (Pump Electronic Module)
7. Wiring
8. Fuel pump
9. Service hatch
10. Water separator, LSD (Liquid Separation Device).

- In order to satisfy statutory requirements in California, the fuel tank is made of stainless steel. The release of hydro-carbons is reduced because steel is less permeable than plastic
- Volume 70 liters
- The fuel filler pipe, which is manufactured from stainless steel, is welded to the fuel tank. The small diameter of the pipe limits the flow of air into the fuel tank when refueling. The air supply effects the degree to which the canisters full up and therefore emissions
- Fuel tank filler cap with more efficient valves

- The geometric shape of the fuel tank enables three roll-over valves to be used
- The service hatch is made of plastic. The hatch is secured using a stainless steel nut
- The B5244S6 engine has an evaporative emission (EVAP) system with two canisters. There is a water separator upstream of the canisters. The EVAP canister closest to the fuel tank has three chambers filled with active carbon. There is another canister, HCS (Hydro Carbon Scrubber), connected in series. Based on a honeycomb coated with active carbon
- B5244S has only one canister (does not have HCS).

Fuel pump

1. Pump with an integrated PRV safety valve (Pressure Relief Valve)
2. PVV (Pressure Ventilation Valve)
3. Fuel level sensor
4. Fuel filter
5. Non-return valve
6. Ejector pump.

A fuel pump (FP) with a flow which is adjusted to suit the requirements. By controlling the power consumption

of the pump based on the fuel requirement of the engine, the following is achieved:

- long service life (all components in the system must last 150 000 miles/15 years)
- tailored power consumption.

A DC motor drives a pump which works on the turbine principle.

Pump flow is as follows at:

- full load approx. 90 liters per hour at 400 kPa (corresponding to 380 kPa at the fuel rail)
- idle speed approx. 1.2 to 2.0 liters per hour.

The power consumption varies from approx. 8 A at full capacity to approx. 2 A at idle speed.

Valves

PVV (Pressure Ventilation Valve)

The valve compensates for surges in pressure that occur when, for example, fuel injection ceases during engine braking. Allowing fuel to continually pass through the valve ensures rapid pressure compensation. Any excess fuel flows into the pump housing.

The pressure is limited to 400 kPa (corresponds to 380 kPa at the fuel rail).

When the engine is switched off, the valve maintains a residual pressure in the fuel injection system to prevent condensation.

Non-return valve

Releases fuel into the pump housing when the fuel tank is refilled having been almost empty. The valve is closed if the car tilts so that fuel remains in the pump housing.

PRV (Pressure Relief Valve)

Safety valve integrated in the fuel pump (FP). The valve opens between 550 kPa - 850 kPa.

Ejector

Continuously fills the pump housing with fuel. approx. 10-15 liters per hour always flows from the fuel pump (FP) through the ejector and back to the pump housing.

Fuel filter

The fuel filter is in the pump housing. Cannot be replaced.

Fuel pump control

Fig. 6: Identifying Fuel Pressure Regulation
Courtesy of VOLVO CARS CORPORATION

The following components are included in the system which controls the fuel pump:

- Engine control module (ECM) with built-in atmospheric pressure sensor
- Fuel pressure sensor
- Control module for the fuel pump (FP) (Pump Electronic Module).

Function

A piezo-electric fuel pressure sensor transmits a voltage signal to the engine control module (ECM) about the actual pressure in the fuel rail.

The engine control module (ECM) compares the signal with the signal from the atmospheric pressure sensor in the engine control module (ECM). The fuel pressure is regulated so that the pressure in the fuel rail is always 380 kPa above the atmospheric pressure (i. e. the difference in pressure is 380 kPa).

Depending on factors such as engine speed and load, the engine control module (ECM) transmits a calculated pulse width modulated (PWM) signal to the control module for the fuel pump (FP). The control module for the fuel pump sends the signal on to the fuel pump at a higher frequency.

The PWM signal corresponds to a certain feed voltage to the pump. This in turn corresponds to a certain pump

flow rate. By adapting the supply voltage, the load of the pump matches the fuel requirement.

If the engine is running at higher engine speeds (RPM) and under high load, the speed of the pump is higher (greater flow) than at small loads and low engine speed (RPM).

If the pressure briefly rises to 400 kPa, during acceleration for example, the fuel flow is compensated by reducing the injection period. For longer periods of time, such as a couple of seconds, the fuel pressure is lowered via the fuel pump to compensate.

A diagnostic trouble code (DTC) is stored If the pressure sensor detects that the pressure remains at the same value for a long time. The emissions warning lamp lights if the same fault persists or returns.

A diagnostic trouble code (DTC) is stored in the fuel pressure system if there is no signal from the pressure sensor or if it is implausible. The fuel pump (FP) is controlled using a PWM signal. The signal is calculated from the fuel flow - based on the injection periods and the desired pressure.

ENGINES, GENERAL MODIFICATIONS

5 and 6 cylinder diesel and gasoline engines

Generator

The first ramp up of the charge current (after start) is always completed, irrespective of the engine speed (rpm). This increases the engine load successively, preventing sudden loads. Otherwise the ramp up characteristic of the charge current is maintained.

Previously the ramp up was interrupted and full charge current was permitted when the generator speed exceeded approx. 3400 rpm, even during the first ramp up.

Function:

- The charge current is 0 A until the generator speed has reached approx. 1450 rpm. The charge regulator continues to maintain the charge current at 0 A for a few further seconds
- Ramp up then begins. For a number of seconds the charge current increases linearly from 0 % to 100 % of the maximum power handling capacity. If the requirement is less than the power handling capacity, it takes less than 6 seconnds to reach the controlled condition.

General:

- All 5 cylinder engines have generators with freewheels
- 6 cylinder engines have fixed pulleys
- All 5 and 6 cylinder engines have 140 A generators.

Unique to the XC90:

- The 5 cylinder engines (diesel and gasoline) with rear air conditioning have 160 A generators
- The 6 cylinder engines have 160 A generators.

5 and 6 cylinder gasoline engines

Pistons

All engines (except B5204TX, B5234TX and B5244TX) have pistons with the mantles coated with graphite. This reduces noise and lowers the friction between the piston and the cylinder, particularly when cold starting and under large loads at low engine speeds. Also improves resistance to scoring.

Pulsation damper fuel rail

The engines have a pulsation damper, ATD (Air Tube Damper), in the fuel rail. The pulsation damper is filled with air and helium. Helium is used during manufacture to check for leaks.

Combined temperature/pressure sensor for intake air (turbocharged engines only)

The temperature/pressure sensor, T-MAP (Temperature/Manifold Absolute Pressure), is on the outlet side of the charge air cooler (CAC).

The sensors work according to the previous principles.

There are new resistance values for the temperature sensor.

5 cylinder naturally aspirated and turbocharged engines

The flame trap has a labyrinth which efficiently separates oil from the crankcase vapors before they are returned to the intake manifold. Does not apply to Bi-Fuel cars.

The camshaft toothed belt is reinforced to increase service life. The belt tensioner has a new gasket to ensure an optimal seal.

B6294T and B6294S2

The diameter of the gear drive on the coolant pump has been reduced. The number of teeth has been reduced from 21 to 17. The pump operates at a higher speed, improving the flow and therefore engine cooling.

New tension pulley for the camshaft. The increased diameter compensates for the smaller gear drive for the coolant pump. The timing belt is unchanged.

B5244S/S2

- CVVT (Continuous Variable Valve Timing) only for the intake camshaft. Change over angle CVVT intake = 60 crankshaft degrees
- A new manifold gives improved torque at low engine speeds

- Start is based on the Wide Range concept
- Electrical cooling fan for the control module box. The fan starts when the temperature reaches approx. +70 °C and stops at approx. +65 °C. The temperature sensor in the engine control module (ECM) is used as a reference
- The connection nipple for the crankcase ventilation at the intake manifold has been modified to provide more even distribution of the crankcase vapors between the cylinders. A positive temperature coefficient (PTC) element prevents freezing.

Resonator

There is a resonator on the hose between the mass air flow (MAF) sensor and the ETA (Electronic Throttle Actuator). This is to satisfy European legal requirements for vehicle sound levels. By modifying the unfavorable frequencies which occur at high engine speeds, the sound levels of the intake and exhaust systems are reduced.

When the pulses affect the measurement function of the mass air flow (MAF) sensor, software in the engine control module (ECM) compensates for this. Because the pulses have been reduced, the software has also been modified from previous engine control modules (ECM).

If the resonator is removed, the signals from the mass air flow (MAF) sensor will be incorrectly interpreted by the engine control module (ECM).

ETA (ELECTRONIC THROTTLE ACTUATOR), DENSO

Fig. 12: Identifying Electronic Throttle Actuator Components

1. Hall sensor
2. Spring
3. Spring
4. Throttle
5. DC motor
6. Terminal pins
7. Gear wheel
8. Gear sector
9. Permanent magnets.

Function

The engine control module (ECM) uses a PWM signal to control the position of the DC motor and with it the position of the throttle.

By changing the polarity of the power supply, the DC motor can be run in both directions.

Two permanent magnets in the gear sector on the throttle spindle are used to check the position of the throttle.

- The permanent magnets affect the two Hall sensors in the cover
- When the throttle spindle is turned, the position and strength of the magnetic field changes, which affects the Hall sensors
- Internal circuits convert the hall signals to two voltage signals which are transmitted to the engine control module (ECM).

The two signals are offset internally.

- The voltage of the main signal is 0.6 V when the throttle is shut. The voltage increases by 40 mV per degree that the throttle is opened. The voltage is approx. 4 V at wide open throttle (WOT)
- The voltage of the redundant signal is 1.48 V when the throttle is shut. The voltage increases by 32 mV per degree that the throttle is opened. The voltage is approx. 4.2 V at wide open throttle (WOT).

In order for the engine control module (ECM) to determine whether the voltage signals are plausible, the actual values are compared with stored desired values. A diagnostic trouble code (DTC) is stored if the values are outside certain tolerances. In certain situations, depending on the nature of the fault, this may mean that the power supply to the DC motor is broken. If this happens, the throttle, through the use of springs, is moved to a position which makes the car drivable (with limited driveability).

Function, continued

- The conditions for running the adaptation are that the ignition key is turned from position I to position II and when the engine is turned off. The adaptation is stopped when the car is cranked (i. e. the ignition key is turned to position III)
- During adaptation, the throttle switches from the Limp Home mode to the mechanically closed position. The engine control module (ECM) updates the values if these deviate from the stored values
- The ETA (Electronic Throttle Actuator) has a return spring and a Limp Home spring. The springs are always checked after the engine is switched off
- The DC motor first closes the throttle. The Limp Home spring then resets the throttle to the Limp Home position. The throttle is then opened a few degrees, whereupon the return spring closes the throttle to the Limp Home position. A diagnostic trouble code (DTC) is stored if the throttle does not reach the Limp Home position within a certain time
- Diagnostic trouble codes (DTCs) related to the ETA (Electronic Throttle Actuator) are stored in the engine control module (ECM)
- During adaptation and spring control there is noise as the throttle moves to different positions
- The connector terminal pins are gold plated. A damaged terminal pin surface can interfere with the function
- The terminating resistor for the CAN network has been moved to the engine control module (ECM).

Diagnostics

- The diagnostics for the ETA (Electronic Throttle Actuator) have changed in comparison with the previous ETM (Electronic Throttle Module), Magneti-Marelli. The engine control module (ECM) continuously

reads off the engine torque. If the torque exceeds the expected value, for example if the throttle opening angle is too great, an error flag is stored and the system is reconfigured. This means that the torque is limited using other control mechanisms than the normal, for example fuel shut-off. The cruise control will be disengaged if it is in use

- The following happens, depending on the character of the fault. If the fault persists for a longer period a diagnostic trouble code (DTC) is stored. If the function returns to normal, the error flag goes out and the reconfiguration stops. No diagnostic trouble code (DTC) is stored if the error flag has only been stored for a short time
- In comparison to previous diagnostics, the tolerances before the diagnostic trouble code (DTC) is stored have increased, while the tolerance for the error flag have been reduced. The actual diagnostic trouble code (DTC) is first stored after the error flag has been in the fault area for a certain amount of time
- A new function has been introduced in VIDA for fault-tracing
- The new fault-tracing functions are based on there being a tool which reads out ranking values for relevant diagnostic trouble codes (DTCs)
- A ranking code for a diagnostic trouble code (DTC) indicates how closes the system is to storing a diagnostic trouble code (DTC)
- A high ranking value can result in reconfiguration, even though no diagnostic trouble code (DTC) is stored. The customer may have noticed a specific abnormality without a diagnostic trouble code (DTC) being stored. The cause of this can be identified by reading off the ranking values
- The tool can be used to read off two ranking value positions: "worst" and "latest". "worst" is the highest ranking value since the diagnostic trouble code (DTC) was erased. "latest" is the ranking value of the diagnostic trouble code (DTC) at the time it is read.

2. Turbocharger (TC) intake, connection
3. Connection, coolant pump intake pipe
4. Coolant outlet from the cylinder head
5. Coolant return
6. Crankcase gases to the intake for the turbocharger (TC)
7. Coolant from the cylinder head.

Evacuation

The evacuation system for the crankcase ventilation has been modified to ensure stable pressure in the crankcase. The crankcase gases are routed from the flame trap to, depending on the pressure conditions, the intake manifold (1) or the intake for the turbocharger (TC) (2).

When the pressure at the intake manifold is lower than at the intake for the turbocharger (TC), the gases flow to the intake manifold. When the pressure at the intake for the turbocharger (TC) is lower than in the intake manifold, the gases flow to the intake for the turbocharger (TC).

A non-return valve in the banjo screw for the crankcase ventilation connection (1) prevents the crankcase gases

from returning to the intake for the turbocharger (TC) when the pressure is high. This ensures that the gases are correctly evacuated and that the pressure in the crankcase is stable.

Heating

Coolant is used to heat the crankcase gases to prevent freezing.

The coolant flows from a duct in the cylinder head (4) to a common pipe which fills with coolant (7). The coolant then flows to the crankcase ventilation connection to the intake manifold (1). The coolant returns through a separate pipe (5) to the inlet (3) for the coolant pump.

The crankcase gases which flow to the turbocharger (TC), are warmed in a separate pipe (6) in the common pipe (7).

The location of the components and connections corresponds to the system required for diagnostics and service by authorities such as CARB (California Air Resources Board).

The flame trap is insulated using PUR foam. The flame trap has a labyrinth which efficiently separates oil from the crankcase vapors.

ECM-1000: CONTROL MODULE. SIGNAL TOO HIGH/SIGNAL TOO LOW. INTERMITTENT FAULT (B5254T2; B6294T; 2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION

Condition

Fig. 1: Engine Control Module
Courtesy of VOLVO CARS CORPORATION

If the control module registers that a signal from the internal atmospheric pressure sensor is faulty, the control module interprets this as a fault and ECM-1000 is stored after 20 seconds.

Substitute Value

The control module assumes 1013 hPa air pressure corresponding to sea level.

Possible Source

Signal too high:

- defective control module

Signal too low:

- defective control module

Fault symptom[s]

- Malfunction indicator lamp (MIL) lit.

ECM-1100: OUTSIDE TEMPERATURE SENSOR. FAULTY SIGNAL (B5254T2; B6294T; 2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION ECM-1100

Condition

Diagnostic trouble code (DTC) ECM-1100 (signal too high or too low) is stored if the signal from the outside

temperature sensor is outside of its normal range. The fault is diagnosed by the control module when the ignition is on or the engine is running.

Diagnostic trouble code (DTC) ECM-1100 (faulty signal) is stored if the signal from the outside temperature sensor is within its normal range but deviates from the calculated temperature. The fault is diagnosed by the control module when the engine is running, approximately 2 minutes after the engine is started.

Substitute Value

The values from the engine intake air temperature (IAT) sensor.

Possible Source

Signal too high:

- Short-circuit to ground in the signal cable
- Faulty outside temperature sensor.

Signal too low:

- Open-circuit in the signal cable
- Short-circuit to supply voltage in the signal cable
- Faulty outside temperature sensor
- Contact resistance in the terminals.

Faulty signal:

ECM-112C: ATMOSPHERIC PRESSURE SENSOR. SIGNAL TOO HIGH (B5254T2; 2005-2007)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION ECM-112C

Condition

Fig. 25: Engine Control Module
Courtesy of VOLVO CARS CORPORATION

The engine control module (ECM) checks the signal from the internal atmospheric pressure sensor.

The diagnostic trouble code (DTC) is stored if the signal from the internal atmospheric pressure sensor is higher than a certain value for a certain amount of time. The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute Value

- 1013 hPa (atmospheric pressure corresponding to sea level).

Possible Source

- Damaged engine control module (ECM).

Fault symptom[s]

- Malfunction indicator lamp (MIL) lit.

INTERNAL FAULT

REPLACING THE COMPONENT

The engine control module (ECM) has registered an internal fault.

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the engine control module (ECM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. Replace the engine control module (ECM) if the fault recurs.

Replace the engine control module (ECM) in the event of a permanent fault.

Check the ground lead between terminal #A58 (#A58) and mass air flow (MAF) sensor terminal #3. Check for an open-circuit.

With the ignition on and the mass air flow (MAF) sensor connector disconnected, the voltage at mass air flow (MAF) terminal #2 must be approximately U_{bat} , at mass air flow (MAF) terminal #3 it must be ground and at terminal #5 approximately 1 V.

The engine control module (ECM) calculates the expected mass air flow. The calculation is based on a number of different parameters. The calculated value for mass air flow is then compared with the measured value from the mass air flow (MAF) sensor.

The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the value for the measured air mass is lower than the calculated value for air mass.

The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute Value

Possible Source

- Air leakage in the intake system
- Contact resistance in the mass air flow (MAF) sensor connectors
- Short-circuit to ground in the signal cable
- Open-circuit in the signal cable
- Open-circuit in the power supply
- Damaged mass air flow (MAF) sensor.

ECM-130A: INTAKE AIR LEAKAGE. FAULTY SIGNAL (B5254T2; B6294T; 2003-2004)

DIAGNOSTIC TROUBLE CODE (DTC) INFORMATION ECM-130A

Condition

Fig. 145: Identifying Air Flow
Courtesy of VOLVO CARS CORPORATION

Engine control module (ECM) calculates the air mass in to the engine using, among other, information about the throttle position, engine RPM, EVAP-flow, air temperature, atmospheric pressure and pressure in the intake manifold. Then the calculated value is corrected so that it matches with the measured air mass from the mass air flow sensor. If Engine control module (ECM) registers that a too high correction of the calculated value is necessary, then diagnostic trouble code ECM-130A, Faulty flow, is stored.

For upgraded software, released during year 2006 or later, certain adjustments have been made. A greater correction of the calculated air mass will be allowed, which means that the system will be more tolerant to greater deviations in the air mass. Therefore this diagnostic trouble code is no longer necessary and has been removed.

DESIGN

IGNITION SWITCH

Fig. 146: Identifying Central Electronic Module (CEM) Connector Terminals
Courtesy of VOLVO CARS CORPORATION

The Engine Control Module (ECM) uses the signal from the ignition switch to detect when the ignition key has been turned to position II or III. When the key is in the ignition position (position II) or starting position (position III) a high signal (U_{bat}) is transmitted from the ignition switch to the engine control module (ECM).

The engine management system prepares for start-up (for example, temporarily activates the fuel pump (FP) relay). When the flywheel in the engine rotates, the engine speed (RPM) sensor signal is used to keep the fuel pump (FP) relay activated.

The fuse in the fusebox in the passenger compartment supplies current to the ignition switch.

The central electronic module (CEM) can diagnose the ignition switch.

BRAKE LAMP SWITCH

Fig. 147: Identifying Brake Lamp Switch
Courtesy of VOLVO CARS CORPORATION

The stop lamp switch is on the pedal box by the brake pedal. Its task is to supply the Engine control module (ECM) and Electronic throttle module (ETM) with information about the position of the brake pedal, if it is released or depressed.

One pin for the stop lamp switch is connected to battery voltage (terminal 30), the other pin is connected to the Engine control module (ECM) and the Electronic throttle module (ETM). When the brake pedal is in the released position, the stop lamp switch circuit is open, which means that 0 V is sent to the Engine control module (ECM) and the Electronic throttle module (ETM). If the brake pedal is depressed, the stop lamp switch circuit closes and battery voltage is sent instead.

The information from the stop lamp switch is used:

- together with information from the brake pedal position sensor to determine when it is permitted to use

cruise control or not
- to determine whether the information from the brake pedal position sensor is valid or not.
- when the CAN does not work, to be the only information to the Electronic throttle module (ETM) about the position of the brake pedal.

To determine whether the information from the stop lamp switch can be used or not, the Engine control module (ECM) and the Electronic throttle module (ETM) carry out plausibility checks.

For further information about which tests are carried out, see diagnostic trouble code (DTC) information for the relevant diagnostic trouble code (DTC).

BRAKE PEDAL POSITION SWITCH

Fig. 148: Identifying Brake Pedal Position Switch
Courtesy of VOLVO CARS CORPORATION

The brake pedal position sensor is mounted on the power brake booster in the engine compartment. Its task is to supply the Engine control module (ECM) with information about the position of the brake pedal.

The brake pedal position sensor is affected by the brake pedal push rod and is a sliding potentiometer. The sensor is supplied with 5 V from the engine control module (ECM) and the signal that varies depending on the position of the brake pedal is sent to the engine control module (ECM).

When the pedal is released the signal is 3 - 4.5 V, the precise value depends on the engine control system in the vehicle. The reason that the signal differs between different engine control systems, despite it being the same sensor, is that the control module's internal circuits differ, which affects the signal level from the sensor. When the pedal is depressed, the voltage from the sensor drops.

From model year 2002 the brake pedal position sensor is directly connected to the brake control module (BCM), information is sent over the CAN to the Engine control module (ECM).

The information from the brake pedal position sensor is used:

- together with information from the stop lamp switch to determine when it is permitted to use cruise control
- to determine whether the information from the stop lamp switch is valid or not.

To determine whether the information from the stop lamp switch can be used or not, the Engine control module (ECM) and the Electronic throttle module (ETM) carry out an electrical check of the circuits and plausibility checks.

For further information about which tests are carried out, see diagnostic trouble code (DTC) information for the relevant diagnostic trouble code (DTC).

ACCELERATOR PEDAL (AP) POSITION SENSOR

Fig. 149: Identifying Accelerator Pedal (AP) Position Sensor
Courtesy of VOLVO CARS CORPORATION

The accelerator position sensor is mounted by the pedal box in the passenger compartment and makes a mounting for accelerator pedal. Its main task is to supply the Engine control module (ECM) with information about the position of the accelerator pedal.

The accelerator pedal position sensor consists of two internal sensors, where one generates an analog signal and the other a pulse width modulated signal (PWM). The purpose of having two types of sensor is to eliminate the

probability of a fault from both signals from the sensors being incorrect, at the same time as them showing the same pedal position and the control module considers them correct.

The analog sensor supplies the Engine control module (ECM) with a signal that is approximately 0.5 V when the pedal is released and approximately 4.5 V when fully depressed. The sensor receives a voltage supply (5 V) and ground from the Engine control module (ECM).

The pulse width modulated (PWM) sensor supplies both the Engine control module (ECM) and Electronic throttle module (ETM) with a signal that has a fixed frequency of approximately 200 Hz where the pulse ratio varies between 8-88 %, depending on the position of the accelerator pedal.

The sensor receives voltage supply (12 V) via the main relay and is grounded via its own ground terminal. the signal to the Electronic throttle module (ETM) is electrically routed via the Engine control module (ECM), however, without affecting the signal at all.

Fig. 150: Identifying Communication Signals Between Accelerator Position Sensor, ECM & ETM

Courtesy of VOLVO CARS CORPORATION

The Engine control module (ECM) first uses the analog signal from the accelerator position sensor to calculate the desired throttle angle. The Engine control module (ECM) then transmits this request about the desired throttle angle via the CAN to the Electronic throttle module (ETM), which then fulfils the desired throttle angle and transmits back the information about the current throttle angle.

The pulse width modulated signal is used to monitor the analog signal. If there is a fault in the analog signal, the system uses the pulse width modulated (PWM) signal instead.

There are also situations when the PWM signal is used to control the throttle angle without a fault being detected on the analog signal. For example, when a fault has occurred in CAN communication between the Engine control module (ECM) and the Electronic throttle module (ETM), the throttle unit then does not receive any desired throttle angles from the Engine control module (ECM) but must then rely on the directly connected PWM signal to control the throttle.

On vehicles equipped with an automatic transmission, the sensor also contains a mechanical kick-down resistor that gives the driver a kick-down feeling when the pedal is depressed approximately 80 % of full pedal stroke. In this pedal position, the Transmission control module (TCM) permits kick-down to be activated. There is no separate switch in this sensor for kick-down.

To determine if the analog and the PWM signal are fault free, the Engine control module (ECM) and Electronic throttle module (ETM) carry out electrical checks and plausibility checks of the signals. If a fault is detected on any of the signals, the system uses the other signal.

For further information about which tests are carried out, see diagnostic trouble code (DTC) information for the relevant diagnostic trouble code (DTC).

CLUTCH PEDAL POSITION SENSOR (MANUAL TRANSMISSIONS ONLY)

Fig. 151: Identifying Clutch Pedal Position Sensor
Courtesy of VOLVO CARS CORPORATION

The clutch pedal position sensor is mounted between the clutch pedal and the pedal box. Its task is to supply the Engine control module (ECM) with information about the position of the clutch pedal.

The clutch pedal position sensor is a slide potentiometer and is supplied with 5 V from the Engine control module (ECM). The signal that varies depending on the position of the clutch pedal is sent to the Engine control module (ECM). When the pedal is released the signal is 3-4 V, the precise value depends on which engine control system the vehicle has. The reason that the signal differs between different engine control systems, despite it being the same sensor, is that the control module's internal circuits differ, which affects the signal level from the sensor. When the pedal is depressed, the voltage from the sensor drops.

The information from the clutch pedal position is used:

- to determine when it is permitted to use cruise control

- on certain markets to prevent the engine from being started if the pedal is released.

To determine if the information from the clutch pedal sensor can be used or not, the Engine control module (ECM) carries out an electrical check of the circuits and plausibility checks of the signal.

For further information about which tests are carried out, see diagnostic trouble code (DTC) information for the relevant diagnostic trouble code (DTC).

ELECTRONIC THROTTLE UNIT

Fig. 152: Identifying Electronic Throttle Unit
Courtesy of VOLVO CARS CORPORATION

The throttle unit is mounted on the engine intake manifold, the location can vary depending on engine type. 5 cylinder turbocharged engines and 6 cylinder engines have the throttle unit mounted under the intake manifold. Others have it mounted on the side of the intake manifold. The throttle unit's primary task is to control the amount of air to the engine from the request from the Engine control module (ECM).

The Electronic throttle module (ETM) is in the throttle unit, which means that it works as its own control module on the high speed side of the CAN.

The connection to the CAN takes up two of the six pins in the throttle unit's connector, the remaining four are taken up by:

- Voltage supply, 12 V via the engine control system's system relay.
- Ground terminals, separated from the engine control system's other ground terminals.
- Information about the brake pedal's position from the brake lamp switch.
- Information about the position of the accelerator pedal from the accelerator pedal unit's PWM sensor.

In order for the Electronic throttle module (ETM) to carry out the main task of controlling the air flow to the engine, the voltage supply, ground and contact with the CAN is sufficient. The other two signals about the position of the brake pedal and the accelerator pedal are used as a safety function in case a problem should occur with CAN communication. This makes it possible to continue driving, but with reduced driveability. The signals are used, among other things, to carry out a plausibility check of the desired throttle angle that comes from the Engine control module (ECM) via CAN.

In addition, the throttle unit consists of a further number of components such as throttle housing, throttle disc, throttle spindle, torque motor, throttle position sensor (potentiometers), spring unit etc.

In one end the throttle unit contains a stepless torque motor that is directly operated on the throttle spindle. The torque motor is supplied with 12 V and controlled by the Electronic throttle module (ETM). In the other end there is the throttle's spring unit and the mechanical stop for the smallest and largest throttle openings.

Fig. 153: Identifying Torque Motor & Spring Unit
Courtesy of VOLVO CARS CORPORATION

Outside the torque motor and the spring unit, out on the relevant end there is a throttle position sensor (potentiometer). The two position sensors are mechanically connected to each other via the throttle spindle.

1. Rotational hub with contacts.
2. Contacts, x 2
3. Contact track, 2 grooves.

For safety reasons, two position sensors send the same signal about the position of the throttle to the electronic throttle module (ETM).

If the signal from one of the position sensors is missing or faulty, the electronic throttle module (ETM) is still able to calculate the position of the throttle using the signal from the other position sensor. This maintains the driveability of the car.

Depending on the type of fault, the throttle system can reconfigure its own software (limp-home mode) and can

react in different ways.

The throttle is a so called "ball zone throttle" which means that the throttle housing's mating surfaces are "spherical" and provide a better solution per opening angle. This gives more accurate flow control from idling position up to approximately 20 % open throttle. The effect is a smoother start at throttle opening / acceleration.

A number of plausibility checks are carried out by the Engine control module (ECM) to determine whether the throttle unit and Electronic throttle module (ETM) works as intended or not.

For further information about which tests are carried out, see diagnostic trouble code (DTC) information for the relevant diagnostic trouble code (DTC).

ELECTRONICALLY CONTROLLED THROTTLE SYSTEM

Fig. 155: Electronically Controlled Throttle System Diagram
Courtesy of VOLVO CARS CORPORATION

There are a number of components that are important for the electronic throttle system to work, the most vital parts are the Engine control module (ECM), Electronic throttle module (ETM) and the accelerator pedal position sensor. The system does not have a mechanical link system or mechanical cable.

Fig. 156: Identifying Communication Signals Between Accelerator Position Sensor, ECM & ETM
Courtesy of VOLVO CARS CORPORATION

The main task of the throttle unit system is to regulate the amount of air to the engine from the driver's demands. The driver requests a certain toque from the engine by depressing the accelerator pedal. This information is received by the Engine control module (ECM) that, together with the torque request from other functions, calculates a desired throttle angle.

The torque request from other functions means that there are loads that the system compensates for without the driver knowing it, for example, when the AC compressor is to be switched on, the throttle needs to be opened to compensate for the extra load that is placed on the engine. If the system does not do this, the engine speed would drop and the torque out on the drive shaft would be reduced every time the AC compressor was switched on, and increase when switched off.

The Engine control module (ECM) sends the request about the desired throttle angle to the Electronic throttle module (ETM) via CAN. The Electronic throttle module (ETM) fulfils the desired throttle angle and sends the

information about the current throttle position back to the Engine control module (ECM) via CAN.

The Electronic throttle module (ETM), must not, under any circumstances, start to regulate the throttle position from its own request, but must always fulfill the desired throttle angle from the Engine control module (ECM). All signal transfers between the Engine control module (ECM) and Electronic throttle module (ETM) occur via CAN. If there is a problem with CAN communication, the information about the position of the accelerator pedal and the brake pedal is available via direct contact with the relevant sensor. This means that the vehicle can be driven, but with reduced driveability. In this position, the Electronic throttle module (ETM) only controls the throttle position after the accelerator pedal position, the throttle unit does not know whether the engine is running or not.

The Engine control module (ECM) and Electronic throttle module (ETM) carry out checks and plausibility checks continuously. If a fault is detected, the system carries out corrective actions, such as to activate a suitable reconfiguration and store diagnostic trouble codes (DTCs).

For further information about which tests are carried out, see diagnostic trouble code (DTC) information for the relevant diagnostic trouble code (DTC).

Below is general information about diagnostic trouble codes (DTCs) and a more detailed explanation regarding reconfigurations in the throttle system.

General information

When the Electronic throttle module (ETM) detects that the communication to the Engine control module (ECM) is interrupted in any way or broken, faults are stored in the Electronic throttle module (ETM). The information about these faults are sent to the Engine control module (ECM) as soon as communication is restored on the CAN. This means that the Engine control module (ECM) stores the diagnostic trouble codes (DTCs) for these faults as soon as the Electronic throttle module (ETM) delivers the faults. This, in turn, means that it is at this point that the frozen values for the diagnostic trouble codes (DTCs) are saved. For the Electronic throttle module (ETM) this means that the frozen values will be from a point in time after the diagnostic trouble code (DTC) first occurred.

For certain fault-tracing it is recommended that the ignition is switched off and switched on twice *before* erasing the diagnostic trouble codes (DTCs). This depends on the diagnostic trouble codes (DTCs) being generated according to the command from the Electronic throttle module (ETM), but as only the Engine control module (ECM) is erased, the Electronic throttle module (ETM) must be switched off completely (powerless) for its memory to be entirely erased. This must be carried out before the vehicle is test driven, otherwise the fault can be recreated in the Engine control module (ECM).

For the Engine control module (ECM) and Electronic throttle module (ETM) to be completely switched off the following must be carried out:

- Ignition off, then wait 3 minutes for the main relay/system relay to release the voltage supply to the Electronic throttle module (ETM) among other things.
- Then switch the ignition on and off again.
- Wait a further 3 minutes. If the engine cooling fan is running, wait a further 2 minutes after the engine cooling fan has stopped, to ensure that the Electronic throttle module (ETM) is switched off correctly.

Reconfigurations

A CAN or the throttle related fault can result in both the Engine control module (ECM) and the Electronic throttle module (ETM) switching to the reconfiguration mode (limp home). This mode is maintained for the rest of the operating cycle in which the fault occurred and in all following cycles where the fault is still present.

Depending on the detected type of fault, the control modules can assume different levels of reconfiguration. Reconfiguration covers everything from preventing cruise control being used due to a temporary break in communication with the cruise control switch, to the Electronic throttle module (ETM) using a fixed throttle angle and the Engine control module (ECM) controlling the engine speed with the ignition and fuel injection.

In the last named reconfiguration, the engine's idle speed may seem uneven because the Engine control module (ECM) for controlling the speed, closes the fuel supply to the cylinders individually. This reconfiguration (engine's behavior) must not be confused with an actual problem in driveability, which occurred before the reconfiguration.

For example, a short break in the voltage supply to the Electronic throttle module (ETM) means that the control module is reconfiguring itself. Be aware that the engine's behavior then depends on a fault being detected and that the fault is detected because of this behavior.

NOTE: **Upgraded software for the Engine control module (ECM) and Electronic throttle module (ETM) available during 2006 or later, has other conditions for determining when the reconfiguration must occur. The throttle system with this software is more tolerant of faults, which means that the reconfiguration in some cases occurs at other occasions.**

For information about how to identify the software in the control module, see: **IDENTIFYING UPGRADED SOFTWARE ECM/ETM**

The following reconfigurations (limp home) occur:

- **Fuel shut-off that follows the accelerator pedal position.** The engine's speed is controlled via fuel shut-off by the injector valves switching off one at a time. The engine's speed is determined by the position of the accelerator pedal sensor and the speed is maximized to approximately 5000 RPM. This reconfiguration can make engine idling seem to be uneven because the Engine control module (ECM) for controlling the engine's speed, closes the fuel supply to the cylinders individually. This reconfiguration (engine's behavior) must not be confused with an actual problem in driveability, which occurred before the reconfiguration.
- **Slower throttle opening than the requested throttle opening.** The throttle opens more slowly than normal requested opening because the system is only regulated by the pulse width modulated signals from the accelerator pedal position sensor. The driver may notice that the engine responds slightly slower than at normal acceleration.
- **Throttle closure when braking.** The accelerator pedal position is ignored when the brake pedal is depressed.
- **The throttle follows the accelerator pedal position.** The throttle and accelerator pedal are used as if they were mechanically connected to each other. This reconfiguration is always determined by fuel-shut off as above.

- **Throttle closed.** The Electronic throttle module (ETM) switches off the throttle motor's control, which means that the throttle is not affected and therefore returns to the mechanical stop position. This means approximately 20 % throttle opening. This reconfiguration is always determined by fuel shut-off as above.
- **Cruise control off.** The cruise control is off during the operating cycle when the fault was detected. The function is available at next start-up if the fault is no longer present.
